The conference will be held May 1 and 2 at the Carnegie Institute of Technology in Pittsburgh. President Arthur Hamerschlag of this institution is a member of the committee which is composed of prominent deans of schools of engineering, and of commerce in our larger universities, and of engineers and business men who are nationally known for their interest in the reduction of the costs of production, distribution, transportation, etc., through better training in schools and colleges of the personnel of industry and commerce.

The conference will be open to the public. Invitations to appoint delegates to the Pittsburgh Conference, however, will be sent by the Commissioner of Education to commercial and trade organizations, engineering and scientific societies, educational institutions and other groups as well as to prominent individuals.

Owing to the timeliness of the subject, the conference in Pittsburgh will even have greater national significance than the first public conference on this question, which was held in Washington two and one-half years ago under the direction of this committee on commercial engineering of which Dr. Glen Levin Swiggett of the Bureau of Education is chairman.

Outstanding topics at the Pittsburgh Conference will deal with the new problems that have recently arisen in modern industries, the solution of which demands a more scientific approach to include job analyses and personnel specifications and a translation of these for use in our engineering and commerce schools; and with the training of the engineer for a better understanding of problems of community development.

Test Code for Hydraulic Power Plants and Their Equipment

Preliminary Draft of the Sixth in the Series of Nineteen Test Codes Being Formulated by the A.S.M.E. Committee on Power Test Codes

By action of the Council of The American Society of Mechanical Engineers at its meeting in December, 1917 a Joint Committee organized for the purpose of revising the A.S.M.E. Test Code on Water Wheels was approved. Since that time a Committee of twelve and recently thirteen specialists in Hydraulics have worked diligently at this revision. These men represented respectively the American Society of Civil Engineers, the American Institute of Electrical Engineers, the National Electric Light Association, and The American Society of Mechanical Engineers.

In December, 1918, when the enlarged Committee on Power Test Codes was organized and eighteen Individual Committees appointed, by mutual consent, the Committee on Hydraulic Power Plants became No. 18 of this group. The representatives of the four Societies on this Individual Committee are as follows: *A.S.C.E.:* Nathaniel A. Carle, Benjamin F. Groat,[1] and Clemens Herschel; *A.I.E.E.:* Harold W. Buck, Henry S. Putnam, and Philip Torchio; *N.E.L.A.:* Charles M. Allen, Markham Cheever, and J. A. Walls; *A.S.M.E.:* John L. Harper, Raymond D. Johnson, Chester W. Larner, and William F. Uhl. Mr. Uhl is Chairman of the Committee and he will be glad to receive suggestions for corrections and additions to this draft of its Code. These should be addressed to him care of The American Society of Mechanical Engineers.

Introduction

1 Tests of hydraulic power plants relate either to the entire plant, extending from head water to tail water, or to any elementary part or parts of the plant desired. For the purpose of such tests the plant may be divided into six distinct parts, and these may be grouped into three divisions as follows:

Head-Water Division:

(*a*) That lying upstream from the forebay
(*b*) That lying between the forebay and the entrance to the wheel flume or wheel case

Turbine Division:

(*c*) The wheel case and speed ring
(*d*) The runner and guides or nozzles
(*e*)[1] The draft tube. For the purposes of this code the draft tube subdivision shall be considered to be that portion of the hydraulic system extending from the turbine runner to the point of maximum elevation (beyond and exclusive of local surface of disturbances) of the tail water and shall not necessarily terminate at the end of the physical draft tube.

Tail-Water Division:

(*f*) The tail-race.

2 Some of the individual parts noted may be absent from certain classes of hydraulic plants, but all parts of every plant may be logically included in the main divisions given. Figures 1, 2 and 3 illustrate typical conditions.

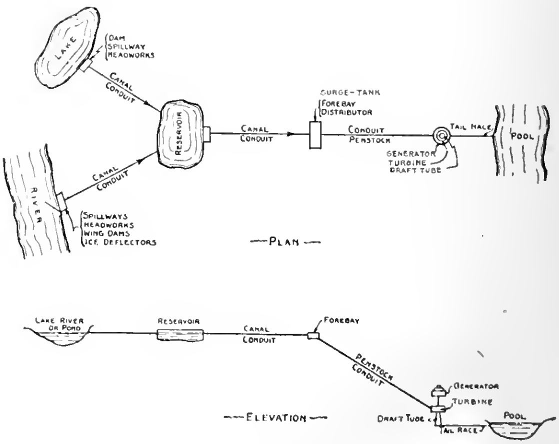

Fig. 1

3 The tests may be either *laboratory* or *field* tests, and as such may cover any part or parts of the plant. They may also be combined *laboratory and field* tests, including tests of a turbine model used as a representative substitute of the existing turbine, being con-

---

[1] In signing the report of the Committee Mr. B. F. Groat has made the following reservations.

Par. 1, 2 and 3. I do not agree to the methods of treating the draft tube subdivision in this proposed statement of the code. There is an accepted definite hydraulic theory which may be practically applied to the physical end of a draft tube to determine accurately the full amount of energy being discharged by the draft tube, and any code for testing should set this forth clearly and should limit the amount of energy passing the physical end to reasonable proportions, or, otherwise state, as one of the results of the test, the amount of excess energy discharged in a unit of time which should be entered in the record as a loss of efficiency. This loss of efficiency may be chargeable to the turbine, to the method of its operation, or to the draft tube or other imperfection, or to a combination of these imperfections. It is the province of the test to determine how much this loss in efficiency is. If the loss is within reasonable limits it is passable. If not, it is the province of experts to say how the losses should be divided among the offending elements of the plant.

I cannot agree to the addition of the velocity-head in the tail race to the tail race level because this credits as useful work what otherwise would be a loss. This amount of loss should appear in every report of a test and appear as a loss, whether it be charged against the turbine, the draft tube, or other part of the plant. To add this velocity head to the tail race level completely buries it from the view.

Par. 1*e*. In my opinion the over all efficiency of a hydraulic power plant should be measured beyond the point of a maximum elevation of the tail water in the tail race or tail pond so as to obtain the elevation of the water surface therein uninfluenced locally by disturbances emanating unduly, from the plant. When the plant is properly designed the point of maximum elevation in the tail race, or tail pond, will lie substantially in the surface of the surrounding water and there will be no "point of maximum elevation of the tail water." When the test is of the turbine the loss ought to be measured at the physical end of the draft tube and the allowable loss limited as suggested above.

Par. 5*e*. A positive statement should be made that current meters in disturbed water do not adhere to their still water ratings. This is one of the most certainly established facts of engineering. It should also be stated that the current meter offers one of the most accurate methods of measuring water when care is taken to correct the record by means of ratings in turbulent water. Cup meters are prone to over-register while screw meters are prone to under-register. Surely one of the important offices of the code is to warn the testing engineer of the possible source of error in his instruments and methods.

While I do not want in any way to inject my personal methods into the code unduly, I feel that it may be permissible for me to explain that I have treated a mass of flowing water as a mass of disturbances, these disturbances forming an *aggregate* which may be measured by its effects of one kind or another, say upon the current meter. I have shown by experiment that a certain proportion of transverse motion in turbulent water has, with respect to the longitudinal motion, fixed effect in accelerating a cup meter of given type, and a fixed counter effect in retarding a screw meter of given type, with reference to their still-water ratings no matter whether the transverse disturbances are large or small, frequent or infrequent. That the divergence between the records of the two types of meter is an accurate means of determining the relative amount of turbulence in the water, and an accurate means of correcting the divergent records so as to determine the true velocity.

Par. 18*b* (2). I agree to the definition of "effective head" as in 18*b* only when there are definite and reasonable limitations to the amounts of the losses which are credited to the plant, or part thereof, by a blind application of this definition. If, for example, the division of the plant is a conduit, then the energy leaving should be as large as possible. If it is a turbine, the energy should be as small as possible when leaving. No code for testing hydraulic plants should fail to make clearly expressed distinctions and reasonable allowable limitations in the two cases. A code of testing should supply correct rules for detecting and determining the true losses in the various portions of the plant. It should also state the reasonable limitations to the various losses so that there will be some showing up of excessive losses. Losses at the end of a draft tube should be limited to the head due to 4 feet per second, or some other reasonable amount. Losses in a conduit should be limited by specifications as to hydraulic slope per foot of length of conduit.

Par. 18*b* (2). I do not agree that in the case of an open flume turbine the velocity of the water coming into the turbine flume should not be considered in determining the effective head. I disagree on grounds similar to those stated above relative to the determination of tail water level. This is a deceptive piece of antiquated engineering that should not be allowed in the code, especially if the combined efficiency of the flume and turbine are to be determined. The velocity-head within the flume should be charged as effective head. Every part of the hydraulic energy that comes to a plant should be charged against that plant in a full statement of the conditions. Nothing is gained by deceiving ourselves into the belief that our works are more efficient than they are.

structed in all respects homologous thereto, and the results being corrected for dissimilar conditions. A laboratory test is one made on apparatus not installed in its final position. A field test is one made on apparatus installed in its permanent location in the plant.

OBJECT

The object of a test made under this Code is primarily the determination of the energy losses in any part or parts of the plant for the purpose of determining the degree of fulfillment of the performance guarantees between builders and users; or for determining how a greater portion of the potential water power available can be converted into useful work; or how combined operation of units or plants may be most effectively conducted.

See Code on "General Instructions."

MEASUREMENTS, WATER

5 On account of the difficulty in making accurate water measurements, every practicable means of checking the quantities measured should be utilized and if feasible more than one method should be employed for comparison with the results of the specified method. The standard method of water measurement is by volume or bulk. By comparison with this method the rating of any other method may be determined.

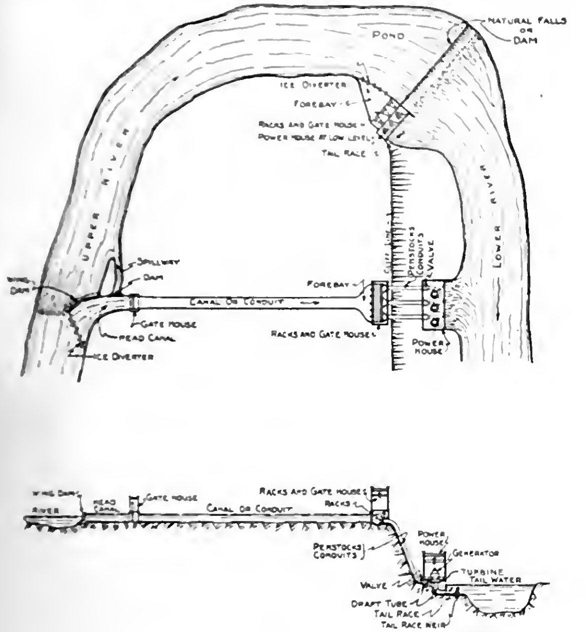

FIG. 2

MEASURING WATER IN CLOSED CONDUITS

5a *Venturi Meter.* The venturi meter is adapted for use in conduits in which the flow is not unduly disturbed by bends, sudden changes of section or obstructions near the upstream end of the meter. A commercial meter may be installed as part of the original plant or later by removing a portion of the conduit. If the conduit is large enough to work in, a temporary meter may be constructed of wood or other suitable material inside the conduit.

5b *Pitot Tubes.* Pitot tubes may be employed in conduits where conditions are substantially as described under Par. 5a, but pitot tubes are more sensitive to the disturbing effects of bends, sudden changes of section and obstructions than the venturi meter.

5c *Salt Solution.* The salt solution method may be advantageously employed in conduits where the conditions of flow are too disturbed or the conduits are too short to permit the use of the venturi meter or pitot tubes.

MEASURING WATER IN OPEN CONDUITS

5d *Weir.* This method is adapted for use in open conduits wherever the plant is so arranged as to permit the construction of a weir of proper length with a suitable channel of approach, and provided further that the use of the weir does not change the head on the turbine in excess of the limits provided in Par. 11.

5e[1] *Current Meter.* Current meters may be used in open conduits which are free from serious disturbances such as cross currents and eddies. They are adapted to many cases where the use of the weir is impossible.

5f *Salt Solution.* This method is applicable to practically all conditions of flow in open conduits. It is especially advantageous in cases where the flow is disturbed and may be used under conditions which would not permit the use of current meters or a weir.

MEASURING WATER—SPECIAL METHODS

5g *Special Methods.* The following methods or means employed for water measurement may sometimes be used, but they are subject to limitations and are available only under special conditions. Some of them have not yet been checked sufficiently by accepted methods to permit their use alone.

(1) Traveling screen
(2) Volumetric or bulk
(3) Color method
(4) Brine velocity

MEASUREMENTS, HEAD

6 Head measurements consist of the determination of:

(*a*) Gross Head
(*b*) Net Head

6a *Gross head.* The determination of the gross head consists of measurements of difference of elevation between two water surfaces.

Preparations for measuring the gross head require

(1) Establishing bench marks from which the elevation of the water surfaces may be determined by differential leveling.

(2) Providing gage boards and setting them by differential leveling. From these the elevation of the water surfaces may be obtained by direct reading.

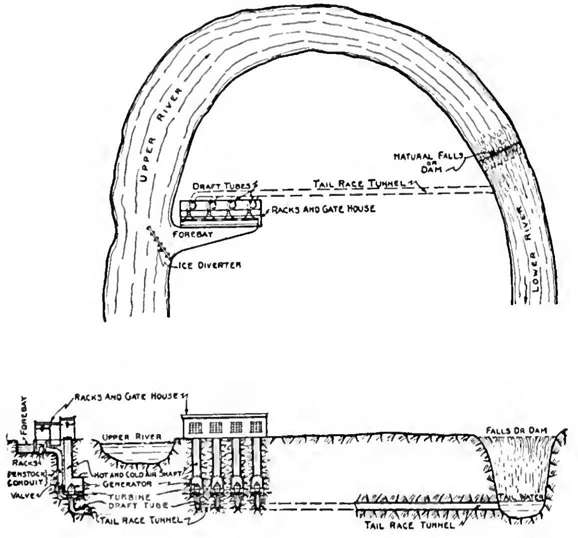

FIG. 3

(3) Providing stilling boxes and hook gages at points of desired measurements, and referring them to the bench marks.

6b *Net Head.* The determination of the *net head* consists of measurements establishing the difference in elevation of the points between which the net head is to be determined and measurement of areas of the conduits at these two points, by means of which the velocity head can be computed. The preparations required for determining the net head acting on a turbine are as follows:

(1) *Open-Flume Turbines.* Provide board, rod or float gages in the open turbine flume, and if practicable near the center of the setting, and similar gages in the tail race, all gages being located at points reasonably free from local disturbances. Gages are to be placed so as to be uninfluenced by velocity effects. If this is impracticable when the gages are set in the open channel, they should be placed in properly arranged stilling boxes. When stilling boxes are used, the communication between the box and channel should consist of one or more piezometer openings in a plane surface parallel to the flow, thereby avoiding velocity effects. When board gages are used at the side of the channel, they should be flush with the wall surface.

(2) *Encased Turbines.* Measure the area of the casing intake, provide piezometers at this point and connect them to separate gages. If spring gages are used, the elevation of the center of the dial is to be determined, and such gages are to be piped so that the air can be absolutely removed from the pipe leading to it. The piezometer orifices should be approximately $^1/_8$ to $^1/_4$ inch in diameter. Provide also a gage of either the board, rod or float type and locate it in the tail race at a point reasonably free from local disturbances, and otherwise following the directions given above for the open-flume turbines.

---

[1] See footnote, page 248.

Measurements, Speeds

7 There are two methods of speed determination.

7a *The Speed of Revolution* of a shaft is determined by means of a hand revolution counter and a watch, or a recording revolution counter. For accurate work and in all cases for low speeds a stop watch and revolution counter must be used.

7b A *Recording Speed Indicator* is used to obtain the average speed during a test run covering a considerable time interval in place of a series of readings at regular intervals or to determine the variation of speed for governor tests.

Measurements, Power

8 There are two methods available for measuring the power, viz., the *dynamometer method* and the *electric method*.

In addition to the power so measured, there may be other quantities of power to be included with the power supplied by the turbine shaft, such as the power for the governor pumps when driven by the turbine shaft.

8a *Dynamometer Method.* The dynamometer method is suitable where the turbine drives equipment which cannot be used to measure power or in the case of hydroelectric plants where the generator efficiency is unknown or known for only one speed where knowledge of the variable speed characteristics is desirable.

8b *The Electric Method* is applicable to hydroelectric plants, the power of the turbine being computed from the electric output. The power delivered to the generator shaft is determined by adding to the power output at the generator terminals all other power furnished by the shaft, such as generator losses that are absorbing power directly from the shaft, or power for operating exciters which are driven by the shaft; all of these items to be measured or calculated in accordance with the lastest A.I.E.E. Standardization Rules.

The power determined above is equal to the power delivered to the generator by the turbine shaft when connected direct to the generator shaft, but must be increased by the losses of any intermediate transmitting device, such as a gear or belt drive.

In cases where the turbine supplies the power for extra ventilation for the generator, it may or may not be necessary to treat the power for ventilation independently as part of the output of the turbine. Such amounts of power must be handled consistently with the specifications relating to the generator tests and generator efficiency.

Reduced or negative windage, if any, due to extra ventilation should be considered in determining the generator losses.

Instruments and Apparatus

9 The apparatus and instruments required for the various measurements noted are herewith summarized for convenience of reference. Directions for the use and calibration of these instruments and appliances are given in Par. 101 to 197 of the Code on "Instruments and Apparatus."

9a *Measuring Water*
  (1) Venturi meter
  (2) Salt solution
  (3) Pitot tube
  (4) Weir
  (5) Current meter
  (6) Special methods.

9b *Measuring Head*
  (1) Direct measurements
  (2) Float gage
  (3) Hook gage
  (4) Stilling box
  (5) Pressure gage
  (6) Board gage
  (7) Piezometer.

9c *Measuring Speed*
  (1) Hand revolution counter
  (2) Continuous revolution counter
  (3) Electric speed indicator.

9d *Measuring Power*
  (1) Dynamometer
  (2) Electric load.

Operating Conditions

10 Determine what the test operating conditions should be to conform to the object in view and see that they prevail throughout the trial. As the head on a water-power plant is rarely constant throughout an extended period of time, the working head during the test may be different from the head for which the turbine was designed or under which guarantees were made. In such cases it is necessary, especially in acceptance tests, to correct by computation the results for this deviation of head.

11 Acceptance tests should be made, if possible, under the head and at the speed specified in the contract. The net head shall not differ from the specified head by more than 10 per cent unless the speed of the turbine shall be adjusted to correspond to the head under which the test is made. If the speed is changed in proportion to the square root of the head, the horsepower output will change in proportion to the three-halves power of the head, and the turbine efficiency may be assumed to remain the same for a range of head variation of 15 per cent.

12 Fluctuation of load during any single run of an acceptance test must not exceed 5 per cent above or below the prescribed load. The head under which a test run is made shall not vary more than 2 per cent from the head for which the proper speed has been fixed at the beginning of the run. If these limitations cannot be complied with by the use of the commercial load, an artificial load must be provided.

13 Apparatus installed for purposes of test must be arranged so as not to affect the performance of the turbine or other parts of the equipment under test. If this cannot be done, a special experiment must be made to determine the effect of removing and replacing the apparatus in question and a proper allowance made therefore.

14 The unit under acceptance test must be in normal operating condition throughout the test, and must have been operated under load for an aggregate time of at least three days prior to the test if so required by either party. A careful inspection should be made of the turbine before and after the test to determine that the water passages are free from obstructions and all parts in normal operating condition.

Duration

15 The duration of an efficiency test depends mainly upon the method of water measurement employed. Sufficient time must be allowed to obtain a requisite number of observations to insure a reliable average.

Records

16 A sufficient number of blank tables should be prepared for every observer, and the readings taken by the individual observers should be entered in a table or log of data and results immediately after making the test. All readings should be taken against time and also by signal where there is some special reason for signal readings. Instrument calibrations and correction curves should be prepared in advance of the test, and measures taken to enable results to be computed as quickly as possible during the course of the test or before the work of testing shall be considered to have been completed. If this rule is carried out, errors will generally be detected in time to correct the readings in question at once.

17 In order to avoid the possible necessity of throwing out an entire series of observations due to some one or more errors, it is advisable that the computations and the plotting of results be completed as soon after the observations are taken as possible. If this is done before leaving the test room and particularly before removing the test apparatus, the observations in question can be repeated without much difficulty.

Calculations of Results

18 The method of calculating the leading data and results are given below under the following headings:

(*a*) Rate of flow
(*b*) Head
(*c*) Power
(*d*) Efficiency.

18a *Rate of flow.* This is obtained either by the velocity-area method, which involves the determination of the mean velocity of the water, and with the cross-sectional area of the conduit known, the rate of flow equals the product of the two factors; or by the direct-discharge methods, which require the determination of the weight or volume of water flowing in a given time.

18b *Head.*

(1) Gross or Total Hydrostatic Head. This is obtained by taking the difference in elevation between the head water surface and tail water surface of a hydraulic power plant when the plant is not in operation.

(2)[1] Net or Effective Head. The effective head acting on a plant or division of a plant is the pressure head (if a closed conduit) or elevation of the water surface (if an open conduit) at the entrance section, plus the velocity head at this point, less the sum of the pressure head or elevation of the water surface and velocity head at the discharge section of the plant or division of the plant in question when the plant is in operation.

---

[1] See footnote, page 248.

In the case of an open-flume turbine the velocity of the water coming into the turbine flume is not considered as being effective and the effective head on the turbine in that case is the difference in elevation between head water in the flume near the center of the turbine and the tail race at the end of the draft tube sub-division, less the velocity head at the latter point.

In the case of an encased turbine the velocity of the water entering the casing is considered to be effective and the effective head on the turbine in that case is the pressure head plus velocity head at the casing intake plus the difference in elevation between the point of measurement and the end of the draft tube sub-division, less the velocity head at the latter point.

In the case of an impulse wheel or turbine without a draft tube the effective head on the wheel or turbine shall be considered to be the pressure head at the nozzle plus the velocity head at this point plus the elevation of this point above the tail water.

18c *Power*

(1) *Potential Energy.* The total potential energy of any hydraulic plant or any part thereof is that latent in the available rate of flow of water due to the difference of elevation (Par. 18b) between the upper and lower ends of the plant or part thereof.

The rate of work in horsepower (theoretical horsepower) is expressed as follows:

$$\text{T.hp.} = \frac{Q \times W \times H}{550}$$

where Q = cu. ft. per sec.
W = weight per cu. ft.
H = gross head as defined in Par. 18b.

(2) *Water Horsepower.* The available water horsepower is found by the following formula:

$$\text{W.hp.} = \frac{Q \times W \times \text{effective head}}{550}$$

where Q = cu. ft. per sec.
W = weight per cu. ft.

(3) *Brake Horsepower.* The brake horsepower is the power delivered by the turbine shaft. Power measuring methods are summarized in Par. 9d.

In the case of direct-connected hydroelectric units, the delivery of power (b.hp.) from the turbine is considered to be at a point on the turbine shaft beyond which the turbine manufacturer furnishes no bearings, or beyond which he has connected no power-consuming devices.

As an illustration of this, take the case of a single vertical direct-connected three-guide-bearing unit with thrust bearing mounted on top of the generator. If the turbine manufacturer furnishes only the lower guide-bearing, the power is to be assumed as delivered between the turbine guide bearing and the lower generator bearing. If the turbine manufacturer furnishes two bearings beyond the runner, then the power is assumed to be delivered beyond the second bearing.

18d *Efficiency.* The efficiency of a hydraulic plant or any subdivision of the plant is the ratio of the energy made useful, to that which is available. For some parts of the plant the efficiency may be expressed directly in terms of ratio of heads, the losses which occur when there is no leakage being losses of head. For parts of the plant including the turbine it must be expressed as a ratio of powers. Where there is leakage, a correction must be made for the power corresponding to the loss thus sustained.

The various efficiencies are defined as follows:

(1) *Plant Efficiency.* The plant efficiency is the relation expressed as a ratio of "brake horsepower" developed by the turbine to "theoretical horsepower" of the water, or

$$\text{Plant Efficiency (expressed as a percentage)} = \frac{\text{B.hp.}}{\text{T.hp.}} \times 100.$$

(2) *Turbine Efficiency.* The turbine efficiency is found by the following formula:

$$\text{Turbine Efficiency (expressed as a percentage)} = \frac{\text{B.hp.}}{\text{W.hp.}} \times 100.$$

(3) *Part-Plant Efficiency.* The efficiency of any part of the plant not including the turbine, is the ratio of the W.hp. at the point of discharge to the W.hp. at the entrance. If there are no leakage losses between these two points, the efficiency may be expressed as a direct ratio between the effective heads at the two points.

The efficiency of any part of the plant including the turbine is the ratio of the b.hp. delivered by the turbine shaft to the available W.hp. entering that part of the plant for which the efficiency is desired.

DATA AND RESULTS

19 The data and results of the test are to be reported in accordance with the appended forms, the first of which, Table 1, gives the general data covering the leading features and dimensions of the entire plant; and the second, Table 2, a summary of the principal quantities and leading results.

TABLE 1 GENERAL DATA CONCERNING PLANT

HEAD-WATER EQUIPMENT

(a) *Reservoir*

(1) Name..........
(2) Distance from power plant..........mi.
(3) Area at surface of full reservoir..........acres
(4) Area at each foot of depth..........acres
(5) Draft..........ft.
(6) Capacity..........cu. ft.
(7) Outlet area..........sq. ft.

(b) *Pond*

(8) Surface area of full pond..........sq. ft.
(9) Elevation of surface of full pond..........ft.
(10) Draft..........ft.
(11) Capacity..........cu. ft.
(12) Spillway length..........ft.
(13) Elevation of crest of spillway..........ft.

(c) *Closed Conduits*

(14) Area of intake..........sq. ft.
(15) Area of conduits..........sq. ft.
(16) Length..........ft.

TAIL-WATER EQUIPMENT

(d) *Open Conduits*

(17) Area of intake..........sq. ft.
(18) Area of conduit with full discharge..........sq. ft.
Area of conduit with part discharge..........sq. ft.
(19) Wetted perimeter..........ft.
(20) Length..........ft.
(21) Depth with full discharge..........ft.
(22) Slope..........ft. per 100

(e) *Forebay*

(23) Area with full pond..........sq. ft.
(24) Net rack area..........sq. ft.
(25) Net area of intakes..........sq. ft.
(26) Submergence of top of intake with full pond..........ft.
(27) Elevation of crest with full pond..........ft.
(28) Spillway length..........ft.
(29) Elevation of crest of spillway..........ft.

(f) *Penstocks*

(30) Inlet area..........sq. ft.
(31) Net area of penstock (average area if of variable diameter) sq. ft.
(32) Length..........ft.
(33) Area at turbine connection..........sq. ft.

(g) *Standpipe*

(34) Distance from turbine..........ft.
(35) Type (open, tank, differential, etc.)..........
(36) Net area at penstock connection..........sq. ft.
(37) Net area at tank..........sq. ft.
(38) Net area at throttle if any..........sq. ft.
(39) Elevation at connection to penstock..........ft.
(40) Elevation of top..........ft.
(41) Elevation of overflow..........ft.
(42) Overflow area with 1 ft. discharge depth..........sq. ft.

TURBINE EQUIPMENT

(h) *Open-Flume Settings*

(43) Net rack area per unit..........sq. ft.
(44) Intake area..........sq. ft.
(45) Dimensions of flume..........
(46) Submergence of turbine..........ft.
(47) Type of turbine..........

(i) *Encased Settings*

(48) Type of casing (cylindrical, spiral, etc.)..........
(49) Area of inlet..........sq. ft.
(50) Diameter of casing..........ft.
(51) Length of casing..........ft.
(52) Area of spiral at several points..........sq. ft.
(53) Type of turbine..........

(j) *Turbine Runners*

(54) Reaction or impulse..........
(55) Kind of buckets..........
(56) Material of runner or disk..........
(57) Inlet depth of buckets..........in.
(58) Total discharge area of buckets..........sq. in.
(59) Nominal diameter of runner..........in.
(60) Maximum discharge diameter..........in.

(k) *Turbine*

(61) Type (Whether horizontal or vertical, reaction or impulse, open-flume or encased, cylindrical or spiral casing, needle or deflecting nozzle, swivel or cylinder gate, single or multiple runner, outside or inside gate mechanism, etc.)..........
(62) Rated capacity under.....ft. head..........b.hp.
(63) R.p.m. at rated capacity..........r.p.m.
(64) Maximum gate opening..........in.
(65) Maximum net nozzle area..........sq. in.

(l) *Draft Tube*

(66) Area at runner discharge..........sq. ft.
(67) Area at outlet..........sq. ft.
(68) Maximum gross draft head..........ft.
(69) Minimum gross draft head..........ft
(Distance from center of shaft or bottom of runner to lowest and highest tailwater, for horizontal or vertical turbines, respectively.)
(70) Length of draft tube (on center line)..........ft.
(71) Area of tube at several points..........sq. ft.

Tail-Water Equipment

(m) *Tail Race*
- (72) Cross-sectional area at draft tube........................sq.ft.
- (73) Depth ....ft.
- (74) Wetted perimeter ....ft.
- (75) Surface slope .. ..ft. per 100

Load

(n) *Mechanical*
- (76) Kind (industrial, brake, dynamometer, etc.) .....
- (77) Capacity.......................................

(o) *Electrical*
- (78) Kind (industrial, water rheostat, etc.).......
- (79) A.c., or d.c. generator........................
- (80) Capacity (A.I.E.E. rating)....kw. or....kva ....
- (81) Frequency...............................cycles
- (82) Phase..
- (83) Voltage.......................................volts
- (84) Efficiency of generator at various outputs and various power factors, if a.c.........................per cent
- (85) Exciter capacity......................................kw.
- (86) Exciter voltage.................................. volt.

Auxiliary Equipment

(p) *Governor*
- (87) Capacity...ft-lb.
- (88) Type (oil-pressure, water-pressure or mechanical).............
- (89) Governing system (unit or central) ....
- (90) Pressure system (open or closed)...........................
- (91) Working pressure..lb.
- (92) Closing time (full stroke)........ ....sec.
- (93) Opening time (full stroke).............................sec.
- (94) Difference in speed between no load and full load.....per cent
- (95) Capacity of oil pump..........................gal. per min.
- (96) Volume of pressure tank ....cu. ft.
- (97) Volume of receiving tank.............................cu. ft.
- (98) Diameter and length of pipe:
  - (a) Between pressure tank and regulating valve......in.....ft.
  - (b) Between regulating valve and cylinder...........in.....ft.
  - (c) Between regulating valve and receiving tank.....in.....ft.
  - (d) Between pump and pressure tank...............in.....ft.
  - (e) Between pump and receiving tank.............in.....ft.
- (99) Flywheel effect
  - (a) Of turbine rotating parts (Wr^2)....................ft²-lb.

Sections of Code on Instruments and Apparatus Referring to This Test Code

Power Measuring Apparatus

101 There are two types of apparatus used to measure the power output of a hydraulic turbine, *viz.*, dynamometers and electric generators, that are direct connected to the turbine shaft. The latter apparatus is preferred to dynamometers on turbines that are used to drive electric generators.

Dynamometers

102 Dynamometers are of two general types; *viz.*, *absorption dynamometers* which absorb the power by mechanical or fluid friction and dissipate it as heat, and *transmission* dynamometers, which transmit or pass along the power they measure, wasting only a small part in friction.

103 The absorption dynamometers are represented by the following:

Prony brake, which is limited to small amounts of power.

Aldendynamometer, which is an improved form of Prony brake and is of much greater capacity.

Froude or ***Water Brake***, which is suitable for higher speeds than the other two.

Electric Generators

104 Whenever an electric generator is used for measuring the power output of the turbine the electrical output of the generator divided by its efficiency represents this power. The generator output is measured during the test of the turbine. The efficiency should be obtained from the manufacturer of the generator or by a separate test.

105 It is preferred that the generator efficiency be determined by the manufacturer before leaving the factory under the load, voltage and speed conditions duplicating those obtained during the test of the turbine, if the manufacturer's data are dependable. Otherwise, the generator efficiency should be determined for the loads, voltages and speeds to be obtained when testing the turbine, by the separate-loss method, the electrical measurements being made in accordance with The Standards of the American Institute of Electrical Engineers, 1921 Revision, Sections 4334–4342. In determining the generator efficiency by the separate-loss method it is calculated by dividing the generator output by the sum of the output and the various generator losses.

106 When practicable the generator, if of the alternating current type, is to be separately excited during both generator and turbine power tests, and the excitation loss is not to be included in computing generator efficiency, and is therefore, also to be omitted in computing power output at the turbine coupling. If the main generator is excited from a direct connected exciter or from an exciter belted from the shaft of the unit, the power of which is to be measured, then to the output of the main generator, computed without reference to excitation, there is to be added the output of the exciter divided by its efficiency; and in the case of the belted exciter, the belt losses

are to be added. It is preferable, for simplicity, that when possible the current for excitation shall be obtained from a separately driven exciter.

107 The losses in a constant-potential synchronous generator are of two classes; namely, those which remain substantially constant at all loads and those which vary with the load. The former include core losses, windage and friction. The latter include I^2R losses in the armature winding. The simple method of determining the losses and hence the efficiency is only approximate, since the losses which are assumed to be constant do actually vary to some extent with the load, and also because the actual I^2R loss in the armature windings is sometimes appreciably greater than the calculated I^2R loss. The difference between the approximate losses and the actual losses is termed "stray load losses." These latter are due to distortion in electric or magnetic fluxes from their no-load distributions or values brought about by the load current. They are usually only approximately measurable, but are of sufficient magnitude to require consideration when determining generator efficiency by the separate-loss method.

108 When determined by the separate-loss method, the generator efficiency, in the case of polyphase alternators separately excited, is to be taken as

E = [(kw. output at terminals)] divided by [(kw. output) plus (friction and windage) plus (I^2R loss in armature) plus (stray load losses)] all losses being expressed in kilowatts.

Kw. Output

109 The kw. output of the generator should be measured by a polyphase wattmeter and the necessary instrument transformers at the generator terminals.

Friction and Windage

110 The value of generator windage and friction should be directly measured by driving the generator alone by an independent motor, the output of which shall be determined by multiplying the motor input by its efficiency.[3] The generator shall not be connected to a load or have its field excited. The output of the driving motor will represent the generator loss due to bearing friction, collector ring friction and windage. With units having direct-connected exciters, the windage and friction may be measured by driving the generator by the exciter run as a motor. When the windage and friction cannot be directly measured, it is to be taken either from shop tests of generators of similar design, or from a retardation test made after installation. When possible, more than one method should be used in order to obtain a check. In making a retardation test, the turbine shaft and runner, or the turbine runner, are to be disconnected when practicable from the generator shaft, to enable the windage and friction of the generator alone to be measured. When the turbine shaft or runner cannot be disconnected, the generator windage and friction are to be computed by deducting from the total windage and friction that of the turbine, which for this purpose may be found with sufficient accuracy from the formula:

$$W = KBD^4N^3$$

where W = turbine windage and friction in kilowatts.
K = an empirical coefficient which may be taken as 0.000115, as determined from available test data.
B = height of turbine distributor in feet.
D = entrance diameter of runner in feet at center line of distributor.
N = revolutions per second.

I^2R Loss in Armature

111 The I^2R loss in the armature can be calculated for each load from the armature current and electrical resistance of the armature. This requires the measurement of the resistance by a Wheatstone bridge at various loads. These measurements can be made immediately after the stray load tests (see paragraph 112) for each load, before the resistance has had time to change because of cooling of the generator.

Stray Load Losses

112 The stray load losses which include iron losses and eddy-current losses in the copper, due to fluxes varying with load and also to saturation, shall be determined by driving the generator on short circuit and at the current corresponding with the generator load under consideration. An independent motor, or the exciter if direct connected, should be used to drive the generator, it being necessary to determine the efficiency of the motor as prescribed in the section on Friction and Windage, paragraph 110. The output of the motor driving the generator alone when reduced by the sum of the windage and friction and I^2R losses of the generator equals the stray load loss for the generator at the load corresponding with the generator current.

113 If, under special conditions of an installation, other losses exist, these are to be added to the stray load losses determined above.

Salt Solution Method

114 This method consists of introducing salt at a known rate into a body of flowing water, determining the quantity of salt in the water at a point far enough downstream to insure a thorough mixture with the water to be measured, and calculating from these data the quantity of water flowing between these points per unit of time.

115 The practical details require careful consideration, but when the necessary conditions are properly fulfilled this method of measuring flowing water, especially large quantities, is practical and accurate.

116 Two important requirements are (1) that the salt must be added at a fairly constant rate, and (2) that thorough mixture takes place before the samples are drawn off for analysis.

117 The salt solution method of measuring the flow of water may be conveniently divided into that part of the work which is principally mechanical and that which is principally chemical. The mechanical division embraces the work necessary to prepare the equipment for the introduction of the salt and for taking samples, the preparation of the salt solution to be introduced into the water, its actual introduction into the stream, and the taking of the samples. The chemical division embraces the preparation of the special dilution and the titration of the samples.

118 Common salt, NaCl (a quality known to the trade as "coarse-fine"), is usually employed. The salt is dissolved in water to form a brine before being introduced into the water to be measured.

119 It is desirable to have the initial brine supply highly concentrated but not quite saturated. A solution consisting of 16 lb. of salt per cu. ft. of water is satisfactory. (Specific gravity of about 1.18.)

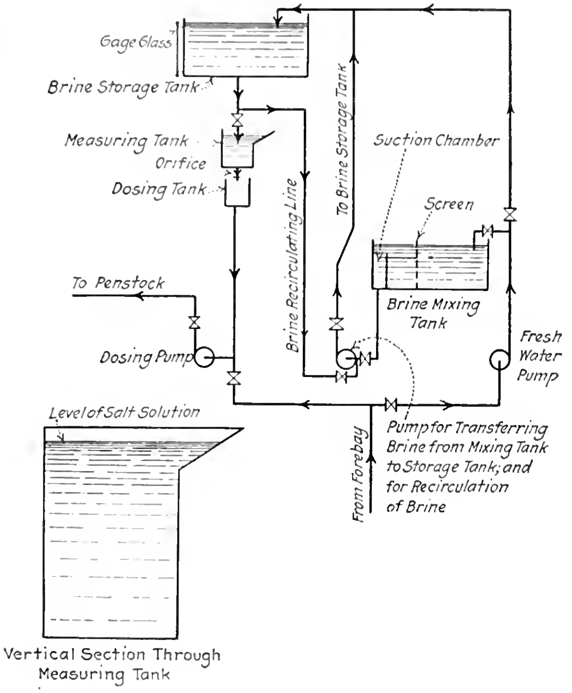

Fig. 101

The apparatus required is as follows:

1 A brine-mixing tank
1-a A brine storage tank
2 A measuring tank with orifice or nozzle
2-a A dosing tank
3 Equipment for introducing the salt solution into the flowing water
4 Equipment for taking samples

120 The brine-mixing tank should be divided into two compartments with screens between them, so that foreign matter which may enter the brine with the salt can be screened out before it enters the storage tank. All tanks should be located so that there will be no danger of the salt or the brine being carried into the water to be measured other than through the measuring tank. A pump will usually be required to supply the water to the mixing tank. The brine storage tank should be elevated above the mixing and measuring tanks.

121 A pump, in many cases the same pump referred to above, will be required in order to pump the brine from the mixing tank to the storage tank. An arrangement of piping is necessary to permit a circulation of the salt solution between the two tanks to insure a brine of equal strength. It is advisable to have the storage tank of sufficient size to hold brine for a number of measurements. A satisfactory arrangement is shown in Fig. 101.

122 One way of getting a fairly constant rate of discharge is to use a measuring tank having an orifice or discharge nozzle. With this the level of the solution in the tank is kept constant throughout a measurement to

---

[3] This necessitates getting from the motor manufacturer data showing the efficiency of the motor at the speeds and loads actually obtained or determining the efficiency by means of a Prony brake test of the motor. During such a brake test the power output and the speed of the motor should be varied while the following data are taken:

If D. C. Motor	*If A. C. Motor*
Brake Horsepower	Brake Horsepower
R.P.M.	R.P.M.
Terminal Voltage	Terminal Voltage
Field Current	Electrical input by wattmeter
Armature Current	

Performance curves should be drawn that will permit of determining the efficiency of the motor when used under any combination of the variables just mentioned.

insure a constant rate of discharge. A projection, having an inclined bottom, on the upper part of one side of the tank, as shown in Fig. 101, accentuates any variation in the level of the solution in the tank.

123 One of the following two means of introducing the solution from the discharge orifice or nozzle into the stream of water to be measured may be necessary.

124 (1) Where the distance between the point of introducing the salt solution and the point where the samples are to be taken is great and if the water is more or less turbulent, the solution may be introduced without much effort to attain uniform distribution, especially if the flow is concentrated in a closed pressure conduit.

125 (2) Where the distance is short, every effort must be made to introduce the solution uniformly over the whole area of the canal or conduit in which the water flows, and some regard must be taken of the unequal velocities in the stream. Sometimes the solution is introduced through a series of pipes having numerous small orifices, the pipes and orifices being distributed to suit the flow. To insure sufficient discharge and also to insure a thorough mixture, a pump should be installed between the dosing tank and the point of introduction into the conduit. The pump suction in addition to drawing brine from the dosing tank obtains its main supply from the conduit or canal in which the water to be measured flows and from a point upstream from the point of introduction. The pump suction head must be reasonably uniform and the level of the dosing tank must be maintained by means of a throttle valve. The horizontal cross-section of the dosing tank should be small, in order to exaggerate changes of level resulting from fluctuations in the rate at which brine is supplied.

126 The introduction of the salt solution into the distributing system under high pressure is favorable to a uniform mixture and the solution shall be introduced under sufficient pressure to produce a uniform mixture as shown by the samples taken after mixing. Wherever possible, the brine should be added to the water on the inlet side of the turbine and the final sample of water should be taken on the discharge side of the turbine to insure thorough mixing of the brine and the water.

127 While the salt solution is being introduced, samples should be taken continuously as follows:

(*a*) Sample of salt solution
(*b*) Sample of natural stream water
(*c*) Sample of dosed stream water after the salt solution has become thoroughly mixed with the water in the stream.

128 A sample of the salt solution should be taken continuously from a point as near the dosing pump as possible.

129 The sample of natural stream water should be taken continuously well above the point where the salt solution is introduced and during the period when it is being introduced.

130 The dosed stream sample should be taken far enough downstream and after sufficient lapse of time to insure a thorough mixture and stable conditions. The samples should be continuous over a period of not less than 5 minutes and should be secured by pumping or by means of bottles arranged to fill slowly.

131 Where the sampling station covers a large cross-section samples must be taken from points distributed well over the entire area, until it is found by trial that the distribution is so uniform that samples from a few points are sufficient. Samples should be taken from not less than 6 points and preferably more.

132 It is necessary to make a preliminary investigation to determine the proper place for taking samples of dosed stream water, and the necessary time interval between the time of beginning dosing and taking the samples.

133 The salt solution should be added to the stream of water to be measured at such a rate as to increase its salt content by at least 0.003 lb. per cu. ft. and under no circumstances should the initial salt content exceed 25 per cent of the salt content of the dosed water.

134 The waters of natural streams usually contain an initial quantity of salt in solution, which must be considered in making a correct gaging.

135 The relative salt content of the various samples should be determined by titration against a standard silver nitrate solution by an experienced chemist.

136 *Calculation of Results.* The number of cubic feet per second of water dosed with a salt solution is equal to the ratio of (the weight of the salt introduced per second) to (the weight of a cubic foot of the water multiplied by the weight of salt added per pound of water in a sample of the dosed water).

Let Q = discharge in cu. ft. per second of stream to be measured.
q = cu. ft. per sec. of salt solution introduced.
C = concentration of salt solution in pounds per cu. ft.
C_1 = concentration of salt in the natural stream water in pounds per cu. ft.
C_2 = concentration of salt in the dosed stream water samples in pounds per cu. ft.

Then the following equation may be derived:

$$(Q + q)\ (C_2 - C_1) = q(C - C_1)$$

$$Q = \frac{(C - C_1)q}{C_2 - C_1} - q$$

137 Since concentrations are proportional to the volume of standard silver nitrate solution required to titrate unit volume, we have:

$$Q = \frac{(V - V_1)q}{V_2 - V_1} - q$$

in which,

V = volume of silver nitrate solution necessary to titrate unit volume of concentrated salt solution
V_1 = volume of silver nitrate solution necessary to titrate unit volume of normal stream water
V_2 = volume of silver nitrate solution necessary to titrate unit volume of dosed stream water.

If V is large compared to V_1 and $\frac{(V - V_1)q}{V_2 - V_1}$ is large compared to q, the equation reduces to

$$Q = \frac{qV}{V_2 - V_1}$$

138 A detailed discussion of the sources of error in the measurement of water by chemical gaging and the derivation of the formula given above, together with correction factors to be applied for more precise application of the method, is given in a paper by B. F. Groat in Trans. American Society of Civil Engineers, Vol. 80.

Pitot Tube

139 The measurement of flow of water by means of pitot tubes cannot be regarded as an extremely accurate method on account of the difficulty of duplicating the conditions under which the tube is calibrated with the conditions under which it is used. A tube properly calibrated in straight-line flow or in still water will give accurate determinations when used at the same velocities in a pipe in which the flow is free from whirls or eddies, but strictly speaking such conditions are never attained even in long straight pipes. Furthermore, the degree of disturbance cannot be observed or determined. The best that can be done is to calibrate the tube for straight-line flow and to use it only under conditions where reasonably straight and smooth flow may be expected to occur. The resulting error, although undeterminable, will then be small. (The magnitude of the error will be given in a later issue.)

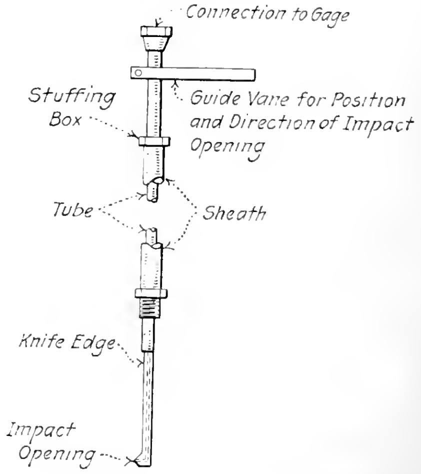

Fig. 102 Single Opening Pitot Tube

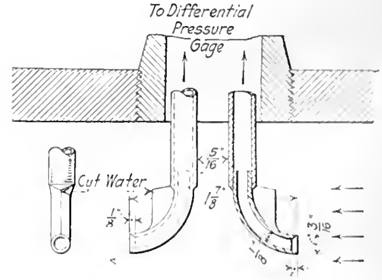

Fig. 103 The Pitometer

140 The pitot tube is suitable for use only where the conditions of flow, as indicated by the readings, are reasonably steady. Steady readings are indicative of steady flow. The question of symmetrical distribution of flow in the pipe is not as important as steady flow. Well designed bends of long radius in the pipe will affect the distribution of velocity across the diameter of the pipe for a considerable distance beyond the bend, but this is not necessarily objectionable. It is desirable to have a run of straight pipe, at least 15 pipe diameters long, following short bends, valves and poorly designed intakes, and immediately preceding the pitot tube to minimize the disturbances to flow which may result from such features. The greater the length of the straight pipe ahead of the pitot tube the greater is the probability that parallel stream flow will exist, which will increase the accuracy of the velocity measurement. The uniformity of the readings obtained at the various points on repeated trials is the most reliable criterion by which to judge the character of the indications.

141 The single-opening pitot tube, Fig. 102, in connection with a "wall piezometer," i.e., not less than two pairs of diametrically opposed holes, that transmit only the pressure head of the water, affords the combination of the simplest and most easily constructed instrument. The piezometer holes shall not exceed $^1/_4$ in. diameter, their edges at the inside wall of the conduit shall be sharp and the holes shall be normal to the internal surface of the wall.

142 The "Pitometer," Fig. 103, is a commercial adaptation of the Pitot principle. This instrument, as also all other tubes which are symmetrical, has the advantage of being reversible.

143 Different forms of pitot tubes may be used, provided they are properly calibrated. If calibration is impossible the form of the tube shown in Fig. 102 is to be used. The formula for use with this tube is $v = c \times \sqrt{2gh}$ where $c = 0.98$ and h is the difference in head between the readings of the pressure gage connected to the pitot tube and the one connected to the piezometer, expressed in feet of water. The coefficient for the Pitometer is furnished by the maker.

144 For measurement of water flowing in conduits under pressure, using pitot tubes, at least two tubes should be arranged to traverse two relatively perpendicular diameters. In the case of very large conduits, or those having unsymmetrical shape or flow, pitot tubes should be arranged to traverse the intermediate diameters completely or partially, giving traverses at 45 degree intervals. The piezometers for the various diameters should be connected so that they may be separately read. The conditions of measurement, including velocity distribution, length of straight run of penstock, and condition of piezometer orifices, should be such that no piezometer shall vary in its readings from the average of all the piezometers by more than 10 per cent of the average velocity head. The piezometer orifices should be flush with the inside surface of the penstock wall, and the wall should be smooth and parallel with the center line of the penstock in the vicinity of the orifices. The orifices should be $^1/_8$ inch to $^1/_4$ inch in diameter. The piezometer openings should be spaced around the wall of the conduit at equal angles at a section approximately one foot upstream from the pitot tube section to avoid the effect of the pitot tube supporting structure, the conduit being of uniform cross-section between the piezometer and the points of the pitot tubes.

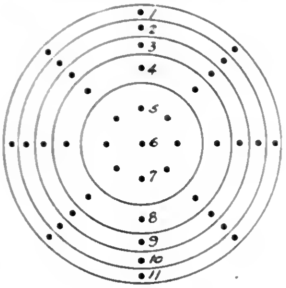

Fig. 104

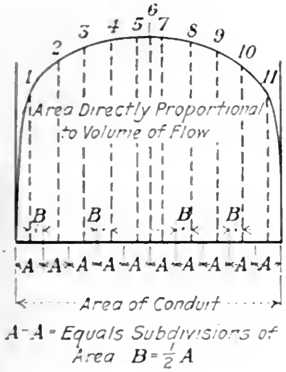

Fig. 105

145 The differential pressures obtained with the pitot tube should be measured as prescribed in paragraphs 191 to 194 of the section on Head-Measuring and Pressure-Measuring Apparatus.

146 Long tubes must be supported to prevent vibration, the support being designed so as to affect the readings as little as possible. In measuring the flow in open channels with pitot tubes, the observations and computations are similar to those used for current-meter measurements, which are described in a separate section.

147 For determining the flow in closed conduits under pressure the area of the conduit is divided into a number of equal concentric areas, the number depending upon the size of the conduit and the degree of accuracy required for the measurement. See Fig. 104. The tube stations are figured to come on the half area point of all the areas, with an extra station in the center of the pipe.

148 A diagram (see Fig. 105) is then constructed having an abscissa representing the conduit area, with vertical lines on the centers of the equal areas. By plotting velocities as ordinates on this diagram, and drawing a curve through the plotted points, the circumscribed area is proportional to the cubic-foot-seconds flowing through the conduit.

Venturi Meter

149 Figure 106 shows a Venturi tube in a horizontal position, with approximate dimensions as generally constructed, although it may be set at any desired angle. For testing hydraulic turbines the velocity through the throat is not to be more than 50 feet per second.

150 Two piezometer tubes are shown in Fig. 106, one at the throat and one at the upstream end of the meter tube. The difference between the indication at the upstream end of the meter tube and that at the throat is used in determining the discharge through the meter tube. The throat velocity with low rates of flow should be great enough so that the difference of pressure heads shown by the piezometers will cause a measurable indication, but should not be so great as to cause the throat pressure to drop below atmospheric, lest there be trouble with air leaking into the tubes.

151 The differential pressures between the inlet and the throat of the Venturi tube should be measured as prescribed in paragraphs 191 to 194 of the section on Head-Measuring and Pressure-Measuring Apparatus.

152 The upstream cone should have a summit angle, which is the angle between wall of the cone and the pipe wall extended, of about 21 degrees. The downstream cone should have a summit angle of not more than 5 degrees. All corners of the main water channels should be rounded. The pressure connections should be made to four or more standard piezometer holes equally spaced around the pipe and staggered with respect to the vertical. Except where standard throats with ring pressure chambers are used the pressure connections are to be connected to read individually or collectively, the object being to obtain the average pressure and avoid dependence on a single piezometer hole, subject to possible local disturbances. The meter tubes are generally made of cast iron but may be made of other materials such as plate steel, concrete or timber. The throat should be of metal accurately bored to size and smoothly finished. It is sometimes desirable to build a Venturi meter of wood, plate steel, or concrete into an existing conduit or in a tail race.

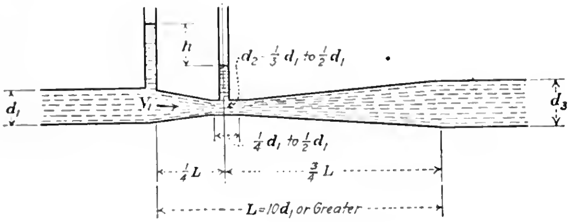

Fig. 6 Venturi Meter

153 The value of C, the "coefficient" of the meter tube, built as above described, is to be taken as 0.99.

154 The formula for calculating the Venturi meter tube discharge is:

$$Q = C \frac{a_1 a_2}{\sqrt{a_1^2 - a_2^2}} \sqrt{2gh}$$

where Q = cu. ft. per sec.

$C = 0.99$, the coefficient of the meter tube.

a_1 = area of the upstream end of the meter tube in sq. ft.

a_2 = area of the throat in sq. ft.

h = differential pressure between upstream and throat piezometers, expressed in feet of water.

155 More accurate results are obtained with Venturi tubes installed so that there are runs of straight pipe on the upstream and downstream sides of at least 8 and 3 pipe diameters, respectively, instead of being installed inside of an existing conduit, which may be of non-circular cross section or of varying cross section.

Weir

156 The weir is a suitable means of measuring the flow of water in open channels when the obstruction of the channel and change of water levels, due to the interposition of the weir, are not objectionable. Many experiments have been made with weirs of different forms, resulting in a number of different formulas for weir discharge. All of these formulas are empirical and require the use of coefficients derived experimentally; consequently the accuracy of the results depends upon the accuracy of the experiments and the use of the formulas and coefficients under conditions identical with those under which the original experiments were made. Weirs carefully used under favorable circumstances are accurate within 1 per cent. Indiscriminate use of weir formulas and coefficients under unsuitable conditions has resulted in much confusion in regard to the accuracy of this method of water measurement.

157 The sharp crested rectangular weir without end contractions, known as the *suppressed weir*, in which the sides of the channel form the ends of the weir, is the basis of the formula and coefficients herein specified.

158 The formula to be used is:

$$Q = C\,L\,h^{3/2}$$

where Q = quantity in cu. ft. per sec.
L = length of weir in ft.
h = difference in level of surface of water upstream (a distance prescribed farther on in this section) and the crest of the weir in feet.

159 The following table gives the values of C for various heads (h) above the crest and heights of crest (P) above the bottom of the channel of approach. See Fig. 107.

160 VALUES OF C FOR VARIOUS HEADS AND HEIGHTS OF CREST P.
P = HEIGHT OF CREST ABOVE BOTTOM OF CHANNEL OF APPROACH

HEAD, h	HEIGHT OF CREST P. (ABOVE BOTTOM OF CHANNEL OF APPROACH), (FT.)										
(ft.)	4	5	6	7	8	9	10	12	14	16	20
1.0	3.376	3.356	3.344	3.335	3.329	3.325	3.322	3.317	3.314	3.311	3.308
1.2	3.391	3.366	3.350	3.339	3.332	3.326	3.322	3.316	3.311	3.308	3.305
1.4	3.409	3.378	3.359	3.346	3.336	3.330	3.324	3.316	3.311	3.307	3.303

161 (To facilitate computations, all corrections for velocity of approach have been included within the coefficients as given. These are therefore to be used in the formula stated above, the observed head being used without modification.)

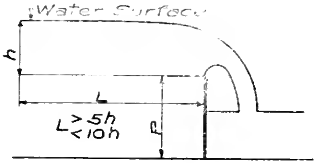

FIG. 107

162 The weir shall, if possible, be located on the tailrace side of the turbine, if used for turbine testing, and care shall be taken that smooth flow, free from eddies, surface disturbances or the presence of considerable quantities of air in suspension, exists in the channel of approach. To insure this condition the weir shall not be located too close to the end of the draft tube, and stilling racks (see Head-Measuring Apparatus) shall be used when required.

163 The channel of approach shall be straight, and of uniform cross-section. Where used, stilling racks shall be arranged to give approximately uniform velocity across the channel of approach. The uniformity of velocity shall be verified by current meter or otherwise.

164 One method of determining the head on the weir or the elevation of the surface of the flowing water, is by direct observation upon it as it flows. The head on the weir may also be observed by hook gages placed in stilling boxes communicating with orifices approximately 1 inch in diameter in the sides of the channel of approach, approximately 1 foot below the level of the crest, the head being observed independently at both sides of the channel. The head (h) on the weir shall be measured at a distance of not less than five nor more than ten times the thickness of the stream going over the weir upstream from the weir. The weir shall be sharp-crested, with smooth vertical crest wall, complete crest contraction, and free overfall. A metal crest free from rust, with sharp right angled corner on the upstream edge, a crest width of $^1/_8$ inch and beveled to an angle of 45 degrees on the downstream face, shall be used. The crest shall be carefully leveled.

165 Complete aeration of the nappe shall be secured and observations of the crest conditions and form of nappe shall be made during the test, to avoid defective conditions such as adhering nappe, disturbed or turbulent flow, or surging. Aeration of the nappe usually requires the construction of air passages leading to the space beneath the nappe. The sidewalls of the channel should be smooth and parallel and should extend downstream beyond the overfall above the level of the crest. Weirs of a length exceeding approximately twenty times the head (excepting in cases where the velocity of approach is extremely low); or weirs of moderate crest length having high velocities of approach; or those in which the velocity of approach is irregularly distributed, or in which the len[illegible]g channel is subject to the action of the wind, shall either be subdivided into a number of sections or the head shall be observed not only at both sides but also at intermediate points across the channel of approach.

166 The head on a weir must be carefully measured. A small percentage error in head measurement causes approximately $1^1/_2$ times that error in calculated discharge. Considerable errors in the measured head may be made by careless methods of referring the crest level to the head gage scale, and by assuming that a non-level crest is level without knowing the average level. The mean level of the water surface must be measured, not the crests of the small waves or surges existing in all flowing water.

CURRENT METER

167 Ordinarily, the current meter is provided with a mechanism which completes an electric circuit at each revolution, or at a given number of revolutions of the current meter wheel. By means of wires connecting the meter to batteries and buzzer or other indicating device, the observer is enabled to determine the rate at which the wheel revolves. Some current meters are arranged with mechanical recording devices. Current meters may be suspended from a cable or attached to a rod. In the former case they are generally provided with electrical recording devices and these are better suited for large streams where observations are taken from a boat or cable station or other more or less insecure positions. Meters attached to rods are better suited for work in small streams or canals where observations are taken from a bridge.

168 The measurement of flow of water by means of a current meter cannot be regarded as an extremely accurate method on account of the difficulty of duplicating the conditions under which the instrument is calibrated with the conditions under which it is used. A meter properly calibrated in straight line flow or in still water will give accurate determinations when used at the same velocities in a stream in which the flow is free from whirls or eddies, but strictly speaking such conditions are never attained in streams. Furthermore, the degree of disturbance cannot be observed or determined. The best that can be done is to calibrate the meter for straight line flow and to use it only under conditions where reasonably straight and smooth flow may be expected to occur.

169 The meter should be calibrated before using on a test and also after using. If the current meter is to be used suspended from a cable or attached to a rod, it must be calibrated similarly.

170 The hydraulic section on which the measurements are to be taken is selected primarily with regard to flowage conditions. The bottom and sides should be smooth and the section uniform for a sufficient distance both up and down stream to insure a smooth flow and avoid turbulence. Accurate soundings should be taken at close enough intervals to insure an accurate determination of cross-sections. When soundings are made in a current, corrections should be made for the deflection of the sounding cable. Where meters suspended from flexible cables are to be used, it is desirable to take the soundings with cables giving the same deflections as the meter cables, insuring the determination of the cross-section in the same plane as the meter readings. All soundings should be plotted for the same mean stage. The hydraulic section should then be laid out to some convenient scale and divided into sections or panels.

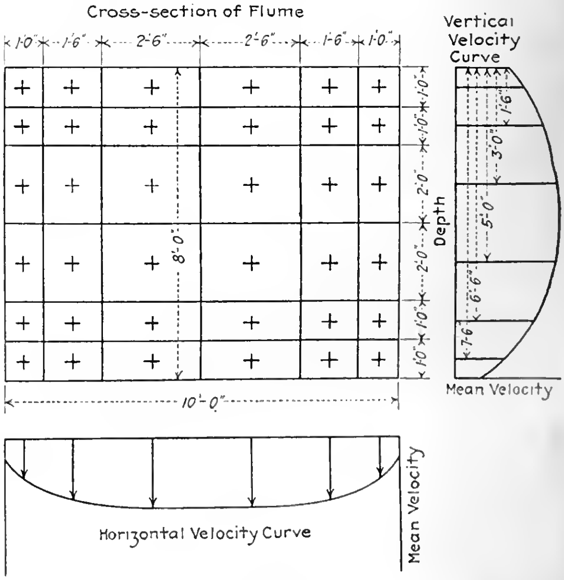

FIG. 108

INDIVIDUAL UNIT TESTS

171 After the cross-section is accurately determined, it should be laid off in vertical sections and enough point stations located on the center line of each section to enable a consistent vertical curve to be plotted. The point method should be used, holding the meter at each predetermined point a sufficient time to allow the varying velocities of a cycle at that point to register. Under uniform velocity conditions the duration of time at each point should be not less than one minute. The top station should be just under the water surface and the lower station as near the bottom as the meter will operate. The depth of water should be accurately recorded during the test. After the vertical velocities are plotted and the areas planimetered in order to get the mean velocity, a horizontal velocity curve should be plotted from the mean vertical values.

172 By continuing the curves to the sides and bottom of the section, the entire area is considered in the determination of the quantity. See Fig. 108.

COMPLETE PLANT TESTS

173 When a section is large enough, or the possible distribution of the load is likely to affect the distribution of the flow, the section should be divided into two or more main panels, and these again divided into subpanels. An index point is then selected for each panel, preferably at the point of maximum velocity, which occurs usually at about 0.4 depth. In order to avoid the necessity of making a complete traverse of the section for each loading, the observations are made comparable by using two or

three meters. It is preferable to use three meters, one at the index point of each panel, while the second one is being used to make a traverse of the panel, the third meter being used as a master index meter fixed at one point in the stream. If only two meters are available, one should be fixed at the index point of one of the panels while the other is used to make the traverses of the various panels. All meter readings are to be reduced to percentages of the simultaneous index reading. Simultaneous observations should be taken of the time, time intervals, meter depths, (proportionate depths if water level varies), meter readings, and section gage readings, and notes taken from time to time regarding all matters pertaining to the work. Vertical velocity curves are plotted these being located on vertical center lines of the sub-panels. The points of determination should be the sub-surface and bottom and enough intermediate points at even proportions of the depth to insure a proper determination of the vertical velocity curve. The sub-surface depth in each case should be just sufficient to insure a proper submerging of the meter; the bottom depth in each case being just enough above the bottom to allow the meter to clear properly. One of the points selected should be at 0.4 of the depth to correspond to the index reading. The meters in each panel should be interchanged from time to time and inspected frequently. All velocity observations of the vertical curves are first reduced by dividing each by the simultaneously determined velocity at the index in the same panel, and expressing the quotient as a percentage. The average of the accepted percentages of each point is computed, and divided by the average for the 0.4 depth point of the same vertical. A plot for each curve is constructed with percentage depths as ordinates and percentage velocities as abscissas. A smooth curve is drawn through the points. The coefficient of the curve is derived by measuring the area, this area being divided by the proportionate depth gives the mean abscissa of the curve, and the mean abscissa divided by 100 (the percentage at 0.4 depth point), gives the vertical velocity coefficient. A transverse curve is then plotted, using the 0.4 depth points on the verticals as points on the transverse curve. As in the case of the vertical curves, the first step in the transverse curve reductions is to divide the observed velocity at each point by simultaneously observed velocity at the index in the same panel. The percentages are then tabulated, arithmetic means are taken of all the observations at each point, and a curve drawn through all of the resulting points. In each sub-panel the mean percentage ordinate of the transverse curve is determined, the results giving the transverse coefficient in terms of 100 per cent at the index. The sub-panel areas at the mean water elevation are determined and expressed as percentages of the entire area. The transverse and vertical coefficients in each sub-panel are weighted according to the relation which the area of the sub-panel bears to the whole panel area. Accordingly, the general coefficient for the index is obtained by multiplying for each sub-panel the transverse coefficient by the vertical coefficient and by the percentage area, adding the results and dividing by 100.

174 The elevation of the water surface should be continuously observed during a run of current-meter measurements, preferably by direct measurements down to the surface from fixed points on a bridge or by means of stilling boxes. If the supporting rods for the meters are in the same cross-sectional plane as the meters, the area of the rods should be deducted from the wetted area of the channel in calculating the quantity. The meter should preferably be supported by rods placed a sufficient distance behind them to avoid any obstructive effect. When a heavy mast or supporting frame is used, it should be designed to offer a minimum disturbance, and should be located several feet downstream from the meter.

175 Velocities below 0.5 ft. per second cannot be accurately measured. A Venturi meter flume of plank can sometimes be built into a channel to increase the velocity, the throat making an ideal current meter station.

Special Methods for Measuring Water

176 *Traveling Screen.* The traveling screen, also called the "diaphragm method" of measuring water, provides for the determination of the mean velocity from a single observation. This method requires elaborate preparations, but when the apparatus is once installed it may be used for as many observations as desired. It is adapted only to open channels of very regular cross-section. A very light canvas screen, varnished to insure imperviousness, is suspended by a stiff frame from a wheeled carriage mounted on tracks along the edges of the channels. The rate of movement of the screen must necessarily be the mean velocity of the water. A small crack about 0.5 inch should be provided between the screen and the sides and bottom of the channel to insure freedom of movement. Provision must be made for accurately observing the velocity of the screen, preferably by electric contacts and chronograph. The length of run of the screen should be sufficiently in excess of the portion used for measurement to provide ample space for starting and stopping the screen, so as to insure uniform conditions over the measured portion of the run. In determining the discharge, the velocity of the screen is to be multiplied by the average area of stream cross-section of the portion of the channel traversed. The variation of the level in the flume should be observed during the course of the run and the average elevation used in determining the area. It is possible to measure the flow of water within 1 per cent by this method under the most favorable circumstances.

177 *Volumetric or Bulk Method.* Volumetric methods of measuring water, which require the determination of the volume of water flowing in a given time by means of measuring vessels are limited to laboratory use and are outside of the scope of this code.

178 The bulk method is applicable only when there is available a reservoir of regular form, the volume of which, up to various water levels, may be accurately measured. In the case of a test on a turbine, the power must be measured continuously and the average obtained. It must be possible to shut off completely all inflow to the reservoir. The tightness of the gates and reservoir walls must be tested by closing all gates and observing over a time of several hours the rate of rise or fall of water level in the reservoir throughout the full range of variation of level which will be used in the turbine test. At the same time any leakage through the turbine head gates is to be measured. The surface elevation in the reservoir is not to be so affected by velocity or wind effects as to cause local variations in level of more than 5 per cent, of the total draw-down used in the turbine tests. This variation is to be observed by gages distributed over the whole reservoir, which are to be read simultaneously at short intervals through the test.

179 *Color Method.* When the water to be measured passes through a conduit suited to the purpose, the color method of quantity determination may be used. A solution or paste of coloring matter, commonly one of the aniline dyes, is injected into the conduit and the time required for it to pass through a known distance observed. This distance should be at least 200 times the mean velocity in feet per second. The coloring matter may be introduced as a paste at the intake to the conduit or it can be injected by a force pump or gun into the conduit at any convenient point. The particles of coloring matter will usually remain within a section having a length equal to 10 per cent of the distance traveled. Time observations should be made at the instant the coloring matter is introduced and at the first and last appearance of the coloring matter at the second point of observation. The mean rate of flow will be the volume included between the two points of observation divided by the mean of the two time intervals. If the conduit is not of uniform area it must be of sufficiently regular form to permit its volume to be accurately determined between the two stations.

180 This method may be very accurate if proper care is used in introducing the coloring matter to avoid any leakage of it into the water prior to the stated starting time, and to insure a prompt entraining of the entire amount by the body of the stream.

181 *Brine Velocity Method.* This method of measuring water is a modification of the color method, and is carried out by introducing in place of the coloring matter a concentrated salt brine or other chemical that is a good conductor of electricity. The time of passage of the brine is detected by the variation in electrical resistance indicated by a galvanometer which is connected to batteries and to an electrical circuit having poles inserted into the conduit at measured observation points. The galvanometer will show a stronger current while the prims containing the brine is passing the poles. This method has the advantage over the color method in that is it not necessary to see the water. The points of observation can be at any point in the conduit, as it will only be necessary to drill small holes in the pipe to insert the poles.

182 Experimental work now in progress indicates that this method of measuring water is capable of giving very accurate results (probably within 0.5 per cent of the true value) when properly used. (These experiments are being conducted by Prof. Chas. M. Allen, Worcester Polytechnic Institute.) Such tests as have been made lead to the conclusion that the time of maximum conductivity should be used; i.e., the time between the introduction of the brine and the time when maximum conductivity is indicated at the downstream station. It has also been found that it is possible and desirable to combine the two electrodes into a single fixture which can be inserted through one hole in the wall when used with closed conduits.

183 *Pressure—Time Method.* This method of determining the velocity of flow in a closed conduit is one recently invented by Norman R. Gibson, in which the changes of pressure in the conduit when closing a valve or the turbine gates are recorded by means of special apparatus. The record thus obtained results in a diagram called the "pressure time diagram" which, when properly interpreted, is a measure of the mean velocity that existed in the conduit prior to the interruption of flow. This method depends upon the principle that impulse is equal to momentum. A complete description of this method appears in Proceedings of the American Society of Civil Engineers, April, 1919, pages 173–206 and in Mechanical Engineering, April, 1921, pages 247–248.

Head-Measuring and Pressure-Measuring Apparatus

184 *Measuring Stick.* A good method for determining the elevation of the surface of flowing water is by direct observation. For surface determination in channels, a horizontal bar with its upper edge at a fixed or determined elevation, or a stretched wire, should extend across the race-way. The perpendicular distance from the upper edge of the bar or wire to the water surface should be measured at each station by means of a measuring stick with a graduated scale on its side. The graduations should preferably be marked so that the elevation of the water surface can be directly read off opposite the upper edge of the horizontal bar or wire at the instant the bottom of the measuring stick touches the surface of the water. An access bridge should be provided to facilitate measurements from the bar or wire.

185 *Float Gage.* For cases of great range of levels, a graduated tape, attached to a float and passing over a pulley, and provided with a suitable counterweight, makes a sensitive indicator.

186 For cases of small range of level, a graduated rod is attached to the float.

187 For flowing water the float must always be placed in a stilling box. (See Par. 189.)

188 *Hook Gage.* The hook gage consists of a sharp pointed hook attached to the lower end of a graduated rod, equipped with a vernier and sliding vertically in fixed supports. To take a reading on a water surface, the point of the hook is lowered below the surface and then slowly raised by a screw at the top of the instrument. Just before the point of the hook pierces the skin of the water surface a pimple is seen to rise above it; the vernier should be immediately read.

189 *Stilling Box.* Stilling boxes for use in connection with float, hook and other gages must be so constructed that they will not cause systematic

errors resulting from velocity effects and should, whenever possible, be open to full view of the observer, so that no errors due to sticking of the float may be introduced. For flowing water in open channels, the stilling box is placed outside the channel and communication is made by a small pipe, the end of which must be flush with the inside wall.

190 *Pressure Gage.* These gages are liable to error after having been in use for some time, especially when used with high or suddenly varying pressures, and should be frequently calibrated. Great care must be exercised in connecting dial pressure gages so that all air in the connection and the gage coil can be removed. There must be a point in the connecting pipe near the gage which is higher than the gage, and a petcock must be located at this point so that any entrained air may be removed. The gage must be so connected that it can be turned upside down while water is filling the connection, thus allowing the air in the gage coil to escape to the high point. The pressure observed then is that at the center of the gage dial.

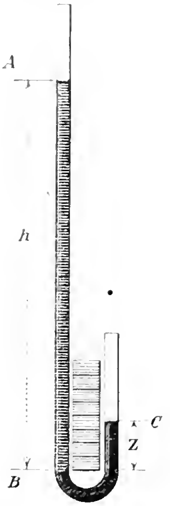

Fig. 109 Simple Manometer

191 *Manometers.* The open liquid column manometer furnishes the most direct means of measuring the pressure head of water. Fig. 109 shows the principle of construction of such a gage. A bent glass tube ABC, with both ends open has mercury, or some other liquid heavier than water in its lower portion, the water column of a height h being balanced by the mercury or other liquid of height Z. If the atmospheric pressure at A and C are the same, then h (in feet of water) equals $s \times Z$, where s is the specific gravity of the indicating liquid. Obviously, water cannot be used as an indicating liquid because of the pressure pipes being filled with the same liquid. For measuring pressured heads between 1 and 50 feet of water, mercury should be used in the manometer. For measuring pressure heads less than 1 ft. of water, carbon tetrachloride or certain oils having specific gravities greater than 1.0 can be used instead of mercury to magnify the indication of the manometer. It is possible to get still further magnification by inclining the manometer or by using other magnifying devices such as gasometer gages, differential manometers using two liquids with different specific gravities, etc.

192 The manometer can be used to measure differential pressures by connecting the two ends of the bent tube to the two pressure pipes leading to the conduit or instrument containing the liquid under test.

193 Fig. 110 (a) shows a manometer used in an upright position and filled with mercury or some other liquid heavier than water. When filled with mercury a manometer so set up is suitable for measuring differential pressures between 1 and 50 ft. of water, which correspond approximately with 1 inch and 48 inches of mercury, respectively. For measuring differential pressures below 1 ft. of water the manometer should contain carbon tetrachloride (specific gravity 1.3 to 1.6) or some oil heavier than water in order to magnify the indications. Still further magnification can be obtained by inclining the gage or by using a gasometer gage. Because of the water above the indicating liquid in the manometer tubes the differential head h (in feet of water) equals $h' \times x(s-1.0)$, where h' is the measured head of the indicating liquid and s is its specific gravity.

194 Fig. 110 (b) shows an inverted manometer which when connected at D with a partial vacuum or a pressure above atmospheric, as the case may require, provides means for bringing the surface of the water in the pressure pipes or manometer within the glass tubes where the differential pressure can be read directly in feet or inches of water. In some cases it is desirable to magnify the indication by using kerosene or some other oil lighter than water and that will not mix with it, in the top of the manometer instead of air. The differential pressure head h (in feet of water) equals $h'(s-S)$, where h' is the measured head of the indicating liquid, s is its specific gravity, and S is the specific gravity of the material above the water in the top of the manometer.

SPEED MEASURING APPARATUS

195 *Hand Revolution Counter.* The hand revolution counter or speed counter consists of a small shaft pointed at one end and geared to operate the counting device. If handled carefully and well made it is a reliable type of instrument, particularly for speeds from 200 to 2000 r.p.m. As there is a possibility of introducing considerable error in making the measurement by not accurately gaging the time that the counter tip is put in contact with and breaks contact with the end of the shaft under test, it is desirable to make the period of contact between the counter and the shaft two or three minutes instead of for only a few seconds. If a $^1/_5$ second stop watch is used to time the period of contact and there is an error of only one scale division on the watch made in measuring the period of contact the error in the observed r.p.m. will be as follows:

Period of contact	Error in r.p.m. (per cent)
15 sec.	±1.33
30 sec.	±0.67
1 min.	±0.33
2 min.	±0.17
3 min.	±0.11

To prevent slipping of the point at high speeds, a rubber tip is sometimes used. If the tip is not true or the instrument is so held as to allow the axis of the counter shaft and the axis of the shaft being tested to be out of alignment there will be an appreciable error in the speed measurement, as the rubber tip under such conditions becomes a reducing gear of unknown and variable ratio.

196 *Revolution Recorder.* This instrument consists of a series of gears operating a set of dials indicating, by successive digits, the total number of revolutions. For accurate work this instrument should be connected to the rotating shaft by means of a positive clutch or equivalent device which will prevent slip. This form of instrument is not suited for speeds much over 250 r.p.m.

197 *Tachometer.* A tachometer indicates the instantaneous speed of a rotating shaft. If it is driven at the proper instrument speed through a set of gearing between the shaft under test and the instrument, it is suitable for measuring speeds from 6 to several thousand r.p.m. The use of gearing instead of pulleys and belts eliminates slip which may be a source of considerable error with belt driven tachometers. The instrument should be calibrated in any case.

Transactions of the International Engineering Congress, 1915, Now Available

The transactions of the International Engineering Congress which was held in San Francisco simultaneously with the Exposition celebrating the opening of the Panama Canal are now available through the Engineering Societies' Library. These papers form a valuable contribution to any collection of modern engineering literature, since the congress both in scope and in character, was truly international.

The entire set of these transactions consists of eleven bound volumes, having for their subjects, The Panama Canal, Waterways and Irrigation, Municipal Engineering, Railway Engineering, Materials of Engineering Construction, Mechanical Engineering, Electrical Engineering and Hydroelectric Power Development, Mining Engineering Metallurgy, Naval Architecture and Marine Engineering, and Miscellany. It is accompanied by an index volume which gives an historical and statistical account of the congress, abstracts of all the papers which were presented and a very usable table of contents and author index. With the exception of the volume on the Panama Canal the treatment given each subject has been in the nature of a broad survey with some special reference to important lines of engineering advance. The papers are accompanied by a bibliography of the literature of each subject so that the reader can extend his research into any one of the topics treated.

Only a few complete sets are left but the library has quite a large number of some of the individual volumes and papers which it will gladly supply to those who wish to purchase them.

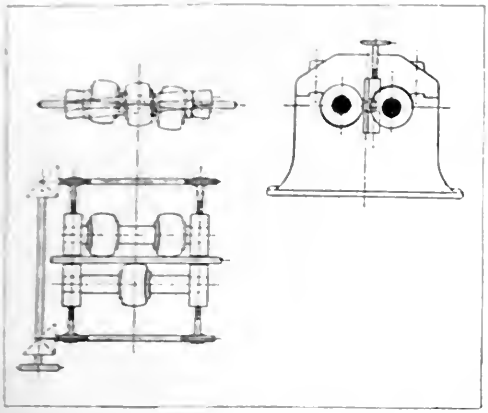
SURVEY OF ENGINEERING PROGRESS

A Review of Attainment in Mechanical Engineering and Related Fields

Friemel Cross-Rolling Mills

THE Friemel mills are designed for use on round iron, solid or hollow, where particularly high demands are made concerning the appearance and accuracy of measurement, and where a cross-rolling operation is effected after the main rolling process is finished. The Friemel cross-rolling mills are based on the same principle of operation as straightening machines, but differ from such cross-rolling mills as the Mannesmann inasmuch as the rolls are arranged not askew, but in parallel planes inclined to each other at certain angles determined by experiment.

The Friemel cross-rolling mills are chiefly used in the manufacture of tubes. The general effect of the machine is considerably enhanced by dividing one of the two rolls into two parts working on the same shaft, and then arranging the counter roll to fit into the gap between the two parts of the first roll (Figs. 1 to 3). With this arrangement of the rolls the material passing through the machine is forced to rotate around its own axis, and its exterior surface is subjected to a powerful treatment between the rolls.



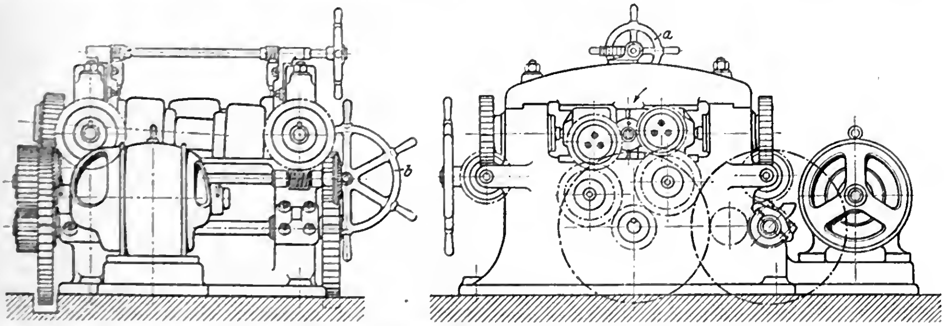
Figs. 1 to 3 Arrangement of Rolls in a Friemel Cross-Rolling Mill

It is claimed that the Friemel type of machine not only straightens the material but simultaneously unifies its diameter, and is therefore particularly suitable for finishing-off material intended to be worked later on turret lathes or automatic lathes. As the diameter of the entire piece is very uniform, no trouble is experienced afterwards in using conical grips or collets in machine tools.

Figs. 4 and 5 show a simple cross-rolling mill of the Friemel type. The machine has a powerful cast-iron frame, fitted with two guides for blocks containing the bearings of the rolls. On top the guides are covered over by strong lids, and between them the frame is designed in the shape of a trough, filled with water or oil as far as is necessary to let the rolls dip into the liquid. The blocks containing the bearings can be adjusted by means of screw-threaded spindles, particular care being taken in the design to make the blocks always move evenly toward the center of the machine, thus ensuring that the rod under treatment will never diverge from the exact center line of the machine in passing through it. The rolls must be adjusted in such a way as to exert a powerful pressure upon the rod which is being straightened.

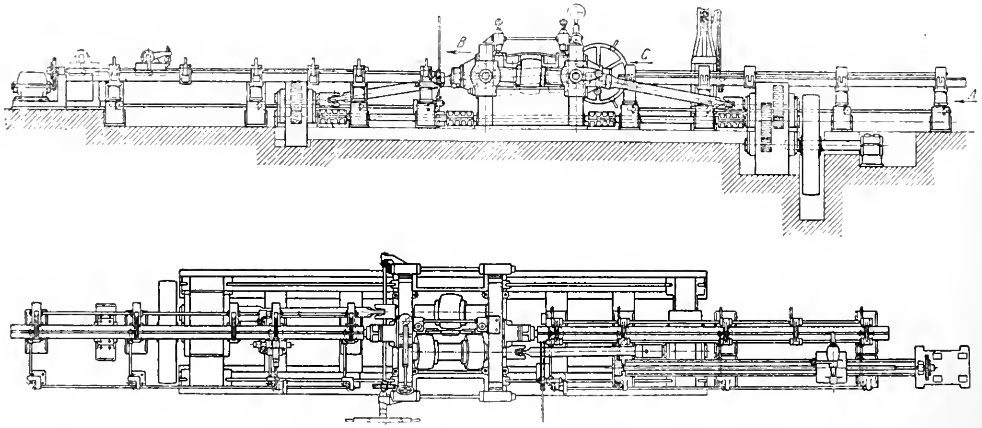
Between the rolls, the material to be straightened is guided in so-called polishing guides of iron, gunmetal, or wood, depending upon the kind of metal treated, as well as the desired exterior appearance of the finished rod. With the machine under discussion these polishing guides can be adjusted with absolute accuracy with respect to the center of the machine, in a direction vertical to the plane in which the rolls move when being adjusted. The working ledges of these guides are arranged to permit of easy exchanging. Both adjustments are effected by hand by means of worm wheels and threaded spindles. The two rolls, arranged on a joint shaft, can be shifted about on the latter, thus permitting adapting the distance between them to the thickness of the material passing through. The cross-rolling mill described is provided with individual electric drive through an intermediate spur-wheel gear. In view of the whole nature of the design, it was impossible to avoid using bevel spur-wheels for the gear. As the spur-wheel gear, forming a complete unit with the rolling mill, does not work very efficiently owing to the unsatisfactory conditions prevailing at the bearings, it has become more and more usual to employ an arrangement involving the use of separate spindle housings and intermediate shafts with ball-and-socket joints. Of course, the initial cost of this arrangement is somewhat higher, but this is soon compensated by the resulting reduction in wear and tear.

In addition to the actual Friemel cross-rolling mill, straightening plants of this kind also need guiding troughs. For small machines these simply consist of a strong angle or V-section, the latter being adjusted for height by means of threaded spindles; under ordinary circumstances this arrangement will fully serve its purpose. However, as a good deal of time is wasted in adjusting the various spindles separately, the troughs are frequently equipped with a joint drive for adjusting the spindles. To this end the nuts of the



Figs. 4 and 5 Friemel Cross-Rolling Mill for Round Iron Sections and Tubes

spindles are fitted in worm wheels, the driving worms themselves on the other hand all being arranged on a joint shaft. A further improvement consists in the trough being provided with lids which can be turned up, an arrangement to be commended especially for the feeding trough. These lids are intended to prevent the rod from jumping out of the trough. Experience has proved that long rods particularly have a great tendency to behave in this way owing to their passing through the machine unstraightened, while simultaneously rotating at a comparatively high speed. This leads to the rods knocking and lashing about wildly.



Figs. 6 and 7 Heavy Friemel Cross-Rolling Mill for Straightening Superfine Steel up to 150 mm. Diameter

To handle the heavy rods in large machines, it is well to equip the delivery trough with a transferring appliance. The latter simply consists of levers cutting into the trough, and arranged to be swung out of the trough together with the rod. The operation of the levers can either be made by hand or mechanically, i.e., electrically or hydraulically, depending on the size of the plant and the output. With machines designed for straightening hot and heavy rods, an inserting device located alongside the feeding trough will facilitate operations materially. Such an inserting device consists of a sliding table on some kind of a guide, motion being imparted to it by a threaded spindle with electric drive. A bracket fastened to the slide (with a set of springs between) extends into the trough, where it presses the rod forward and into the machine.

View A

View B

View C

Figs. 8 to 10 Detail Views of Parts of Figs. 6 and 7

Figs. 6 and 7 illustrate a Friemel machine of particularly powerful construction, designed for straightening highest-grade steel sections in the hot state, the machine being capable of dealing with sections up to diameter of 150 mm. (6 in.). The guiding troughs have a length of 6 m. (20 ft.) and the machine is driven by pinions and coupling pinions. A belt drive and jockey pulley are inserted between the driving gear proper and the motor. Most of the other special contrivances mentioned previously will also be found on this machine; but it has a common height adjustment for the spindles, raising and lowering the guiding troughs, turn-up lids on the troughs, as well as an inserting device.

The biggest Friemel cross-rolling mill hitherto built is capable of straightening tubes of ball-bearing steel in the cold state with an outside diameter up to 270 mm. (10.10 in.) and an internal diameter of 200 mm. (8 in.). This machine, which incidentally already possesses huge dimensions, was also provided with pinion drive and mechanical adjustment of the rolls. Short Abstracts of the Month

AERONAUTICS

Goodyear Gear-Driven Airship. One of the important features of the new military airship built for the U. S. Army by the Goodyear Tire and Rubber Company is its gear drive from engine to propeller. In the past considerable difficulties have been experienced with such transmissions. There was heating up of the oil; excessive vibrations due to torsional reactions; and the tendency of the transmission to get out of step with the motors, resulting in excessive gear noise.

In designing the Goodyear transmission, it was decided to make the entire assembly one integral unit wherein the clutches, couplings, gears, shafts and propeller gear housing would be built together in the most direct manner. The transmission was designed with spiral bevel gears in which considerable experience was available in view of their popular use in the automobile industry. In the preliminary test run on a dynamometer it was found that there was an entire absence of gear hum and very little heating. To get an absolute measurement of efficiency of this unit, a large wooden stand was constructed upon which were mounted two Aero-marine 135-hp. motors with two clutches connected thereto, and additional elements to take up misalignment. A test load of 1000 lb. was hung on the propeller tip with the deflection of only 0.098. This was done to obtain an assurance that a propeller which weighs only 80 lb. would not cause any excessive bending movement on the transmission tube. (The tubes were cast of aluminum and heat treated.)

The transmission driven airship permits the motors to be placed within the car, thereby making them very accessible. In the case of non-rigid and semi-rigid airships, it permits Sirocco type fans to be attached directly to the motors, thereby permitting the elimination of scoops, which offer considerable resistance and add a large amount of weight. It permits any mechanical adjustments to the motors, and in the case of the above unit, a complete cylinder head could be removed while in flight. As the heating up in any transmission is a direct indication of power losses, due to the entire absence of this trouble in the Goodyear type transmission, it is conservatively estimated that an efficiency of 98 per cent is obtained

The fact that the propellers are 11 ft. in diameter, and have a pitch of 10 ft. 6 in., and also the reduction of head resistance and the absence of protruding members, should presage a considerable gain in the speed of the unit.

In view of the unit arrangement of the transmission, a reverse gear was inserted, permitting the propellers to be reversed without difficulty. The tractor-type propellers were so arranged as to permit the edge of the tube to be stream-lined. The radiators are to be set on bosses located on the tube, thereby placing them directly in the slip stream. The tractor type propellers offer the advantage of safety by keeping all these mechanical parts to the rear of the blade.

The characteristics of the unit are as follows:

Speed, m.p.h.	60
Rate of climb, ft. per min.	1000

While this unit is an experimental airship, it has proven, a decided improvement in the non-rigid type of airship, even with the enclosed car, transmission, reverse feature and two additional passengers. Ships of this design could be constructed up to 300,000 cu. ft. capacity without the slightest difficulty. The entire design adapts itself to the insertion of a rigid keel, which would permit ships up to at least 1,000,000 cu. ft. to be built, with a saving in structural weights and increased useful lift. (*Aerial Age Weekly*, vol. 14, no. 20, Jan. 23, 1922, pp. 473–474 and 479, 2 figs., *d*)

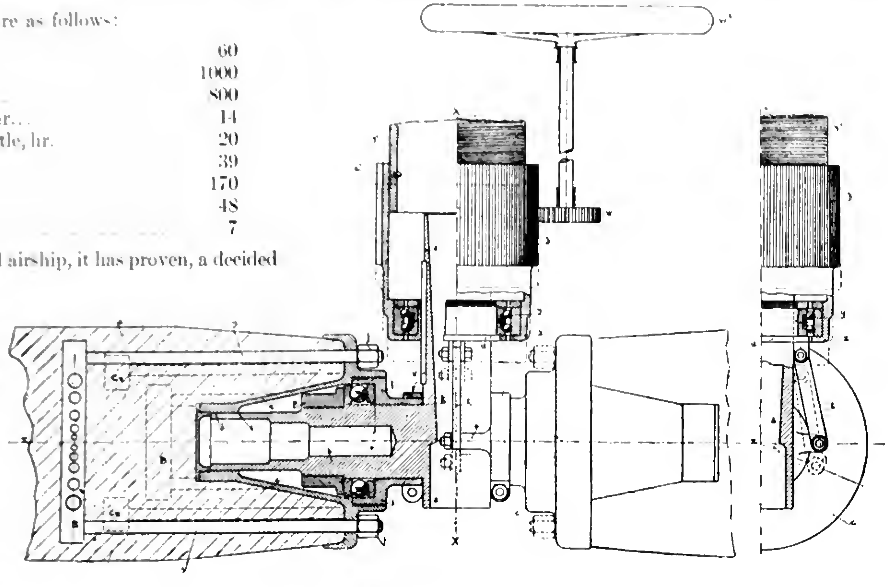

Fig. 1 Levasseur Variable-Pitch Propeller

Variable-Pitch Propeller

Levasseur Variable-Pitch Propeller. At the 1921 Aeronautical Exhibition in Paris, there was shown the variable-pitch propeller designed by Pierre Levasseur who has been identified with the aeronautical industry practically since its inception as an inventor and builder.

In the Levasseur variable-pitch propeller, the wooden hub is in compression from the inside instead of being held in compression from the outside.

The general view of the Levasseur propeller is shown in Fig. 1. The propeller blades are connected by anchor bolts, with castings mounted on lateral hollow shafts in the propeller hub. The pitch variation is carried out by displacement of these mountings on their respective shafts. The centrifugal forces are taken up by the ball bearing shown in the drawings.

Tests carried out in the laboratory of the School of Arts and Manufactures and at the Chalais-Meudon Field have shown that the new propeller gave satisfaction. The weight, at least in the first types, was somewhat greater than of a constant-pitch propeller, but a reduction is expected from an improvement in the design and material of the metal parts. A ten-hour test of the propeller run by a motor has shown that variations of pitch could be carried out under all conditions of operation without requiring any excessive muscular effort on the part of the pilot. It is pointed out that the development of the variable-pitch propeller will play an important part in the wider use of superchargers. (In this connection, attention may be called to the variable-pitch propeller developed at McCook Field, Dayton, Ohio, by the engineers of the Air Service of the United States Army and described in McCook Field and American Aeronautics, *Mechanical Engineering*, August, 1920, p. 442.) (*L'Aerophile*, vol. 29, nos. 23–24, Dec. 1–15, 1921, pp. 18–19, 2 figs., *dA*)

ENGINEERING MATERIALS (See also Machine Shop and Foundry)

A New Heat Resisting Alloy

Calite, New Heat-Resisting Alloy. It is stated that calite is a new alloy that melts at 2777 deg. fahr., softens at 2500 deg., and is safe to use at temperatures not exceeding 2200 deg. though it has been used at somewhat higher temperatures without bad results. Its specific heat is 0.123, thermal conductivity one-quarter that of iron, and elastic limit 36,800 lb. per sq. in.

Calite containers are used for carbonizing, annealing, heat treating and for the holding of molten lead, salts and cyanides.

From other sources information is available that calite readily casts into various shapes and can be ground, but is not suitable for machining. It should not be used in the presence of molten aluminum. No reliable data as to its composition are available. (*Coal Age*, vol. 21, no. 5, Feb. 2, 1922, p. 209, *d*)

High-Carbon Seamless Steel Tubing, W. W. Hackett. Data on experiments made on aeroplane tubing during the war. It was found then that excellent results could be obtained by using 0.5 per cent carbon—steel tubing, giving in the bright or glue state a yield point of 40 to 45 tons per sq. in., and an ultimate stress of 45 to 50 tons per sq. in. In the motor trade there was a disinclination to use these high-carbon steel tubes, which it was thought would necessarily be brittle. No extra care had been used in heat treatment, but the results of hundreds of tests carried out showed that 0.3 per cent carbon was always better than 0.15 per cent, and 0.5 invariably superior to 0.3 per cent. Details were given of a number of these tests. In one series 20-gage tubing made of 0.54 per cent carbon steel had practically as long a life under the same weight and shocks as 17-gage tubing manufactured of 0.338 per cent carbon steel. Figures were given showing the greater strength of high-carbon than of medium- and low-carbon steels. One experiment showed that a 20-gage high-carbon steel was practically as strong as a 15-gage low-carbon steel, though only half as thick. This was attributed to the fact that after undergoing the brazing process the elastic limit of a 0.5 per cent carbon steel was about twice as high as that of a 0.15 per cent carbon steel at the brazed joint, and consequently the high-carbon steel was able to stand much more stress than the low-carbon. It was also concluded that the high-carbon quality had twice the life of a low-carbon when subjected to the same fatigue. (Paper read before the Joint Meeting of the Institution of Automobile Engineers and the Birm-

ingham Metallurgical Society. Abstracted through *Iron and Coal Trades Review*, vol. 104, no. 2811, Jan. 13, 1922, p. 42, *et*)

Manufacture and Properties of Steel Plates Containing Zirconium and Other Elements, Geo. K. Burgess and R. W. Woodward. This investigation originated from the need of the Ordnance Departments of the Army and Navy for information regarding the effects on the ballistic properties of light armor plate, of certain chemical elements, such as zirconium.

A joint program was outlined according to which the Bureau of Mines was to produce and analyze ingots of the desired compositions; the Bureau of Standards to manufacture and heat-treat plates, to carry out physical tests, micro-examinations and chemical analyses, and develop methods of chemical analysis, when needed, for the more unusual elements in steel and in the presence of each other; and the Navy Department to carry out the ballistic tests.

Although the results of the ballistic tests are not available for publication, an account of the mechanical properties and tests of this series of somewhat unusual steels was considered worthy of publication. These results may be summarized as follows:

About 193 heats of steel containing in various combinations the following principal variable elements; carbon, silicon, nickel, aluminum, titanium, zirconium, cerium, boron, copper, cobalt, uranium, molybdenum, chromium and tungsten, have been studied.

None of the steels presented any difficulties in rolling into plate except those containing boron.

The usual mechanical properties and impact tests were carried out on all the steels. It is shown that steel containing 0.40 to 0.50 per cent carbon, 1.00 to 1.50 per cent silicon, 3.00 to 3.25 per cent nickel, and 0.60 to 0.80 manganese, and deoxidized with a simple deoxidizer such as aluminum, can be produced having a tensile strength of approximately 300,000 lb. per sq. in. and with excellent ductility and toughness. This type of steel is recommended for a structural material.

Although the same high properties are obtained in steels of the above composition with the aid of additional elements, it does not appear necessary to resort to such additions of expensive alloying elements.

Zirconium, like titanium and aluminum, acts primarily as a scavenger, and when it is not removed as part of the slag it remains in the steel in the form of square bright yellow inclusions not directly visible at magnifications lower than 500 diameter. It is not considered that these inclusions can be very beneficial, and if they are segregated and rolled out into thin plate-like streaks they may be deterimental, especially in armor plate.

Of the other elements that are regarded as special alloying additions, chromium, tungsten, vanadium and molybdenum go into solution and produce a martensitic pattern in the air-cooled specimens. Cerium and uranium act in a similar manner but also show characteristic inclusions. Copper goes into solution but a larger amount is required to produce a martensitic-pattern in the air-cooled samples than for the others. Boron forms a complex eutectic, probably that of an iron-carbon-baron compound with iron. This eutectic is fusible at the temperatures ordinarily used in rolling, but at slightly lower temperatures steel containing boron can be rolled successfully. Hot working breaks up the eutectic and spherical hard particles, similar to iron carbide globules, are formed. (Abstract of *Technologic Paper No. 207 of the Bureau of Standards, e*)

FOUNDRY

Air and Electric Molding Machine. Description of a machine in which air is used for ramming the sand in the molds, and electricity for rolling the flask and afterward drawing the pattern.

The reason advanced for retaining the air-ramming device rather than electrifying the machine entirely is that air gives a cushion shock when the table drops.

A lever at one end which can be thrown into, or out of engagement with a cam slot determines whether the table automatically rolls over in its upward or downward travel, or remains in the original position. In the ordinary routine of operation, the lever is thrown into engagement at the same time, or a few seconds before, the motor is started to raise the table. The flask is located on the table to permit of a slightly over-balanced load, and the table is rolled on its approximate center of gravity. The table swings through an arc of 180 deg. on its upward travel and the remaining 180 deg. on the down trip. The lever then is thrown out of engagement and when the motor is started again the table is raised vertical and rigid while drawing the pattern. The action is positive and instantaneous, and may be regulated to produce the very slowest speed desired when starting the pattern. Then when the pattern has been loosened it may be raised to full speed at the will of the operator. The entire operation of rolling to the table or drawing the pattern is under the control of the operator at all times and may be stopped at any point. Automatic contact points are provided at rolled three stages—where the plungers have reached the limit of their stroke either up or down and where the flask comes to rest on the transfer car. At either of these three points the power is cut off and the motor is brought to rest by a quick-acting brake operated by electricity. (*The Foundry*, vol. 50, no. 2, Jan. 15, 1922, pp. 75–76, 1 fig., *d*)

German and British Experience with Synthetic Cast Iron

Synthetic Cast Iron. By synthetic cast iron is meant material produced by recarburizing steel. His article describes in particular a series of trials made at the Rombach Works in Germany during the war. In these trials a cupola of about $37^1/_2$ in. diam. was used. It was charged with 2 tons of coke to a height of $7^3/_4$ in. above the tuyeres. After the blast was put on, more coke and 350 lb. burnt lime was charged. Then charges were put in, of 1100 lb. structural steel scrap, 200 lb. coke and 66 lb. lime, and with the first 5 tons of scrap, 900 lb. of 10 per cent ferrosilicon was charged. About three times the usual amount of slag was produced, and the slag was acid. Some runs were made without ferrosilicon but with more lime, ferrosilicon (110 lb., 75 per cent) being, however, added to the ladle when tapping.

In some of the tests the iron was too sluggish, and about one lb. of lime had to be added in each foundry ladle. In all cases it was found that the lining of the cupola was badly eaten away, the coke consumption was very high, and in addition to this, notwithstanding the high lime charge, high increase in sulphur was observed. The high coke consumption is due to the difficulty of melting low-carbon steel scrap in the cupola, and the high sulphur is due to the use of large amounts of coke.

If the coke consumption could be seriously reduced, then simultaneously all these difficulties could be removed. Liquid low-carbon metal was available from the steel works, and if the whole could be charged with molten iron the whole burden of melting would be removed, and only the carburizing remain.

On this hypothesis the following experiment was based: The first test was carried out in a pipe about $6^1/_2$ ft. long and 3 ft. 3 in. diameter, lined with one layer of ladle brick and provided with a bottom and a taphole. Before each test a fire was made, the whole pipe filled with coke, and the whole blown as hot as possible. Molten low-carbon basic Bessemer metal was then poured into the white-hot column of coke in the pipe. In order to prevent pits being formed in the coke the ladle was moved slightly during pouring, the coke thrown continuously into the stream of metal.

During the pouring, or shortly before, ferrosilicon and manganese were added. Five minutes after the filling with the 5 or 6 tons of molten metal, the taphole was opened and the metal teemed into the molds. The resultant iron was examined chemically and microscopically to ascertain whether the carbon was really combined, and not simply mechanically mixed with the iron. The results on several casts are shown in Table 1.

TABLE 1 SHOWING THE ANALYSES OF LIQUID STEEL RUN THROUGH A COLUMN OF COKE CONTAINED IN A PIPE

Si.	Mn.	Ph.	S.	C.
0.07	0.24	0.05	0.08	1.95
0.60	0.53	0.15	0.08	1.70
0.80	0.58	0.19	0.09	1.70
0.36	0.53	0.10	0.08	2.52

Similar results have been obtained with the corresponding tests carried out over a period of eight months. Only traces of mechanically included carbon have been found. The iron is extremely tough and shows a martensitic structure. The increase in phosphorus is interesting; an investigation showed this came from the slag carried over by the metal.

These experiments show that the metal must be hot and fluid, and the coke column thoroughly heated. Then there is no danger of the metal solidifying inside the coke column.

From the experience gained, a furnace similar to a cupola was built near the foundry-ladle track. At the charging-floor level, the furnace was equipped with a large door for charging coke on one side, and on the other side with a launder for the molten metal.

The furnace was provided with two sets of tuyeres and oil burners, through which blast could be blown for heating the coke. A receiver of about 25 tons capacity, heated with two tar-oil burners was provided. In front of the taphole lay the casting bed.

The *modus operandi* is to heat the receiver, and the hot gases ignite the coke in the shaft. As soon as the receiver and column of coke are sufficiently hot, a ladle of basic Bessemer steel is brought along and slowly poured down the launder, the charging door being kept closed. The metal runs down into the receiver, where it is mixed. Sometimes the process is carried out with the receiver taphole open so that the metal simply flows through it, but even this gives a uniform metal, the difference in carbon between the first and last cast being only 0.20 per cent. As soon as the metal is cast the shaft is refilled, and the furnace prepared for the next cast. Metal made in this way contains usually 2.6 to 2.8 per cent carbon, and corresponds to the so-called low-carbon special iron. The great toughness of this material is due to the metal being carburized at comparatively low temperatures.

Comparative synthetic tests with the Rombach synthetic pig iron, produced by the above process, and with Swedish charcoal pig iron, show that as produced experimentally the Rombach iron may be used as a substitute for the Swedish iron. However, the great advantage of the Swedish iron lies in its uniformity, and whether the same uniformity can be attained in the synthetic pig iron under commercial methods of production remains to be proved. The serious drawback of the Rombach iron is its spongy and rough appearance, which has not yet been eliminated. (*The Foundry Trade Journal*, vol. 25, no. 282, Jan. 12, 1922, pp. 29–30, *e*)

In this relation, attention is called to an editorial in the same issue (p. 25) to which reference is made to other processes of synthetic-pig-iron production developed during the war, primarily in Italy and France where cheap electric power and very large amounts of steel turnings were available at a time of great shortage of pig iron. In Great Britain there was another difficulty, namely, the shortage of Swedish white pig iron, which is one of the bases of Sheffield tool-steel manufacture. For making a synthetic iron in this case a most rigid specification had to be met, namely, sulphur and phosphorus below 0.02 per cent.

The manufacture of synthetic white pig iron of Swedish quality was investigated by Victor Stobie of Dunston-on-Tyne. Realizing that the intense reduction of the sulphurs associated with the building up of the carbon content meant the establishment of powerful reducing conditions, Mr. Stobie doubted whether the most expert slagging-off of the slag from a phosphorus-free bath could be accompanied sufficiently well to prevent the phosphorus from passing the 0.02 per cent mark on the introduction of reducing conditions. He therefore constructed two 20-ton stationary electric furnaces at two levels. The primary furnace, on the higher level, was the one in which melting and the refining based on oxidizing reactions was conducted; when the metal had been refined to the usual "slagging-off period" composition of C. 0.07, Si. 0.02, P. 0.009 and S. 0.03 to 0.06 per cent, a taphole was opened and the metal allowed to run into the secondary furnace, the slag on its appearance being diverted by a Y-shaped runner. In the secondary furnace the metal met an excess of pure carbon and lime, which set up intensely reducing conditions seldom met with in workshop metallurgy. No difficulty was experienced in reducing the sulphur to well within the limit, but though the phosphorus specification of 0.02 per cent was usually met, there was the same increase in phosphorus noted by the Rombach firm. In both this and Mr. Stobie's process the phosphoric slag will contain between 20 and 35 per cent of metallic iron, while the metal with which it is associated contains an unknown but possibly very high quantity of gas. Obviously, in the cold there would be a strong differentiation in the specific gravities of the two, but at steel-making temperatures they appear to be sufficiently near one another as to be at least partially miscible. Important progress in this line of work was made in France.

FUELS AND FIRING (See also Internal-Combustion Engineering)

GAS ENGINEERING

Gas Made by Carbonizing Straw, Harry E. Roethe. Description of the experimental unit installed on the Government farms at Arlington, Va., to be used by the Bureau of Chemistry. The retort is charged with unbaled straw through two oval openings at the front end, after which covered plates are tightly clamped in place. The heat is applied to the retort from beneath by the straw or wood in the firebox. Gas begins to come off when a temperature of about 200 deg. cent. (392 deg. fahr.) is reached, with the maximum production between 500 and 600 deg. cent. (932 and 1112 deg. fahr.).

Tests have shown that straw gas gives a very good light when used in gas mantle lamps, and that its use in gas hot-plates, stoves and heaters is very satisfactory. Excellent results have been obtained with the gas as a source of power for operating stationary internal-combustion engines. In this connection the gas apparently proves most satisfactory when mixed with little air and ignited under a compression slightly greater than that found in the ordinary stationary gasoline engine.

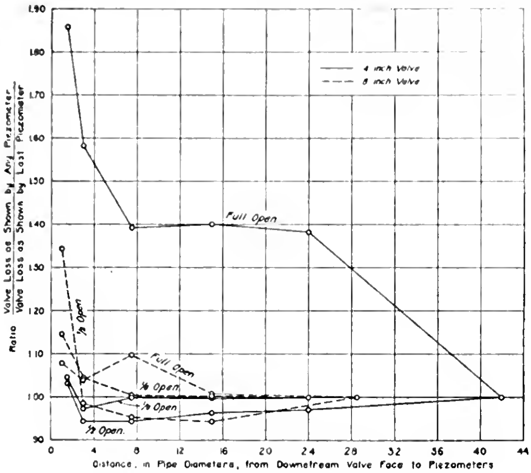

Fig. 2 Results of Experiments on Relation Between Piezometer Location and Measurement of Valve Loss

The article cites statistics which would indicate that important amounts of power could be secured from that material. (*Gas Age-Record*, vol. 49, no. 3, Jan. 21, 1922, pp. 75–76, 2 figs., *g*)

HYDRAULICS

Piezometer Location and Measurement of Valve Loss

Measurement of Valve Loss as Affected by Piezometer Location. Data of experiments carried out at the University of Wisconsin during the school year 1919–20 by M. C. Neel and C. A. Willson, thesis students, with a 4-in. and an 8-in. gate valve to determine the influence of the location of piezometer on the measurement of loss of head due to a valve.

The various piezometer openings along each main pipe were connected to a differential-gage board where the head differences could be read. The apparatus was first set up in each case without the valve in place, and the loss of head due to pipe friction only was determined. The valve was then inserted and the loss for valve and pipe determined for a number of valve openings. The results from 1/8, 1/2 and wide open conditions for both valves (4-in. and 8-in.) are shown in Fig. 2. From this it would appear that piezometers located within 3 diameters distance from the valve show in every

case an excessively large loss, and that in the region from 3 to 15 diameters downstream the disturbance of flow has caused the piezometers to register in an uncertain way.

Another figure in the original article appears to indicate that the loss is different from the normal pipe-friction loss for 40 or more diameters downstream, but when a point from 15 to 20 diameters has been passed this loss is negligible from a practical standpoint. It would also appear that there is in a section of the pipe a partial reconversion of the velocity head back into pressure head, indicated by a negative value of the loss. It is concluded that a valve causes disturbed flow in the pipeline downstream for some distance from it, and that a Piezometer opening, which is connected so as to be in this region, will be affected giving a false record of pressure within the pipe. It would appear, therefore, that the true loss is indicated only by the piezometer located at least 15 or 20 diameters of straight pipe from the valve. (*The Wisconsin Engineer*, vol. 26, no. 4, Jan., 1922, pp. 61–62, 4 figs., *e*)

INTERNAL-COMBUSTION ENGINEERING (See Railroad Engineering)

Deutz Compressorless Diesel Engine

The New Deutz Compressorless Diesel Engine, Schneider. The article is partly historical and partly descriptive. It describes and illustrates the new Deutz engine, as shown by a German patent application which has recently been vigorously and unsuccessfully contested, and also gives the previous history of the development of the art as shown by the patents to Brandis (1910 and following).

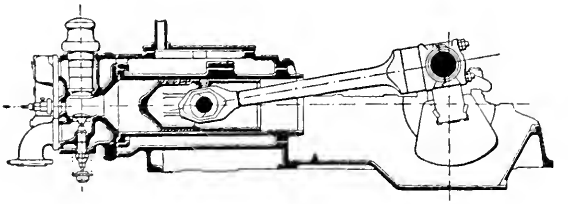

Fig. 3 Deutz Compressorless Diesel Engine

The Deutz compressorless Diesel engine is built horizontal, single-acting, 4-stroke cycle. The single-cylinder type is built in sizes of 8 to 100 hp. output and the double-cylinder for outputs from 130 to 250 hp. The basic principle of the design of this type of compressor is that an auxiliary element is used, usually placed at the end of the working cylinder and so arranged that it acts as an injector for the fuel. As shown in Fig. 3 this is effected in the following manner. A "restricted space" is provided between the cylinder proper and the combustion chamber, this restricted space is so shaped that the air flowing through it towards the combustion space moves, in the direction of the left front wall of the latter, in the form of a cone, the apex of which is located somewhere near the fuel-injection tube. The fuel-injection valve is extremely simple and no air-admission passages are needed. Neither are there any injection-valve needle, compressed-air injection flasks and the other accessories of compressed-air fuel-injection systems, which simplifies the entire design in a very material manner. (*Oel-u. Gasmachine, Motor Fahrzeuge*, vol. 18, no. 12, Dec., 1921, pp. 186–188, 4 figs., *hd*)

Kraus Fuel Oil Engine. The Kraus oil engine is an internal-combustion engine in which air is compressed in separate compression cylinders, mixed with the jet of atomized oil and ignited by an electric spark. Once this jet of gas has become ignited, it burns continuously and the resulting hot flame is brought into contact with small quantities of water which cool the gases to a working temperature. At the same time steam is generated, which, combined with the gases of combustion enters the power cylinders and performs work upon the pistons. This results in elimination of hot gases and excessive temperatures within the working cylinders. No special light fuel for starting is used, starting being accomplished directly with the oil without any previous heating by means of hand or mechanical cranking. Only one spark plug is used, and this only for igniting the initial jet of gas at the beginning of operations. Once this has been lighted it is no longer necessary. The motor is controlled by a simple throttle valve.

As regards water jackets, the cooling water enters the exhaust manifold, passes around the working cylinders and when heated to practically the boiling point, is admitted into the gas jet and converted to steam as mentioned before.

No experimental data as to power developed, fuel efficiency, amount of water used, etc., are given. The engine was exhibited at the Motor Boat Show in February, 1922, in New York City. (*Motor Boating*, Show Issue, Feb., 1922, p. 33, 1 fig., *d*)

Burning Mixtures of Alcohol and Gasoline in Internal-Combustion Engines. During the war the question of fuel for internal-combustion engines, especially those of the the automobile type, became a very acute one in France. Gasoline had to be imported from afar and it became necessary to determine whether fuel from some other sources could not be substituted for it or at least used to supplement its supplies. Even though no very large quantities of alcohol were in sight, it was decided that it would be desirable to determine the combustibility in automobile motors of mixtures of alcohol and gasoline, if only for use at some later date. The Department of Inventions asked to have this question investigated at the laboratory of the Technical Division of the Artillery, at that time under the command of Colonel Nicholardot. A report was prepared on the subject by this officer, well known as chemist and scientist, and the present article is a reprint of that memorandum. (Regarding the means by which this memorandum fell into the hands of the publishers, the latter state that they prefer to be silent in order to protect the vanities of certain French military services.)

The report investigates the following subjects: Variation of solubility of 90 per cent industrial alcohol in gasoline as determined by temperature; variation of solubility of alcohol as determined by the percentage of pure alcohol at ordinary temperatures, and for industrial alcohol, variation of solubility produced by the addition of certain quantities of ether, benzene, and benzol. Data of tests are given in the form of tables and curves.

The author comes to the conclusion that the minimum temperature at which the homogeneous system alcohol-American gasoline-benzol may exist, rises very rapidly with the water content of the alcohol. This immediately suggests a practical point, namely, that containers in which such mixtures are produced should be either carefully dried or rinsed in alcohol, the latter being then recovered. For an alcohol of a given degree of strength, the above minimum temperature of homogeneity is the lower, the greater the proportion of alcohol, the lighter the gasoline and the less the content of higher homologues (toluene, etc.) in the benzol. (*La Technique Automobile et Aerienne*, vol. 12, no. 115, 4th quarter of 1921, pp. 116–124, 6 figs., to be continued *et*)

MACHINE PARTS AND DESIGN

Double Helical Gearing, H. H. Broughton. Data on the strength of helical gearing, and particulars of a number of individual gears used for winders and haulages. In the original article two extensive tables give technical data of a number of helical gears that have been actually used, one of the tables referring to Citroen gears and the other to gears made by the Power Plant Company in England.

A typical split wheel is shown, to illustrate the method of registering the two halves by means of tool steel ferrules located at opposite ends of a diameter.

For a helical or herringbone gear of given dimensions, the moment of inertia of the teeth may be figured as 40 per cent of a hollow cylinder of the limiting dimensions, and the rim (exclusive of teeth) may be figured as a hollow cylinder. Adding 25 per cent of the sum of these two moments of inertia will make the necessary allowance for the hub and arms of the wheel. If the weight and pitch diameter only are given, the moment of inertia may be considered to be the moment of inertia due to 60 per cent of the total weight concentrated at the pitch circle. A numerical example of calculation is given. Concerning gears made by various manufacturers in England, the

author points out that the tooth, pitch and width of the wheels transmitting a given amount of power for a definite speed are by no means standardized, and a comparison of gears by four different makers is given which shows the very wide variation in practice. In particular, it is pointed out that not only is a different formula used for designing the pitch but different factors of safety are also employed. (The product of pitch and width varies directly as the factor of safety.) Thus, until quite recently one firm made it a practice to allow a factor of safety of 10 on peak loads, which corresponds to a factor of 15.5 on the rated horsepower of the motor. It should be remembered, however, that such high factors are necessary for securing durability and not actual strength or safety, so that really a durability factor, as distinct from a safety factor, is introduced. By adopting improved methods of manufacture and by careful selection of pinion material, a factor of safety of 5 or 6, reckoned on peak loads, may be regarded as sufficient to ensure satisfactory service.

A remarkable thing brought out by Table IV is that the cost of gears quoted by four firms to the same specification varied from 1183 to as high as 2875 pounds sterling. (*The Electrician*, vol. 88, no. 2278, Jan. 13, 1922, pp. 34–37, 1 fig., *dpc*) Serial article.

MACHINE SHOP

Making Spur Gears by Grinding

Grinding Hardened Gear Teeth. Description of the machinery and processes developed by a British concern (The Gear Grinding Co., Ltd., Handsworth, Birmingham, England) for finish-grinding spur-gear teeth to within definite limits of accuracy.

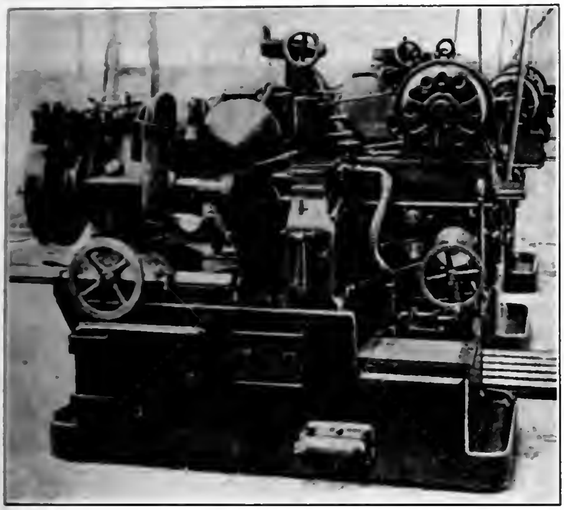

Fig. 4 General View of Machine for Finish Grinding Spur Gear Teeth

This grinding is done, of course, after heat treating, and it is stated that the finish on the surface of the work and the results obtained are far superior to the usual finishing of gear teeth with a hardened cutter.

In the present system, gashing the teeth has been reduced to a rough-milling operation, leaving on both sides of the tooth for finish grinding from 0.012 to 0.018 in. on small gears such as used in automobile gear boxes, and from 0.040 in. to 0.060 in. on large gears.

The machine is shown in Fig. 4. Briefly, the principle of operation consists of forming the edges of the grinding wheel to the desired profile of the gears being ground, and of controlling that form throughout the operation by trimming as the wheel becomes worn. In actual practice this is only necessary after the rough grinding has been completed. The bed of the machine has a reciprocating carriage at the rear, on which is mounted the wheel head. This carriage is driven by a link action, while the wheel head is fitted to a vertical slide in such a manner that end play is eliminated and the wheel head is only moved after retrimming the wheel as the cut is applied by raising the work to the wheel.

The work arbor is carried on the head shown to the left, and this also embodies the dividing mechanism for bringing each tooth into position. Both longitudinal and vertical adjustments are provided for this head—one for bringing the gear teeth into the desired position in relation to the traverse of the wheel-head, and the other for regulating the depth of cut.

This adjustment is very fine and is so arranged that extreme accuracy may be attained, and when the teeth on the first wheel of a batch have been ground to the correct depth, uniformity can be maintained throughout by working to the same setting.

It will be obvious that the degree of success obtained in the finished product depends to a great extent upon the efficiency of the indexing mechanism in the direction of precision and positive locking. A separate index-plate is, of course, required for different gears, and these are fitted to the end of the work arbor by a special type of holder which enables the notches to be set on either side in relation to the locking pawl, thereby reducing the stroke of the indexing pawl to a minimum.

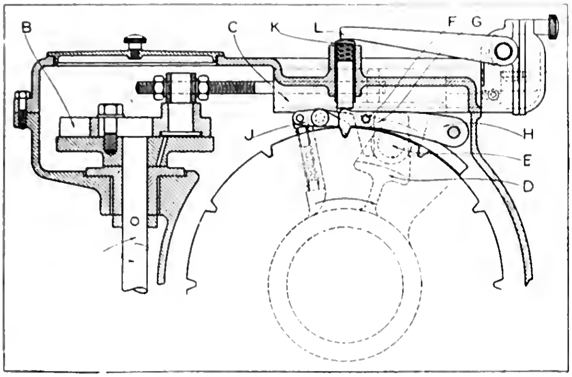

Fig. 5 Indexing Mechanism for Trimming Grinding Wheels of Gear Grinding Machine

A detailed view of this motion is shown in Fig. 5. This mechanism is actuated through the medium of the shaft *A* and the crank disk *B*, in conjunction with the sliding member *C*, which in turn operates the arm *D* through the pin *E*. Arrangements are made so that each revolution of the crank disk is synchronized with the traverse of the wheel carriage.

The dividing plate revolves in the direction indicated by the arrow, while the lever *D* travels in the opposite direction, and by reason of the small pin *F*, running on the cam face *G*, the locking pawl *H* is withdrawn from the notch, and is retained in the "open" position until the return stroke commences.

Moving simultaneously with the member *G* is the indexing pawl *J* and at the termination of the outward stroke it drops into the next notch, thus pulling the index-plate round one division on the return stroke, at the end of which the locking pawl is in its correct position over the notch. It is then pushed in by the action of the spring plunger *K*, and simultaneously the swinging lever *L* is brought into contact with the end of the plunger, firmly locking the whole mechanism until the end of the cutting stroke of the grinding wheel.

The length of stroke given the indexing pawl is regulated by moving the stud along the slot in the crank disk, while final setting is obtained by the nuts at the end of screwed portion of the sliding member *C*.

The wheel-trimming device consists of three diamonds, two arranged for trimming the concave flank edges of the grinding wheel and one for dealing with the edge that cuts on the bottom of the teeth. Means are provided to compensate for the receding of the edges of the wheel from the datum line as the wheel wears. Hitherto only spur gear wheels have been ground. It is stated that the machines here described are not made for sale, but to be used for

production purposes by the manufacturers themselves. (*Engineering Production*, vol. 4, no. 67, Jan. 12, 1922, pp. 42–44, 6 figs., *dA*)

MARINE ENGINEERING (See Steam Engineering)

The Bassett Process of Direct Manufacture of Steel from the Ore, Fritz Wuest. General discussion of the Bassett process, based on an address made by the author before the meeting of the Verein deutsche Eisenhuettenleute, November 26, 1921.

The article discusses the history of the effort to produce steel direct from the ore, and concludes that the process described cannot be carried out without losing in the slag a material part of the reduced iron. Furthermore, it is stated that the Bassett process is as little capable of securing complete reduction of metal from ore as the former processes for the direct reduction of steel. (*Stahl und Eisen*, vol. 41, no. 51, Dec. 22, 1921, pp. 1841–1848, 4 figs., *g*)

POWER-PLANT ENGINEERING

Pioneer Boilers Fired with Pulverized Coal, F. P. Coffin. An article on the history of the firing of boilers with pulverized coal. Among others, the author mentions the Bettington boiler, the boiler of the Erie City Iron Works, and of the American Locomotive Works.

Mention is made also of some of the work done in South America. (The Utilization of Coal on a Multiple Product Basis in Bacon and Hamor's book "American Fuels," abstracted through *Combustion*, vol. 6, no. 2, Feb., 1922, pp. 74–77 and 95, 2 figs., *h*)

Baffle Bridge for Cleaning Fire Under Boilers

The Gallagher-Crompton Baffle Bridge. A device for assisting in cleaning out fires under boilers.

The appliance consists of an extended platform of firebrick behind the grate, supported by standard sectional castings adapted to particular size of flue and type of grate, and inclining upwards towards the rear. The method of operation is as follows:

Without being previously burned down, the live fuel on the grate is pushed back by means of a rake on to the baffle bridge, and is there piled up, almost completely blocking the flue. The effect of this is that the cold air is prevented from entering the flues in large quantities, and combustion continues to a limited extent on the bridge. Thus the cooling of the flues is minimized and a higher percentage of CO_2 maintained. Further, the furnace door can be closed and the fire left in this condition for several minutes to allow the combustible remaining on the grate with the clinker to be burned off. The clinker and ash are now readily removed, and as the operations of the fireman are not hampered by the presence of live fuel on the grate, he is able to remove them more quickly and thoroughly than by the ordinary methods.

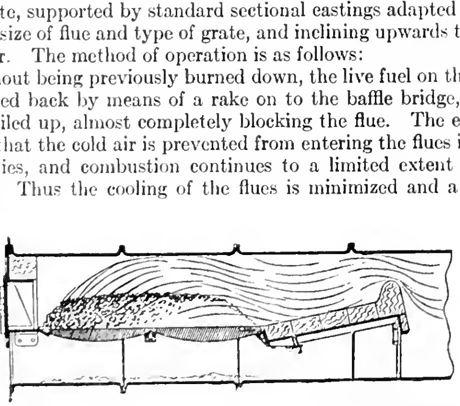

Fig. 6 Condition of Fire under Normal Methods of Cleaning

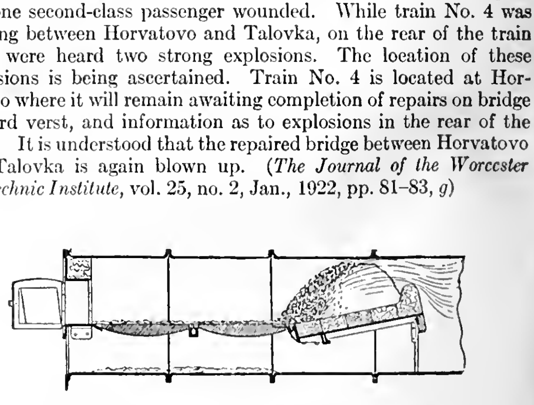

Fig. 7 Condition of Fire when Removing Clinker with Baffle Bridge

The next operation is to draw the live fuel forward again and redistribute it over the grate. Here again the baffle bridge offers advantages, for it is possible to save a much larger and hotter body of live fuel, thus enabling the firemen to recover normal furnace conditions in minimum time. Fig. 6 illustrates the condition of the fire under normal conditions, and Fig. 7 when the fire is pushed back ready for the clinker to be removed.

In tests in two plants, each comprising two Lancashire boilers and one plant equipped with the baffle bridges, it is claimed that an important saving in fuel was effected, notwithstanding the fact that in the plant equipped with baffle bridges only coke breeze was used, while the plant not so equipped used a mixture of coal and coke breeze. (*Iron and Coal Trades Review*, vol. 104, no. 2811, Jan. 13, 1922, p. 46, 3 figs., *d*)

RAILROAD ENGINEERING

Gasoline Switch Locomotive, L. C. Josephs, Jr. Description of a light-type switching locomotive, built by the International Motor Company, with many parts standard in the Mack trucks.

The locomotive is of the common steeple-cab type, with an engine located longitudinally at each end and an operating cab between, and the transmission located below the floor of the cab.

As the new engines face in opposite directions, their rotations are opposite. They are arranged, therefore, to drive through the regular clutch assemblies and bevel pinions to the opposite sides of the bevel gear on a shaft mounted across the locomotive. Thus, either one or both engines may be used as required, the clutches being controlled by adjacent pedals at the operating position. From this main bevel the drive passes through a simple reverser of the spur gear and jaw clutch type to the transmission. The driven end of this transmission carries a spur pinion geared to a cross jackshaft below, while the jackshaft carries four small sprockets and drives the locomotive axles by two 2-in. roller chains to each axle.

The locomotive on its initial test was able to start and accelerate the 600-ton train on level track. (*Railway Review*, vol. 70, no. 3, Jan. 21, 1922, pp. 82–84, 4 figs., *d*)

Railroading in Siberia, Col. Benj. O. Johnson. General discussion of the situation in Asiatic Russia. The following report is cited to give a sample of railroading under difficulties.

"The report received this morning from Pogranichya is to the effect that there was a bridge blown up at 4.30 a.m. on Ussury Ry., between Horvatovo and Lipovtzy stations. The track is damaged and eight wooden braces and the bridge foundation are also damaged, with the span in direction of Horvatovo brought down. Train No. 4 departed from Talovka on 72nd verst,[1] was fired upon, and one second-class passenger wounded. While train No. 4 was running between Horvatovo and Talovka, on the rear of the train there were heard two strong explosions. The location of these explosions is being ascertained. Train No. 4 is located at Horvatovo where it will remain awaiting completion of repairs on bridge on 53rd verst, and information as to explosions in the rear of the train. It is understood that the repaired bridge between Horvatovo and Talovka is again blown up. (*The Journal of the Worcester Polytechnic Institute*, vol. 25, no. 2, Jan., 1922, pp. 81–83, *g*)

SPECIAL MACHINERY

Cutting Metal Under Water by Acetylene Torch

Blow Pipe for Under Water Working. British Patent No. 168,929, blow pipe, designed primarily to enable oxyacetylene welding and cutting to be carried out under water. Briefly, the principle consists in utilizing compressed air to form a water-free zone around the flame of the blow pipe. The essential part is a casing having internal spiral vanes arranged so that compressed air, in passing from the rear of the casing, issues around the nozzle with a cyclonic or spiral effect, giving a region of maximum pressure at a point below the nozzle. For mounting the casing, a back plate is attached to the burner by means of a union nut, while the plate itself carries an internally screwed ring, which may be rotated to provide axial adjustment for the casing without rotation of this member relatively to the burner.

A pipe secured to the stem of the blow pipe supplies the compressed air to the space at the rear of the casing, suitable ports being provided as shown. The burner is then completed by a cup-shaped cap screwed to the outer end of the casing, and this cap may have a

---

[1] One verst = two-thirds of a mile.

series of recesses across the outer edge, or it may be provided with projections to prevent the face from being pressed into close contact with the work. (Abstracted through *Engineering Production*, vol. 4, no. 66, Jan. 5, 1922, p. 21, 1 fig., *d*)

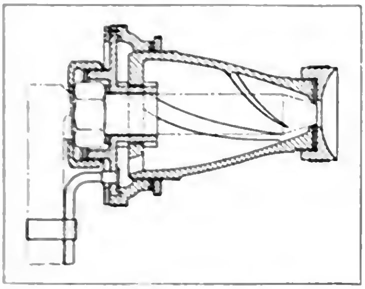

Fig. 8 Blow Pipe for Oxyacetylene Welding and Cutting Under Water

STEAM ENGINEERING

Hawthorn-Armstrong Marine Water-Tube Boiler with Superheater

Hawthorn-Armstrong Water-Tube Boiler for Merchant Ships. The purpose of the new boiler is to combine the steam generator and the superheater in one unit. Apart from the superheater elements, the new boiler has the main characteristics of the Yarrow type, but is provided with larger water surfaces and steam spaces than is usual in water-tube boilers of the ordinary type. Also, the circulation in evaporating elements is always continuous and in one direction, the outside tubes forming downcomers and thus establishing a figure-eight circulation through the cross tubes at high velocity, which scours the insides and prevents deposit even with poor feedwater.

The construction, Fig. 9, consists of four drums, *A*, which, together with the $1^3/_8$-in. diameter tubes, *B*, form the evaporating unit connected together crosswise by the tubes interlaced with each other, and three rows of downcomer tubes *C* which form the water wall at the sides.

The combustion chamber is formed under the evaporating tubes *BB*, and between the two lower water pockets *AA*.

Incorporated with the evaporating unit are the superheating tubes *FF*, which are connected to the two lower pockets *GG*, and one large central steam drum *F*, the latter being divided into three parts, *JJK*, the middle portion *K* being the superheat container, and the two wing portions *JJ* forming the passage, by way of the pipes *NN*, for saturated steam down to the lower pockets *GG* of the superheater through a portion of the tube and rising up to the central portion of the drum through the remainder of the superheating tubes *FF*, the steam being superheated in its passage through the small tubes *FF*. These tubes are 1 in. in diameter.

The experiment was made with the boiler worked with auxiliary feed make-up from water containing a large proportion of chalk and lime in solution, and also from sea water. After three weeks of continuous run the boiler was opened up; all the deposit was found in the lower drums and nothing in the tubes.

The arrangement of the superheater element is such that by manipulating three stop valves this portion can be converted into a saturated steam producer, either to supplement the total steam supply or as a precaution against damage to superheater tubes when lying under banked fires or when working engines in or out of port; that is, when little or no circulation takes place in the superheater tubes. (*The Marine Engineer and Naval Architect*, vol. 45, no. 532, Jan., 1922, pp. 10–11 and 40, 2 figs., *d*)

TESTING AND MEASUREMENTS (See Hydraulics)

The Application of the Ultra-Micrometer to the Measurement of Small Increments of Temperature, W. Sucksmith. The ultra-micrometer invented by Prof. R. Whiddington was described in *Mechanical Engineering*, Jan., 1921, p. 49. It is an instrument working with two oscillating valve circuits and measuring up to one-two-hundredth of a millionth part of an inch. In one of the circuits there is a condenser consisting of two parallel plates, and the variation in the distance of these plates produces variations in the note emitted from a telephone, thus affording a basis of measurement.

In the present experiments the method used was to attach a metal bar or tube to one of the condenser plates and measure change in the temperature of the bar by the change in the note produced in the telephone which in turn was produced by the change in length of the bar. The original article describes the installation in detail. The copper tube on which the measurement was made was heated electrically. It was found that the arrangement is capable of detecting a change of temperature of the order of one sixteen-thousandth part of a deg. cent., and it was observed that while the heating current was flowing the note emitted by the telephone changed very smoothly, showing that no discontinuity in expansion could be detected, even with an apparatus capable of measuring one two-hundredth of a millionth part of an inch.

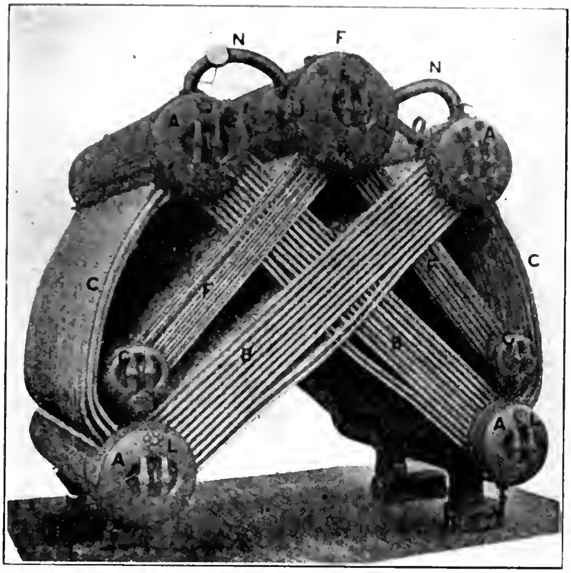

Fig. 9 Hawthorn-Armstrong Marine Water-Tube Boiler with Superheater Element

It may be mentioned in this connection that the possibility of applying the ultra-micrometer to the investigation of the relation between temperature and expansion of metals for very small increments of the former was pointed out in an editorial in *Mechanical Engineering*, Jan., 1921, p. 59, commenting on Professor Whiddington's ultra-micrometer. (*The London, Edinburgh and Dublin Philosophical Magazine and Journal of Science*, vol. 43 (6th series) no. 253, Jan., 1922, pp. 223–226, 2 figs., *ct*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society.

By introducing heat rapidly into the coal, and thus bringing about an immediate decomposition of the hydrocarbons in the cold coal, a concern at Granite City, Ill., succeeded in producing metallurgical coke from 100 per cent Illinois coal, hitherto considered as non-coking. The new product has been tried in the laboratory and in the blast furnace, and is said to have given excellent results. For further information see Making Coke from Illinois Coal, by M. W. Ditto, *Iron Trade Review*, March 9, 1922 (vol. 70, no. 10).

WORK OF THE A.S.M.E. BOILER CODE COMMITTEE

THE Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York, N. Y.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in MECHANICAL ENGINEERING.

Below are given the interpretations of the Committee in Cases Nos. 355, 375 (reopened), 377 to 383 inclusive, as formulated at the meeting of January 19, 1922, and approved by the Council. In accordance with the Committee's practice, the names of inquirers have been omitted.

CASE NO. 355

Inquiry: An interpretation is requested of the application of the formulas in the Boiler Code for crown bars to a form of reinforcement for crown sheets where the top sheet of the fire box is a half of a true circle and is braced with arch bars extending over the top and down below the top row of staybolts at the sides, these arch bars being riveted to the water side of the crown sheet through thimbles. Recommendations of the Boiler Code Committee are requested covering low pressure steam heating boilers, as well as high pressure boilers.

Reply: This construction is not covered by the Code, but when the unstayed portion of the crown sheet does not exceed 120 deg. in arc, it is recommended that the maximum allowable working pressure should be determined by adding to the maximum allowable working pressure for a plain circular furnace of the same thickness, diameter and length by the formula in Par. 239, the pressure P_1 determined from the following formula, which is a modification of that in Par. 241, section *a:*

$$P_1 = 10{,}000{,}000\ \frac{b \times d^3}{p \times D^3}$$

where

b = width of crown bar, in.
d = depth of crown bar, in.
p = longitudinal pitch of crown bar, in.
D = outside diameter of furnace, in.

providing that the maximum allowable working pressure must not exceed that determined by the formula for furnaces of the Adamson type, in Par. 242 when L is made equal to p, and also providing that the diameter of the holes for the staybolts in the crown bars does not exceed $^1/_3\ b$, and the cross-sectional area of the crown bars is not less than 4 sq. in. Par. 199 would govern the spacing of the staybolts, rivets or bolts attaching the sheet to the bars.

CASE NO. 375 (REOPENED)

Inquiry: Is it permissible, under the requirements of the Boiler Code, to weld a seam in a vertical fire box not over 38 in. in diameter and in length ranging from 20 in. up, by the autogenous or fusion process where the fire box has no support other than the tube sheet, mud ring and fire door?

Reply: It is the opinion of the Committee that, under the requirements of the Code, autogenous or fusion welding is not permissible for the seam in the firebox of a vertical-tubular boiler, unless the sheet containing the seam is properly supported by staybolting or other form of construction.

CASE NO. 377

Inquiry: An opinion is requested from the Boiler Code Committee concerning the applicability of Par. 428 of the Code relative to the composition of the tin filling for fusible plugs, if used, where the boiler is to be operated under a working pressure of from 350 to 500 lb. per sq. in., so that the temperature of the steam under working conditions will be far above that specified for the melting point of tin.

Reply: There is nothing in the Code pertaining to the use of fusible plugs on boilers operated at pressures involving temperatures near or above the melting point of tin. It is accordingly proposed to revise Par. 428 by the addition of the following:

> Where the boilers are to be operated at working pressures in excess of 225 lb. per sq. in. gage, the use of fusible plugs is not advisable.

CASE NO. 378

Inquiry: If an internal boiler feed pipe enters at full size into a steam and water drum and then into a closed vessel within the drum, wherein the end of said feed pipe is open and the said closed vessel has a series of openings, accessible for inspection and the combined areas of which openings are largely in excess of the open end of the pipe, and means are provided for blowing down the interior closed vessel, does the construction meet the requirements of Par. 314 of the Code?

Reply: If the closed vessel within the drum, into which the open end of the feed pipe projects, has openings largely in excess of the area of the open end of the pipe so that there may be no possibility for them to become clogged by incrustation and providing the vessel has means for blowing down in cleaning, it is the opinion of the Committee that the construction described will meet the requirements of Par. 314.

CASE NO. 379

Inquiry: Would it meet the requirements of the A.S.M.E. Boiler Code for an authorized inspector to stamp a boiler as a 200 lb. pressure boiler if the same meets all the requirements regarding the boiler proper but the cross connection between the drums is composed of extra-heavy pipe and extra heavy flanged cast iron fittings?

Reply: It is the opinion of the Committee that a boiler so fitted with the cross connection using extra-heavy cast-iron fittings would not meet the requirements of Par. 9 of the Code.

CASE NO. 380

Inquiry: Is it necessary, under the requirement of Par. 336*b* of the Boiler Code, that a boiler head must be stamped by the manufacturer in two places when it is less than 12 in. in diameter and, due to the tube spacing, it is impossible to find room for more than one stamping?

Reply: It is the opinion of the Committee that as long as there is one stamp legible on a miniature boiler, the intent of the Code is met, where the parts are so small that it is impossible to apply two stamps.

CASE NO. 381

Inquiry: An interpretation is requested of the requirement in the last sentence of Par. 257 that calking shall be done with a round-nosed tool, where a form of flat-faced tool of the full width of the plate is being successfully used so as to thicken out or upset the end of the plate with pressure, instead of hammering It is pointed out that with this method there is no danger of scoring or damaging the plate underneath the calking edge and the result is a very firm and effective result in calking.

Reply: It was the intent of the Committee in imposing this requirement that calking should be done so that the plate at or beneath the calking edge will not be scored or damaged. If the tool is of such shape as to upset or compress the edge of the plate without splitting it and will not score or damage the adjacent plate, the requirements of this paragraph may be considered as fully met.

CASE NO. 382

Inquiry: Is it not permissible, under the requirements of Par. 180 of the Code, to use plate thicknesses for the shells and tube

sheets of h.r.t. boilers thinner than those specified in Pars. 18 and 20, provided the maximum allowable working pressure formula gives the desired pressure with a factor of safety of 5?

Reply: It is the opinion of the Committee that it is not permissible under the rules of the Code, to use plate thicknesses in any case for shells or tube sheets less than the minimum thicknesses specified in Pars. 18 and 20 of the Code.

Case No. 383

Inquiry: Par. L-18 states in the first sentence that the gage thickness of the tubes shall not be less than a certain amount. In the second sentence it states that the gage thickness shall be measured by the B. W. gage and the thickness at any section must not vary more than one gage below or one gage above that specified. Does this require using one gage heavier than the nominal gage in order to meet the requirements?

Reply: The intent of the Committee in formulating this rule was that the gage thickness referred to in the first paragraph of L-18 of the Locomotive Code, described a nominal gage to be used. The gage thickness referred to in the second paragraph specifies that whichever gage is used, the limitations are minus one gage and plus one gage. Therefore, if a particular gage is specified for the boiler tube, the limits in gaging are one gage less and one gage more than that specified.

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A.S.M.E.

Research Résumé of the Month

A—Research Results

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a resume of research results with formulas or curves where such may be readily given, and to report results of non-extensive researches which in the opinion of the investigators do not warrant a paper.

Cement and other Building Materials A3-22. Effect of Moisture Content upon the Expansion and Contraction of Plain and Reinforced Concrete. While the properties of concrete have been investigated for many years, attention has largely been given to considerations of strength alone. Studies of the less important properties, however, are also needed to explain phenomena that are observed in reinforced concrete structures, and to give information on questions relating to the appearance and durability of the material.

Aside from the action of direct load, deformations are produced in concrete by changes in temperature and in moisture content. With reference to temperature changes in reinforced concrete, it is well known that, regardless of differences in the mixture, concrete has practically the same coefficient of expansion as steel, so that the two materials contract or expand together. Moisture content, on the other hand, has the undesirable property of affecting concrete alone. Concrete, like wood, clay, and some other materials, expands when it absorbs moisture and contracts when it is dried; steel has no such action. After the concrete is poured the steel remains unchanged with changes in moisture conditions, while concrete ordinarily shrinks a considerable amount. Aside from the stresses set up in steel and concrete by the shrinkage of the latter, the resulting formation of cracks large or small will produce a condition which may be favorable to the corrosion of the steel or the disintegration of the concrete after repeated changes from dry to wet condition.

The tests which are described were made to investigate the amount of shrinkage which may be expected in a mortar or a concrete, the relation between the change of moisture content and the change of length of these materials, the difference in shrinkage of plain and reinforced concrete, and the internal stresses set up in the latter. For purposes of comparison with the results obtained with concrete, a few tests were made on the effect of the absorption of water by sandstone and limestone.

The paper contains numerous plots which present clearly to the eye the data obtained. It also contains a theoretical discussion of Shrinkage Stresses in Reinforced Concrete and closes with the following comments in the form of conclusions.

1 Concrete expands when it absorbs moisture and contracts when it is dried. Concrete of a 1:2:4 mixture is likely to contract during hardening as much as 0.05 per cent in an ordinary structure.

2 Contraction of concrete by the loss of moisture causes stress in the concrete when it is restrained by an external force. The amount of this stress is not as small as is generally supposed.

3 The shrinkage stress caused in the steel in reinforced concrete may reach the usually accepted working stress of steel when the amount of reinforcement is less than 1.5 per cent.

4 The shrinkage stress developed in 1:2:4 concrete may reach the ultimate tensile strength of the concrete when the amount of reinforcement is greater than 1.5 per cent. With richer mixtures the increase in shrinkage stress may be relatively greater than the increase in ultimate strength.

5 The greater the percentage of reinforcement the greater the tensile stress that may develop in the concrete, and concrete having a higher percentage of reinforcement than 1.5 per cent is likely to have cracks formed unless proper provision is made.

6 In reinforced concrete out of doors, subject to alternate wet and dry conditions, cracks may readily be formed under the repeated stress which is nearly equal to the tensile strength of the concrete.

7 Reinforced concrete does not appear likely to be a durable material in a place where a corrosive influence on steel such as sea air is active, unless proper protection against the formation of shrinkage cracks is made.

8 It is suggested that the prevention of shrinkage stress in concrete might be accomplished in two ways, either by finding a cement giving less expansion and contraction, or by the use of a perfect water-proofing treatment.

9 It may be expected that an integral waterproofing compound might lessen the change of volume for a short time, but it would not prevent the final diffusion of moisture with consequent change in volume.

This paper is issued as Bulletin No. 126 of the Engineering Experiment Station of the University of Illinios, Urbana, Illinios. Price, 25 cents.

Fatty Oils, Fats and Soaps, A1-22. Cutting Fluids. See *Machine Tools A1-22.*

Heat A3-22. Thermal Expansion of Nickel, Monel Metal, Stellite, Stainless Steel and Aluminum. The increasing use of nickel, monel metal, stellite, stainless steel, and aluminum for spark plugs, steam valves, automobiles, and in household and surgical appliances has created a considerable demand for the accurate determination of the thermal expansion of these metals and alloys.

Scientific Paper No. 426 of the Bureau of Standards, which will soon be for sale by the Superintendent of Documents, Government Printing Office, Washington, D. C., at 10 cents per copy, considers this subject fully. Ten samples of commercial nickel containing from 94 to 99 per cent nickel, 5 of which were heat rolled and 5 heat rolled and annealed, 10 samples of monel metal, 60 to 69 per cent nickel, of which 2 samples were cast, 3 hot rolled, and the remaining of various compositions and treatments, 5 samples of stellite of different grades, 2 samples of stainless steel, and 2 samples of 99.4 per cent aluminum were used in the work. The conclusions should prove of assistance to engineers using these metals in connection with varying temperatures.

Machine Tools A1-22. Cutting Fluids. Technologic Paper No. 204 of the Bureau of Standards is divided into two parts, theory and practice. In the first part, the difficulties attending the proper lubrication of the cutting tool in machine work are described, and the reasons why lard oil is particularly suitable for this work are set forth. It is shown that the viscosity of an oil is not the only factor to be considered in this connection. Oils for cutting purposes should have a high adhesion, and it seems possible to improve mineral oils by adding such fluids as oleic acid, pine oil, and fixed oil.

An important function of cutting fluids is to cool the tool and chip, and for this purpose alone water with its high specific heat is well suited but it rusts the machines, and for this reason where water is used such alkaline substances as soda or soap are always added. In conclusion, part 1 suggests methods for the measurement of the adhesion of oils.

Part 2, practice, considers the correspondence which the Bureau conducted with many large machine shops throughout the country as to their experience with cutting fluids. The different kinds of oil which have been used for this purpose are listed, and attention is given to the possibility of using emulsions made up of mineral oil compounded with neutralized sulfonated oil and formed into a permanent emulsion with water.

Mineral oils compounded with alcoholic solutions of soap and a thick soap solution and mineral oil, marketed as a paste, are also described. In choosing any cutting fluid, it is pointed out that the character of the metal to be worked should be considered. Brittle metals, such as cast iron, are easier to lubricate than the so-called

"draggy" metals, such as soft steel and wrought iron. This Paper may be obtained at 15 cents a copy by addressing the Superintendent of Documents, Government Printing Office, Washington, D. C.

Paints, Varnishes and Resins A3-22. Preservation of Mine Timber. One of the recently issued Reports of Investigations of the Bureau of Mines is devoted to a study of the Growing Need for Preservation of Mine Timber. This report is written by Mr. R. R. Hornor a mining engineer of the Bureau. After demonstrating the large quantity of timber used in Mines the author discusses the decrease in the supply and quality of timber and the consequent need for general timber conservation.

The average life of untreated wooden surface structures is placed at 10 to 12 years; however, the average life of timber entering into mine and mill equipment subjected to replacement from decay is probably not over 6 to 8 years. Assuming the average period of usefulness of all kinds of mine construction is 20 years, then the timber subjected to decay will require replacement at least once during its period of service, in the case of surface structures, and twice in case of mine and mill equipment.

With proper preservative treatment of the original timber entering into this construction, it could be made to last throughout the entire period of service, thus effecting an important saving in the cost of material and labor.

To determine the advisability and economy of treating underground timber, also timber used in surface structures and equipment Barth formulated a rule which is substantially as follows: Timber that is permanent in character; that is which is not exposed to destruction by mechanical wear or crushing before the expiration of its natural life, or the usefulness of which does not cease before the advantages of chemical preservation can be realized, should be treated. Bureau of Mines, Washington, D. C., address H. Foster Bain, Director.

Petroleum, Asphalt, and Wood Products A3-22. Preservation of Mine Timber. See *Paints, Varnishes and Resins A3-22.*

Railroad Rolling Stock and Accessories A1-22. Thermal Stresses in Steel Car Wheels. See *Heat A2-22.*

Safety Devices A2-22. Survey of Elevator Interlocks in U. S. Technologic Paper No. 202 of the Bureau of Standards prepared by C. E. Oakes and J. A. Dickinson is entitled Results of a Survey of Elevator Interlocks and an Analysis of Elevator Accident Statistics.

This report gives the results of a field survey of several thousand elevator landings equipped with various types of mechanical and electromechanical interlocks and contact devices. The survey was conducted in connection with the preparation of an elevator safety code, in which work the Bureau of Standards engineers have coöperated with engineers of The American Society of Mechanical Engineers. The elevators are classified as follows: A, elevators in buildings having heavy service and where maintenance service is provided; B, elevators located in buildings where the service is heavy but without maintenance; and C, elevators on which the service is light and for which no maintenance service is provided. The statistics show that 73.8 per cent of all fatal accidents might be prevented by well-designed interlocks. Address Superintendent of Documents, Government Printing Office, Washington, D. C. Price 5 cents.

Steel Its Treatment and Products A3-22. Tensile Properties of Some Structural Alloy at High Temperatures. An investigation of this subject has been recently made by the Bureau of Standards and the results have been published as Technologic Paper No. 205. In this Paper the results are given of a number of determinations of tensile strength, proportional limit, elongation, reduction of area, and strength at fracture throughout the range 20 to 500 deg. cent. for 4 steels containing about 0.38 per cent carbon as follows: (*a*) Plain carbon steel; (*b*) 3½ per cent nickel steel; (c) 3 per cent nickel and 1 per cent chromium steel, and (*d*) 1 per cent chromium 0.2 per cent vanadium steel.

Brief reference is made to the types of fractures made in testing steels at various temperatures, and particular attention is paid to comparison of the tensile properties of these alloys at 550 deg. cent. Of the 4 steels tested in normalized condition, it appears that the two alloys containing chromium show greater resistance to weakening by increase in temperature to about 550 deg. cent. than either the plain carbon or 3½ per cent nickel steels, and at this high temperature the chromium vanadium steel is to be preferred from the standpoint of high tensile strength and limit of proportionality. The carbon and 3½ per cent nickel steels behaved alike with rise in temperature above that of the room and at about 550 deg. cent. the addition of 3½ per cent nickel appears to have but little effect upon the strength of the carbon steel. For copies of this Paper address the Superintendent of Documents Government Printing Office, Washington, D. C., 5 cents a copy.

Steel, Its Treatment and Products A1-22. Gas Cylinders. See *Gases, General A1-22.*

Transportation A1-22. Survey of Elevator Interlocks in U. S. See *Safety Devices A2-22.*

Welding A1-22. Oxyacetylene Welding and Cutting Blow-pipes. A very thorough investigation of oxyacetylene welding and cutting blowpipes was conducted by the Bureau of Standards at the request of the War Department. In this investigation special reference was given to their economy in operation, safety and design. Apparatus from 14 different manufacturers was submitted to test, and the character of the test was only decided upon after a thorough study had been made of the various operations in which these blowpipes are used.

The tests to which all the blowpipes were submitted were developed with the idea of minimizing the personal equation of the operator and securing data which were representative only of the blowpipe itself. In order to accomplish this result, a rather elaborate testing equipment, consisting of a weighing system, gage board equipment, welding table, cutting table, and safety flashback testing apparatus was designed and used throughout the investigation.

The paper describes in detail these various parts of the equipment and then considers the different classes of tests which were used for the cutting and for the welding blowpipes. The conclusions arrived at as a result of this work should prove of considerable assistance in improving the design of apparatus of this kind, with the object of securing better work, greater economy, and increased safety to the operator.

This investigation is fully described in Technologic Paper No. 200 of the Bureau of Standards, for sale by the Superintendent of Documents, Government Printing Office, Washington, D. C., at 35 cents a copy.

B—Research in Progress

The purpose of this section of Engineering Research is to bring together those who are working on the same problem for cooperation or conference, to prevent unnecessary duplication of work and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

Heat Transmission B1-22. Heat Transmission through Insulation of Dynamo-electric Machinery. A study of heat transmission through insulation, the dissipation of heat from surfaces, and the problems relating to air flow which are involved in the construction of dynamo-electric machinery is being made by the Research Department of the Westinghouse Electric and Manufacturing Co., East Pittsburgh, Pa. Address Mr. C. E. Skinner, Manager.

Highways B2-22. Tractive Resistance of Concrete Roads. See *Transportation B2-22.*

Oils B1-22. Physical and Chemical Characteristics of Oils used in meter bearings is one of the problems which are receiving attention of the Research Department of the Sangamo Electric Co., Springfield, Illinois. Address Mr. F. C. Holk, Chief Engineer.

Paints, Varnishes and Resins B2-22. The properties of Paints and Varnishes as well as those of all insulating materials employed in the construction of electric machinery are being investigated by the Research Department of the Sangamo Electric Co., Springfield, Illinois. Address Mr. F. C. Holk, Chief Engineer.

Transportation B2-22. Tractive Resistance of Concrete Roads. The tractive resistance of Concrete roads to motor vehicles is now under investigation. In the tests 1½ and 3-ton Army trucks and trailer and 7.5 ton Mack are used at variable loads and speeds with varied tire equipment, including measurement of vibrations in road material. Tire losses and internal vehicle losses are being determined in the Mason Laboratory, Yale University; the road tests are made conducted in both Connecticut and Massachusetts under Sub-Committee on Tractive Resistance of Roads, representing the War Department, Bureau of Public Roads, Highway Commissions of Conn. and Mass. Institute of Technology, Harvard University, Yale University, Society of Automotive Engineers, and National Research Council Committee on Economic Theory of Highway Improvement. Address: Major Mark L. Ireland, Q. M. C., U. S. A., Director, Room 10-219, Massachusetts Institute of Technology, Cambridge, 39, Mass.

F—Bibliographies

The purpose of this section of Engineering Research is to inform the profession of bibliographies which have been prepared. In general this work is done at the expense of the Society. Extensive bibliographies require the approval of the Research Committee. All bibliographies are loaned for a period of one month only. Additional copies are available, however, for periods of two weeks to members of the A.S.M.E. These bibliographies are on file at the office of the Society.

Mining F1-22. Subject List of Reports of Investigations. Serial No. 2316 of the Reports of Investigations issued monthly by the Bureau of Mines. This list covers all reports issued up to December 31, 1921. Address Bureau of Mines, Washington, D. C., Mr. H. Foster Bain, Director.

Petroleum, Asphalt and Wood Products F2-22. Petroleum and Allied Substances. Reports of Investigations of the Bureau of Mines Serial No. 2317. This is a continuation of the bibliography reported in the March issue as Serial No. 2305. Address Bureau of Mines, Washington, D. C., Mr. H. Foster Bain, Director.

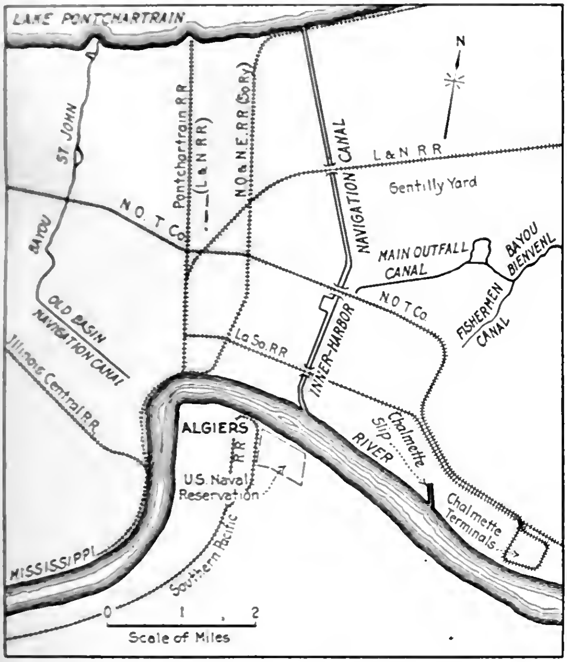
Windmills F1-22. Windmills. A bibliography of two pages. Search 3519.

NEW ORLEANS NAVIGATION CANAL NEARS COMPLETION

One of the interesting port development projects on foot in this country is the so-called Inner-Harbor Navigation Canal which will soon be completed by the City of New Orleans at a cost of upwards of $20,000,000. This new channel is expected by its supporters to be the means of greatly increasing the standing of New Orleans among the ports of the world.

The city has been handicapped in its port development by the fact that the water frontage is all publicly owned, and it has been impossible for industries to function as they do where they can own and develop their water fronts as they see fit. In recent years the Dock Board has done what it could to improve conditions, but it was not within its power to be of any benefit to industries that wanted to buy. With the opening of the new canal however, it will be possible to develop a large privately owned water frontage, which, if properly planned, should take care of the utmost requirements for many years.

So far the plans provide for the opening up of eleven miles of new water front at practically constant water level, on which long term leases will be allowed. This frontage can be indefinitely extended by lateral dredging and that part of the development has been suggested for private ownership.



New Orleans Inner-Harbor Navigation Canal

The Inner-Harbor Navigation Canal is nearly five and a half miles long and extends from the Mississippi River across the city to Lake Pontchartrain. The Inner Harbor proper starts near the river at the lock and will be at the level of the Gulf of Mexico and subject only to its tidal fluctuations. It is dredged to a depth of 30 ft. below Gulf level over a section 150 ft. wide and is 300 ft. across at the surface. A depth of from 9 to 14 ft. already exists from the Lake Pontchartrain end of the canal out to the Gulf through Mississippi Sound. Eventually this could be dredged to a depth of 30 ft., which would give deep sea-going vessels a route into New Orleans some fifty miles shorter than by the river.

The Inner Harbor will be paralleled throughout its length on both sides by the Public Belt Railroad which connects with nine railroad trunk lines and is municipally owned and operated.

The lock that is being constructed to provide for passage of vessels from the outer harbor on the Mississippi into the Inner Harbor, is sufficiently large to accommodate ships of approximately 20,000 tons. This structure contains some 90,000 cu. yd. of reinforced concrete on 24,000 sixty ft. piling. It is 1050 ft. long and has a usable length of 640 ft., a clear width of 75 ft. and a depth at low water of 30 ft. It is equipped with four sets of miter gates 55 ft. high and another set 42 ft., each gate being operated by a 52-hp. electric motor. Also there is an emergency dam consisting of eight girders 80 ft. long, 3 ft. wide and 6 ft. high which weigh about 90 tons each and which can be operated in recesses in the lock walls by an emergency dam girder bridge operated by a 300-hp. motor. The location is about 2000 ft. inside the main river levees and the channel connecting is 125 ft. at the bottom by 300 at the surface by 30 ft. deep at low water.

The Canal is crossed by four double track railroad bridges of the Strauss-Bascule type, having a clear span of 117 ft. and each bridge is provided with a 20-ft. driveway on each side.

It is expected that an immediate result of the completion of this development will be the bringing into the Mississippi River by barge, and making available to ships there, great quantities of lumber, coal, iron and other products from Louisiana, Mississippi and Alabama. (Prepared from material submitted by Walter B. Moses, Correspondent to Mechanical Engineering from New Orleans.)

Government and Industry Coöperate in Standardization

At the request of Secretary Hoover, the American Engineering Standards Committee has designated Mr. A. A. Stevenson, the retiring Chairman of the Committee, as a special representative to work with the Department of Commerce in bringing about closer and more effective coöperation between the Department's Division of Simplified Practice and the A.E.S.C.

It is the function of the Division of Simplified Practice to stimulate simplification in industry to decrease the cost of production and distribution of manufactured articles through the elimination of varieties and sizes. The work of the Division, which was organized in 1921 and is under the direction of Mr. W. A. Durgin, formerly of the Commonwealth Edison Company, Chicago, is actively under way. The A.E.S.C. has offered Secretary Hoover the use of its machinery in carrying technical projects initiated in the simplification program of the Department of Commerce. As a result of this offer Mr. Stevenson was designated as representative.

Mr. Stevenson, who is a Past President of the American Society for Testing Materials and has had a most extensive experience in standardization work, is Vice President in charge of manufacture, of the Standard Steel Works Company, which is a subsidiary of the Baldwin Locomotive Works.

Annual Meeting of Engineering Foundation Board

The Seventh Annual Meeting of the Engineering Foundation Board was held at the Engineering Societies Building in New York on February 9, 1922. The Board voted to print the Annual Report of the Engineering Foundation and the abridged report on Fatigue of Metals. Progress reports were presented on the research work of the American Bureau of Welding and on the investigation of the Properties of Steam to which the Engineering Foundation is contributing.

The Board consists of four trustees of the United Engineering Society, Messrs. George H. Pegram, Edwin Ludlow, George M. Basford and Bancroft Gherardi; eight members nominated by the governing bodies of the Founder Societies, A.S.C.E., Messrs. Edward Dean Adams and Silas H. Woodward; A.I.M.E., Messrs. Arthur L. Walker and Herbert M. Boylston; A.S.M.E., Messrs. John H. Barr and D. S. Jacobus; A.I.E.E., Messrs. F. B. Jewett and E. Wilbur Rice, Jr., three members at large, Messrs. Elmer A. Sperry, Charles F. Rand, H. Hobart Porter, and Mr. J. V. Davies, ex-officio, President U.E.S.

The following officers were elected to serve until the Annual Meeting in February, 1923: Charles F. Rand, Chairman, Edward Dean Adams, first vice-chairman, Frank B. Jewett, second vice-chairman, Joseph Struthers, treasurer, Henry A. Lardner, assistant treasurer, Alfred Flinn, secretary, Vernon Kellogg, assistant secretary, and George H. Pegram and H. Hobart Porter additional members of the Executive Committee.

The Engineering Resources and Possibilities of Muscle Shoals

J. W. Joyes

"More foolish things have been said about Muscle Shoals, pro and con, than about any other matter I ever investigated," was the gist of a remark made recently by a prominent witness before the House Military Committee in response to an inquiry about some rumor or other. It is true that, in the mass of discussion spoken and published, there has been so much misstatement and exaggeration and so much picturesque and imaginative prediction that there is difficulty in visualizing the actual physical situation and in appraising its reasonable possibilities.

The subject is large and intricate, and such a brief statement as can here be presented must be but a bare outline. It will be uncolored by prejudice and as accurate as is possible.

The term "Muscle Shoals" has been used loosely to embrace all the actualities and all the dreams that center about the Muscle Shoals section of the Tennessee River, extending some thirty-five miles upstream from the cities of Florence and Sheffield, Ala. In this thirty-five miles the river has a fall of some 130 feet, so that power-development possibilities offer advantages offsetting the navigation disadvantages but there has been much propaganda in the adjacent states for both the navigation improvement and the power development.

Importation from Chile of sodium nitrate to make nitric acid for military explosives was precarious. Therefore the Chief of Ordnance, U. S. Army, called attention to the desirability of establishing nitrogen fixation plants and advocated making such plants support themselves in peace-time by producing fertilizer material.

The chance to realize the Southern "cheap fertilizer" ideal by giving such plants cheap power, while at the same time achieving the long-desired power development and navigation improvement of the Tennessee River, led to the linking together of the nitrate plant and the Muscle Shoals propaganda, and to the inclusion in the National Defense Act of 1916 of the Section 124, which appropriated $20,000,000.00 for "Nitrate Supply."

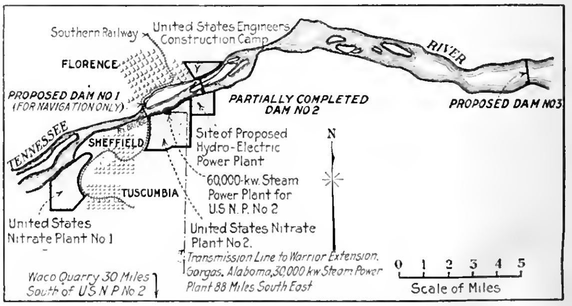
Under that law and upon the advice of a committee of prominent scientific, technical and business men, it was decided first to build a plant to make ammonia by synthesis of gaseous nitrogen and hydrogen, using a process then in a promising state of development and similar to the Haber-Bosch process then known to be successfully operated in Germany. This plant is U. S. Nitrate Plant No. 1, just southwest of Sheffield, Ala. It produced very little ammonia, due to not achieving continuous operation and the changes shown by deliberate study since 1918 to be necessary to assure efficient operation have not been made. This plant is therefore not a "going" plant and its water-gas installation, gasometers, 1500 lb. per sq. in. gas compressors, heat interchangers, reaction vessels, etc., are carried at salvage value only. There are, however, useful industrial buildings, and auxiliary plant apparatus of some value. The 1900 acres of land, 100 or so dwellings, roads, railroad, water and sewer lines, etc., will have value dependent upon the general vicinity development—small at present.

Urgent need for large quantities of explosive for munitions during the War, and other considerations combined to induce the building of the great U. S. Nitrate Plant No. 2 to make the explosive ammonium nitrate without either nitrate or ammonia from any extraneous source.

The flow sheet of this plant is briefly:

a Limestone crushed and lump coke

b Lime (in 7 kilns) and coke (crushed and dried) in



Map Showing Location of Parts of Muscle Shoals development

Twelve electric furnaces, giving calcium carbide

d Carbide, plus nitrogen (from liquid air plant) give, in 1536 ovens

e Lime-nitrogen, which when crushed and ground and treated with steam in 56 autoclaves, gives

166 tons gaseous ammonia per day

g 90 tons of ammonia oxidized in 696 catalyzers, gases giving, in 18 towers (31 × 31 × 34 ft.), dilute nitric acid (equivalent 280 tons HNO_3)

h Remainder of ammonia and the acid react in neutralizers to ammonium nitrate solution, which then concentrated and evaporated in 5 buildings give

i End product 300 tons per day, 110,000 per year, crystallized ammonium nitrate.

The rectangle embracing those processes is 5310 by 2860 ft. The seven lime kilns are 125 ft. long. The twelve electric furnaces are each 22 × 13 × 6 ft. inside have three electrodes 16 × 48 × 80 in. and use 8300 kva. The liquid air plant is the largest in the world—30 Claude units. There are twenty-nine acres of actual process buildings of standard concrete and steel-mill type.

For rated production some 90,000 horsepower is required.

As half production was needed six months after breaking ground a 110,000-volt, 33,333 kva. transmission line had to be built and contract made for part of the power requirement from an established power system. To insure continuity of this supply the United States had to build the "Warrior Extension"—a 30,000 kw. addition to the power company's steam station at Gorgas.

For the remaining power requirement, a steam power station was built at U. S. Nitrate Plant No. 2 on the river bank. This has twelve B. & W. Stirling boilers of 1507 nominal boiler horsepower, a 60,000 kw. Westinghouse Parsons double flow cross-compound

turbine in three elements and three 23,000 kva., 12,200 volt, 3-phase, 60 cycle Westinghouse generators, with surface condensers and complete accessories throughout. Fuel is dumped into overhead hoppers from standard railroad cars on a track over the powerhouse roof at about the level of the ground adjoining the gully in which the power house is located. Ample space is left in the generator room for an additional turbo-generator of 30,000 kw. or greater capacity. This plant has high efficiency and will have large value as a steam stand-by when the water power is developed and at small cost can transform 80,000 horsepower from secondary to primary power.

Nitrate Plant No. 2 has one other accessory, the limestone quarry owned in fee at Waco, 30 miles south of the plant proper. Here there is a supply of stone for probably 50 or more years. The bed is flat, with shallow overburden, giving a pit quarry which has been opened and provided with a crushing plant for 2000 tons of stone per day, with power from the transmission line mentioned. Diamond drilling, etc., show a good 50 foot thickness with average composition up to specification, that is about 98 per cent calcium carbonate.

The U. S. N. P. No. 2 site of 2300 acres, which is owned in fee, is bounded by the river, the joint tracks of L & N and Southern railroads and by highways and has 188 good dwellings besides 263 negro houses, a 100-room administration quarters, etc. All are of value to a going plant. There is also an adequate water supply system with reservoir and filter, 20 miles of sewers, 22 miles of slag and chert roads, 37 miles of railroad, an ice plant, etc.

The process plant is most carefully designed with modern material-handling devices and each process showed, upon test, high efficiency and even more than rated production. It will be seen from the flow-sheet that there are opportunities to divert all or part of several of the intermediate products to a different final product. For instance, ammonia may be diverted to be made into sulphate and the calcium cyanamide might be sold without further processing than hydrating. Other possible end-products now obvious are ammonium phosphate, urea, calcium nitrate, nitroguanadine, veronal and many others, providing of course certain additions of special process-apparatus and additional raw materials called for were made.

The original end-product, ammonium nitrate, has excellent fertilizer value containing 35 per cent nitrogen as against 21 per cent in sulphate and 15 per cent in Chile nitrate; but it is an explosive and so deliquescent that it would be troublesome to handle. This may be treated to diminish its deliquescence but is still explosive. It may be combined with sulphate giving the double ammonia salt or it may be mixed with potassium chloride thus bringing in another valuable fertilizer ingredient, potash.

The ideal of the fertilizer research man is a crystalline substance, not deliquescent, containing in soluble form the three essentials, nitrogen, potash, phosphoric acid, and as little of any other substance as possible. With that, freight need be paid upon only the plant foods and not upon useless matter such as the present commercial fertilizer contains to the average extent of 85 per cent.

Research has already produced some most promising results. Of these, electric furnacing of phosphate rock offers prospect of being a more advantageous method of rendering phosphoric acid available than the present method.

It is correct to say that in such advanced methods to be developed by the laboratory and efficient technicians lies the main hope of this plant—for ammonium nitrate is objectionable, calcium cyanamide has objectionable features limiting its use, and sulphate can, even with water power costing less than one-tenth of a cent per kwh. hardly be produced at a cost to compete with by-product coke-oven sulphate or Chile nitrate.

A word as to quantity. Of the 8,000,000 tons or so of complete fertilizer used in this country in a year (speaking very generally) nitrogen makes up only 200,000 tons. The U. S. Nitrate Plant No. 2 product, 110,000 tons of ammonium-nitrate or equivalent, contains roughly 40,000 tons of nitrogen—about one-fifth of the aggregate.

Such are the properties of the United States at Muscle Shoals—other than the dam—and such are some of the possibilities that may with reason be now predicted for them. It remains to speak of the dam and its possibilities.

Dam No. 2 (the Wilson Dam) has about 30 per cent of the permanent structure done. It is to have a normal head of 95 feet and may probably be rated as capable of delivering about 100,000 hp. primary, 100,000 hp. secondary (10-month power) with some 150,000 hp. available for six months and even more for shorter periods. If the efficient steam plant at U. S. Nitrate Plant No. 2 (80,000 hp.) and the Warrior Extension steam plant (40,000 hp.) be used as stand-by power, a corresponding amount of secondary water power is of course converted at small cost into more valuable primary power. Dam No. 1, proposed, is for navigation only and to give no power. Dam No. 3, not commenced, is planned for about 40 ft. head and would add correspondingly to the primary and secondary power usable. The pools of these dams would no more than take care of daily fluctuation. The possibilities of steam regulation by up-river storage are large, but too indefinite to discuss here. Tie-lines to other systems offer other possibilities of increase of usable power and of course industries run by the owner of the power may use very short-period power that could hardly be sold.

It is safe to say that development of this power should bring in to the vicinity many electrometallurgical industries and many electrochemical industries other than nitrogenous fertilizer. The nearby iron ore, coal, limestone, phosphate, bauxite and other minerals speak for themselves. Ferromanganese and ferrosilicon are already in production in Alabama and Tennessee. Almost to a certainty much general manufacture would spring up and power not used locally may be distributed over a large area. J. W. Joyes.[1]

Mr. Prindle's Signal Service in Patent Relief

Every member of the engineering profession should recognize the able and painstaking contribution on their behalf by Mr. Edwin J. Prindle, who, as Chairman of the Patents Committee of American Engineering Council, and as a representative of The American Society of Mechanical Engineers on that Committee, was largely instrumental in securing the passage of the Lampert Bill, providing much needed relief and increasing the salaries and staff of the Patent Office.

"Throughout the long fight from the time that the project started as embodied in the Nolan Bill, during times thereafter when it seemed that everything was against progress, and until the Lampert Bill was signed by the President, Mr. Prindle spared no personal time or effort in advancing the movement. In this work he kept his committee with him, and made sure of every step, but his fellow members do not hesitate to concede that his efforts stand out far above those who had the honor of serving with him, and they gladly accord him all the credit."

This extract from a letter by Dr. D. S. Jacobus, a co-worker with Mr. Prindle on the Patents Committee is a fitting tribute to his energy and sacrifice in advancing this important work.

The history of the enactment of the bill is familiar to many since the political procedure necessitated public hearings before committees of the Houses, and the members of the profession had to be called upon frequently to make their influence felt at Washington and to back up the Committee in its efforts.

The fight for relief was started in 1917 when the National Research Council was requested by the Patent Office itself to appoint a committee to find out what could be done about relieving a situation of inability to obtain suitable men in the Patent Office in view of the insufficiency of salaries which had only been increased eight per cent since 1848. The recommendations of this Committee resulted in the formulating of the Nolan Bill H. R. 11,984, immediately approved unanimously by the Patents Committee of the House. Mr. Prindle was appointed to this committee as a representative of the A.S.M.E. and he served as secretary.

The work was brought closer to the Engineering Societies through the agency of Engineering Council which appointed a Committee to aid in the passage of the bill, and on this Committee Mr. Prindle's name also appeared. Mr. Charles A. Terry was Chairman but soon resigned, and Mr. Prindle took his place. Mr. Prindle was also made a member of the Patent Committee of the National Association of Manufacturers, and Chairman of the Patent Committee of the American Chemical Society, the latter honor being

---

[1] Colonel Ordnance Dept., U. S. Army, Washington, D. C.

a recognition of his ability to assume the leadership in this reform.

After a hearing organized by Mr. Prindle and attended by representatives of the sixty organizations supporting it, the Nolan Bill passed the House but in the Senate it became involved with a Federal Trade Commission amendment. This amendment prejudiced the bill and the Senate failed to pass it. Then came an adjournment of Congress and the work had practically to be started all over again with the new Congress. The first step was the elimination of the Federal Trade Commission Amendment which was successful. Re-introduced into the new House by Mr. Lampert, then Chairman of the Patent Committee, the bill took his name. Opposition now came from the floor leader who held that the increases recommended were too high and that it would interfere with a bill for the general re-classification of governmental service. This necessitated another campaign to bring the bill up for a vote, which was successful in spite of strenuous opposition. The tide had now turned and the introduction of the bill into the Senate resulted in its passage without a single negative vote. The bill became law on February 18, 1922 by the signature of President Harding.

In recognition by the Patent Office of his able and painstaking work, the Commissioner of Patents presented to Mr. Prindle the pen with which the President signed the bill.

The Bill adds $451,000 to the payroll of the Patent Office, and increases the salaries of the Examiners approximately 45 per cent, and the number of Examiners 10 per cent. The Bill also contains a patent law amendment, proposed by Mr. Prindle, which will make a money recovery possible in all patent infringement cases where the patent has been held to be valid and there has been any substantial use of the invention. Heretofore the rules governing accountings in patent infringement suits have been so technical and illiberal that a money recovery has been impossible in most cases. Recently a few decisions have been rendered in which a more equitable principle has been applied to a limited class of infringement cases. The amendment makes the said principle statutory and extends its application to all classes of infringement cases. The amendment has been approved in principle by a number of United States Judges, and no judge has disapproved of it. It is believed that it will greatly stimulate the production of inventions, which is the object of the patent system.

Richard H. Rice, Manager G. E. Lynn Works, Dies

Richard H. Rice, late manager of the Lynn Works of the General Electric Co., an outstanding member of the engineering profession and a leading authority on steam turbines, died on February 10, 1922, at Bolton on Lake George, N. Y. Mr. Rice was born on January 9, 1863, at Rockland, Me. He was educated in public schools and Stevens Institute of Technology from which he received his M.E. degree.

He served his apprenticeship with the Pittsburgh, Columbus, Cincinnati and St. Louis Railroad, then becoming a draftsman at the Bath Iron Works in Maine. His enthusiasm and ability as chief draftsman with E. D. Leavitt, Cambridge, Mass., brought him the position of general superintendent of the Wm. A. Harris Steam Engine Co., Providence, R. I. Later he was secretary-treasurer of the Rice Sargent Engine Co. and the Providence Engineering Works.

In 1903 he became associated with the General Electric Co. as engineer in the turbine department of their Lynn Works where he started work on the development of the turbine to its present extensive proportions. In 1918 he was made manager of the plant.

Mr. Rice combined the qualities of a skilled engineer and inventor with marked ability as an executive. He had a warmth of human sympathy, a regard for the feelings of others and a democratic spirit which made him a man easy of approach. He leaves as a monument to his memory the plan of representation in effect at the Lynn Works whereby his fellow employees reap the advantages of a new, yet very old idea—good will, friendship and coöperation.

Many business and professional organizations counted him as a member. He became a member of The American Society of Mechanical Engineers in 1890 and from 1904 to 1907 served as one of its managers. For the first two years of its existence he was president of the Associated Industries of Massachusetts; he was a past-president of the National Conference of State Manufacturers' Associations. He was also a member of the Providence Engineering Society and the American Institute of Electrical Engineers. He was a member of the Boston Chamber of Commerce, a director of the Lynn Chamber of Commerce, a member of the State Committee on Unemployment and during the War served as a member of the Lynn Fuel Commission. He was the author of several technical papers dealing with turbine engines and the inventor of some fifty patented devices for use of steam, air and water, chief among which was his design for the first turbo-blower for blast furnaces in America. In June of 1921 he was awarded degree of Doctor of Engineering by Stevens Institute.

U. E. S. Report for 1921

The report[1] of the treasurer of United Engineering Society for the calendar year 1921 shows a balancing account on December 31, 1921, of $26,434.31, as compared with a balancing account on December 31, 1920, of $16,954.72. The cash on hand as of December 31, 1921 amounted to $14,219.35. Following is a statement of the treasurer's receipts and payments for the year:

RECEIPTS

Cash on hand January 1, 1921		$15,029.02
From Founder and Associate Societies for offices, storage, halls, telephones and miscellaneous	$98,666.45	
From societies not in building for halls and miscellaneous	17,530.79	
For Library, General Maintenance and Operation	25,291.61	
For Library Service Bureau	16,738.16	
For Library Recataloguing	12,291.53	
Income collected on Investments and Deposits of U. E. S.	12,116.83	
Income collected on Engineering Foundation investments	24,533.57	
Sale of Securities	27,874.38	
From A. I. E. E. for Building Addition	2,500.00	237,543.3
		$252,572.34

PAYMENTS

To Engineering Foundation		
Income from Investments less Collection charges	$24,258.31	
For Securities purchased	25,400.00	
" Building Operating expenses	101,370.21	
" Library	27,588.43	
" Library Service Bureau	15,755.41	
" Library Recataloguing	13,606.01	
" A.S.M.E. Note	2,500.00	
" A.S.M.E. Interest on note	206.20	
Collection, custodial and Adv. charges and exchanges	650.83	
For Engineering Council	14,500.00	
" Engineering Soc. Service Bureau	406.74	
" Permanent Improvement charged to capital	1,786.36	
" Renewals in steam system charged to Depreciation and Renewal Fund	9,395.91	
For American Delegation Dinner	805.10	
" Miscellaneous	123.48	
Grand total		$238,352.99
Cash on hand December 31, 1921		14,219.35
		$252,572.34

The assets and liabilities as of December 31, 1921, were as follows:

ASSETS

Property		$1,959,140.67
Land	$510,000.00	
Building	1,361,969.51	
Equipment	33,171.16	
Founders' Preliminary Expenses	24,000.00	
Investments Foundation		502,066.05

NEWS OF OTHER SOCIETIES

American Institute of Electrical Engineers

The tenth annual Midwinter Convention of the American Institute of Electrical Engineers was held in New York, February 15 to 17, 1922. This function is traditionally devoted to the presentation and discussion of highly technical subjects.

President McClellan opened the first session Wednesday afternoon with a short address emphasizing the opportunities of the engineering profession in the readjustment and developing of the country at the present time. He considered the transportation problem one of the most important and suggested that electrification of railroads might be the solution. He also pointed out that with greater development of power sources, a trend which is already making itself felt, the age will be one where engineering genius of every type and especially along electrical lines will more than ever be in demand.

The papers were then presented: The Key West-Havana Submarine Telephone Cable System, by W. H. Martin, G. A. Anderegg and B. W. Kendall; Submarine Cable Telegraphy, by J. W. Milnor; and Printing Telegraph Systems Applied to Message Traffic Handling by A. H. Reiber.

In the evening the Questionnaire on Lightning Arresters, by F. L. Hunt was read and it was followed by Deviations from Standard Practice in Lightning Arresters, by E. E. F. Creighton, and Condenser Discharge through a General Gas Circuit by Charles P. Steinmetz.

On Thursday morning, after the meeting was opened by the President, E. B. Meyer, chairman of the Transportation and Distribution Committee presided. Papers were presented as follows: The Peterson Earth Coil, by R. N. Conwell and R. D. Evans; the Effect of Moisture on the Thermal Conductivity of Soils, by G. B. Shanklin; Five Hundred Tests on the Dielectric Strength of Oil, by J. L. R. Hayden and W. N. Eddy, and An Analytical Investigation of the Causes of Flashing of Synchronous Converters, by E. B. Shand.

H. R. Woodrow, Chairman of the Protective Devices Committee, occupied the chair in the afternoon and the following papers were read: The Use of Superimposed Imaginary E. M. Fs., Currents and Fluxes in the Solution of Alternating-Current Problems, by V. Karapetoff; Question on the Economic Value of the Overhead Grounded Wire by E. E. F. Creighton; Wave Form and Amplification of Corona Discharge by J. B. Whitehead and N. Mouye; Prevention of Transient Voltage in Windings, by J. Murray Weed.

On Thursday evening the Edison Medal was presented to Cummings C. Chesney which was followed by an address on Colloids by Dr. W. D. Bancroft.

Friday morning C. E. Skinner acted as chairman and the papers were: Heating of Railway Motors in Service and on Test Floor Runs, by G. E. Luke and The "Indumor," by V. Karapetoff.

The following papers were read by titles only: Skin Effect and Proximity Effect in Tubular Conductors, by Herbert Bristol Dwight, Heat Losses in Stranded Armature Conductors, by Waldo V. Lyon, Current Locus of Single-Phase Induction Motors, by J. K. Kostko, and Polyphase Commutator Machines, by A. B. Field.

Friday afternoon about 300 members registered for an inspection trip to various power plants and in the evening the usual dinner dance was held at the Hotel Astor, completing a most beneficial and enjoyable convention.

American Institute of Mining and Metallurgical Engineers

The 125th meeting of the American Institute of Mining and Metallurgical Engineers was held in New York, Feb. 20-23, 1922. The total registration of 744 members and 587 guests was larger than in any previous year and it was considered the most successful convention ever held by the Institute.

At the annual business meeting three new officers, headed by Arthur S. Dwight, Director and President, and five new directors, were elected.

From Monday afternoon through Wednesday afternoon there were four simultaneous sessions being carried on both morning and afternoon. Of these the symposium on Foreign Oil Possibilities and Details of the Oil Industry aroused the greatest interest and attracted the largest attendance. The first two sessions were devoted to addresses by eighteen different men on Oil Reserves in the various countries and continents.

The Mining Sessions, also four in number, were well attended throughout, and 30 papers covering subjects from Sampling and Estimating Ore Deposits to General Outlines for Obtaining Data were read. The latter was in connection with the collecting of data from all the big mines of the United States for the benefit of those who contemplate making a choice in mining methods.

There were three Safety Sessions, joint meetings of the Mining Section of the National Safety Council and Industrial Relations Committee of the Institute. The first was on Wire Ropes and Hoisting, the second on Ventilation and the third dealt with miscellaneous features.

The Session on Industrial Relations included reports from subcommittees on Americanization all along the line to Mental Factors in Industry and Safety. A paper was also read on Preservation of Natural Scenery and Attractiveness of Mining Camps.

The Institute of Metals Division had two sessions in which nine papers were read and a lecture given by Prof. Wilder D. Bancroft on Colloid Chemistry and Metallurgy attracted a great deal of interest.

One of the two Iron and Steel Sessions was in memory of Prof. J. W. Richards who was for many years its very able and efficient chairman. Seven papers were read at the two meetings.

Other features were: A noteworthy joint meeting with the Mining and Metallurgical Society, considered by some a rival organization, and at which five papers on Waste in the Mining Industry were read; a Local Sections Convention, which was a most successful innovation; and entertainments. The latter included the annual smoker on Monday night at which J'Aime presented the Folies Minieres, a Review with Pangs; and the annual banquet and ball in the Grand Ball Room of the Pennsylvania Hotel. An informal dance, reception and excursions contributed toward making it the pleasantest as well as the most successful convention in the history of the Institute.

American Boiler Manufacturers' Association

The winter meeting of the American Boiler Manufacturers' Association was held at the Fort Pitt Hotel, Pittsburgh, Feb. 13, 1922, A. G. Pratt of the Babcock and Wilcox Company presiding. Secretary H. N. Covell reported the Association having 77 active and 20 associate member companies. For the Committee on Ethics, George B. Bach reported that no breach of the Association's Code had been reported in spite of strenuous competitive conditions during the preceding year.

A report from the committee appointed to determine how thoroughly the A.S.M.E. Code is being lived up to by members of the Association was presented by W. C. Connelly. To the question, "Are you complying with the A.S.M.E. Code, par. 14, 28, 36, 180 and interpretation no. 295?" fifty replied "Yes," one "No," and three "Not always." Other questions such as the advisability of having the Code Committee set a maximum thickness for shell plate and what that thickness should be, brought varying replies.

Of the 36 who answered the first part only ten opposed a maximum, but when it came to setting a figure the opinions varied from $^7/_{16}$ to $1^1/_4$ in. Seven favored $^5/_8$ and six suggested $^9/_{16}$ in. An inquiry as to the use of a single sheet for boiler bottoms brought forth a good deal of discussion, the concensus of opinion seeming to be that plates about an inch thick if of sufficient tensile strength are much better than heavier ones.

Mr. C. W. Gorton presented a paper on the National Board of Boiler and Pressure Vessel Inspectors and its relation to the Boiler Manufacturing Industry. Through a policy of One Code, One Stamp, One Inspection, this Board makes it possible to have a boiler accepted in any of a constantly growing number of states, if it is according to the A.S.M.E. Code.

An invitation was received from the American Society of Mechanical Engineers for the Association to appoint a representative on the Committee on Bolts, Nuts and Rivets.

Engineering Institute of Canada

The Engineering Institute of Canada held its annual meeting at the Montreal headquarters, January 24 and 25, 1922. The officiers elected for 1922 include, President, J. G. Sullivan, consulting engineer; and vice-presidents, Brigadier General C. B. Mitchell and Arthur Surveyer.

Three new branches were founded, one at Sydney, Nova Scotia, one at London, Ontario, and one at Lethbridge, Alberta. Among the most interesting technical papers were: An explanation of the design features of the latest hydroelectric development of the Shawinigan Water and Power Co., by Julian C. Smith, who is a vice-president and general-manager of the company; and an illustrated lecture by Major Draper on the construction of the new St. John cantilever bridge.

The entertainments included a visit to the Dominion Engineering Works at Rockfield, the annual banquet and a smoking concert.

LIBRARY NOTES AND BOOK REVIEWS

Airplane Engine Encyclopedia. By Glenn D. Angle. First edition. Otterbein Press, Dayton, Ohio, 1921. Cloth, 6×9 in., 547 pp., illus., diagrams, $7.50.

A reference book for those interested in airplane engines. Contains information concerning the design, sizes, construction and performance of the engines of about one hundred and seventy-five makers, arranged by names. Based on information from original sources and the leading books and periodicals. Includes every engine known to the author.

Architects' and Builders' Handbook. By Frank E. Kidder. Seventeenth edition. John Wiley & Sons, Inc., New York, 1921. Fabricoid, 4×7 in., 1907 pp., illus., tables, $7.

Two new chapters, on Specifications for the Steelwork of Buildings, and on Domical and Vaulted Structures, have been prepared for this edition. The chapters on Fireproofing of Buildings and on Reinforced-Concrete Construction and the sections on Heating and Ventilation and on Chimney Construction have been rewritten. In addition the whole text has been revised, numerous new articles inserted and a new index made. The total additions amount to 90 pages. The book is intended to contain information on every subject, except design, likely to come before an architect, structural engineer, draftsman or builder, and to be a thorough handbook of architectural engineering.

Automotive Repair. By J. C. Wright. Vol. 1. John Wiley & Sons, Inc., New York, 1921. Cloth, 6×9 in., 530 pp., illus., diagrams, $3.50.

This book is for the repairman or owner who is expected to make general repairs and keep a car fit for operation. One hundred and eighteen jobs are given, with complete instructions. These are divided into chassis, engine, electrical, body and radiator work and "trouble shooting," and cover, it is said, 95 per cent of all the problems which will confront the repairer. The second section of the book presents the theoretical and mechanical information required to understand the construction and operation of the automobile.

Burning Liquid Fuel. By William Newton Best. [Revised edition.] U. P. C. Book Co., Inc., New York, 1922. Cloth, 6×9 in., 341 pp., illus., diagrams, $4.

This revised and enlarged edition of Dr. Best's book, formerly entitled the Science of Burning Liquid Fuel, is a plain, straightforward summary of long practical experience in designing and erecting oil-fuel installations. Specific information is given upon the use of liquid fuel in many industries and upon all the various forms of equipment. Drawings show how the equipment is applied to various purposes. The book discusses, among other topics, locomotive, stationary, marine and low-pressure boiler equipment; practice in foundries and forge shops; and equipment suitable for the sugar, copper, ceramic, cement, baking, candy and oil industries.

Deep Well Drilling. By Walter H. Jeffery. W. H. Jeffery Co., Toledo Ohio, 1921. Cloth, 6×9 in., 531 pp., plates, illus., diagrams., tables, $5.

The author has undertaken to cover the two methods most generally used, the cable tool and the hydraulic rotary, including the building of the derrick, drilling, handling casing, fishing lost tools and the completion of the well, according to the best practice of the day. Supplementary chapters deal with oil and gas geology, cost of drilling, strength of materials and laws relating to gas and oil wells; other general information of use to the driller is also included.

Design of Steel Mill Buildings and the Calculation of Stresses in Framed Structures. By Milo S. Ketchum. Fourth edition, rewritten. McGraw-Hill Book Co., Inc., New York, 1921. Fabrikoid, 6×9 in., 632 pp., illus., diagrams, $6.

Covers the calculation of the stresses in framed structures and also the design of buildings having a self-supporting steel frame with a light covering, usually fireproof. In this edition the book has been rewritten, enlarged and reset. It is intended as a textbook in structural engineering and also as a book of reference for engineers.

Part 1 covers the calculation of the stresses in simple beams, trusses, portals, the transverse bent and the three-hinged arch. Part 2 covers the calculation of the deflections of structures, the stresses in statically indeterminate girders, trusses and frames, and secondary stresses in trusses. Part 3 covers the design of steel frame buildings for mines, mills, smelters and other industrial plants. The appendix is a complete specification for steel frame mill buildings.

Elements of Fractional Distillation. By Clark Shove Robinson. First edition. McGraw-Hill Book Co., Inc., New York, 1922. (International chemical series.) Cloth, 6×8 in., 205 pp., tables, diagrams, $2.50.

This book explains the principles of fractional distillation and illustrates them by carefully selected examples of their application. The first portion of the book treats of fractional distillation from the qualitative viewpoint of the phase rule; the second discusses some quantitative aspects from the engineering point of view; and the third section treats of the design of distilling apparatus. Part four gives examples of modern apparatus for distilling ammonia benzolized wash oils and alcohols. An appendix of useful tables is included.

Essentials of Industrial Costing. By George S. Armstrong. D. Appleton and Co., New York, 1921. Cloth, 6×9 in., 297 pp., tables, forms, $5.

This book is concerned solely with the principles and methods by which the cost of production may be determined. It is based upon an extended experience in many different industries and represents the author's mature views. The book shows the purpose of costing, summarizes good practice and is a guide to the analysis necessary for the establishment of costing systems.

Etude Geometrique des Transformations Birationnelles et des Courbes Planes. By Henri Malet. Gauthier-Villars et Cie, Paris, 1921. Paper, 7×10 in., 259 pp., diagrams, 32 fr.

A study, by synthetic methods, of birational transformations and plane curves. It strives particularly to establish the first principles and to set forth precisely, in logical and geometrical fashion, the conditions under which the homographic correspondence of laws is based. The author's exposition of modern geometry is based on the methods of Chasles and Poncelet.

Handbuch der Drahtlosen Telegraphie und Telephonie. By Eugen Nesper. Julius Springer, Berlin, 1921. Cloth, 7×10 in., 2 vol., illus., diagrams.

Dr. Nesper's book on radio communication attempts an exhaustive survey of the subject from a modern point of view and from every aspect. It is apparently more extensive than any previous work on the subject. It has been planned for easy reference, the material having been so arranged that each chapter is a complete account of a certain topic, so that reference to other chapters, or systematic reading of the whole work, can be avoided. The theory of radio communication, its history, uses, the measuring and detecting instruments, the physical phenomena in quasi-stationary circuits, coupling, damping, radiating, the technique and apparatus of high frequency measurements are described in volume one. Volume two describes typical radio stations for different purposes, and their apparatus, the uses of radio communication in railroading and radio telephony. It also includes a valuable bibliography of the important books and articles. Good indexes are provided.

History of Aeronautics. By E. Charles Vivian. Harcourt, Brace and Co., New York, 1921. Cloth, 6×9 in., 521 pp., plates, portraits, $5.

The author of this work says that hitherto there has been no attempt to furnish a detailed account of how the aeroplane and the dirigible of today came into being, but each author has devoted his attention to some special phase or period. In this book he attempts to record the facts of development and to state, as fully as is possible within the compass of a single volume, how flight and aerostation have evolved.

Hydroelectrical Engineering. By Richard Muller. G. E. Stechert & Co., New York, 1921. Cloth, 7×10 in., 431 pp., diagrams, $6.

A systematic exposition of those principles of hydraulic and electrical engineering which underly the design of hydroelectric plants. Intended for engineers engaged in designing and constructing plants or reporting on their commercial possibilities.

Hydraulics and Its Applications. By A. H. Gibson. New edition, revised and enlarged. D. Van Nostrand Co., New York, 1921. Cloth 6×9 in., 813 pp., illus., diagrams, $6.

This book opens with a description of the physical properties of water, followed by a brief treatment of the fundamentals of hydrostatics. The science of hydraulics is then presented, first theoretically and then with regard to its application to the design of hydraulic machinery. The work is written primarily for students, but the author hopes it may also prove of value to those actively engaged in the practice of hydraulic engineering. This edition has been practically rewritten, with considerable additions and much rearrangement of the material.

La Loi de Newton est la Loi Unique. By Max Franck. Gauthier-Villars et Cie, Paris, 1921. Paper, 6×10 in., 158 pp., 12.50 fr.

The question considered in this book is whether it is possible, with our present knowledge, to formulate the law governing the mechanism of the universe. Upon two postulates, that all potential energy resides in the absolute space of the physicist, and that all matter is formed of an element of inertia movable in space, the author erects a hypothesis, and compares its consequences with known facts, to determine how nearly the two agree. The first consequence is the confirmation of Newton's law, which may now be given its exact interpretation; this is the reason for the title given the book. The author's theory uses only the notions of space, time, force and inertia admitted in Euclidean geometry and mechanics.

Manufacture and Uses of Explosives. By R. C. Garmer. Sir Isaac Pitman & Sons, Ltd., London and New York, 1921. (Technical primer series.) Cloth, 4×6 in., 116 pp., diagrams, $0.85.

Information on explosives is so scattered and so much concerned with the details of individual explosives, that some difficulty is experienced in obtaining a general view of the nature and functions of explosives. The present work endeavors to provide this within a short compass, dealing first briefly with the historical development of explosives, and then with the manufacture and use of those most used today. Includes a brief bibliography.

Die Pressluftwerkzeuge. By P. Iltis. Second revised edition. Vereinigung Wissenschaftlicher Verleger, Berlin, 1921. (Goschen Collection.) Cloth, 4×6 in., 117 pp., illus.

After a brief general and historical introduction, this little book treats of the application of compressed air to hammers, percussion drills, punching, stamping and riveting machinery, drills, hoists and blasting machines. Within its limits, a large amount of information is given on the practical uses of compressed air.

Special Libraries Directory. Edited by Dorsey W. Hyde, Jr. Special Libraries Association, Washington, 1921. Paper, 6×9 in., 123 pp. $2.

This directory is a comprehensive survey of the specialized collections of literature upon various subjects in the United States. Over 1300 libraries belonging to universities, societies, business houses and other agencies are listed, with their location, rules for use and brief accounts of their resources. The list is arranged by subject and also geographically. Many of these libraries are concerned with engineering and allied subjects. The list will prove valuable to research students, in indicating possible sources of information.

Steam Boiler Maintenance. By Reg. Clayton. Sir Isaac Pitman & Sons, Ltd., London and New York, 1921. (Pitman's technical primers.) Cloth, 4×6 in., 118 pp., diagrams, $0.85.

This brief account of good practice is clearly written in language devoid of unnecessary technicalities. The author hopes it will illustrate how breakdowns may be avoided and maintenance costs reduced by systematic supervision. It is not intended to be a guide for firemen so much as to show the weak spots in the apparatus and to lead to the discovery and remedying of incipient defects and malpractices.

System Building and Constructive Accounting. By Raymond D. Willard. First edition. McGraw-Hill Book Co., Inc., New York, 1922. Cloth, 6×9 in., 307 pp., forms, $4.

A textbook for students of accounting, devoted to the design of systems for various lines of business. The book analyzes a number of systems in use, thus illustrating the principles involved, and illustrates by charts and forms suitable methods for the necessary records

Die Warmwasserbereitungs, und Versorgungsanlagen. By Wilhelm Heepke. Second edition, revised and enlarged. R. Oldenbourg, München, 1921. (Oldenbourgs Technical Handbook No. 5.) Paper, 6×9 in., 706 pp., diagrams, 120 M.

An exhaustive treatise on the installation of hot water plants, covering the subject in great detail. Confined to water-heating systems for domestic and industrial use. Methods of heating, boilers, piping, regulating and measuring instruments, insulating, etc., are fully covered.

Wharf Management, Stevedoring and Storage. By Roy S. MacElwee and Thomas R. Taylor. Appleton and Co., New York, 1921. Cloth, 6×9 in., 350 pp., forms, diagrams, tables, $5.

This, it is said, is the first book to deal comprehensively with wharf administration, the loading and unloading of cargoes, and the handling and storage of outward and inward freight. It describes the duties of pier superintendents, receiving clerks, tally men and foremen of stevedores. Other chapters deal with wharf layout and construction, cargo-handling machinery, longshoremen, labor problems. Particular attention is given to the economic aspects of the subject.

THE ENGINEERING INDEX

(Registered United States, Great Britain and Canada.)

THE ENGINEERING INDEX presents each month, in conveniently classified form, items descriptive of the articles appearing in the current issues of the world's engineering and scientific press of particular interest to mechanical engineers. At the end of the year the monthly installments are combined along with items dealing with civil, electrical, mining and other branches of engineering, and published in book form, this annual volume having regularly appeared since 1906. In the preparation of the Index by the engineering staff of The American Society of Mechanical Engineers some 1200 technical publications received by the Engineering Societies Library (New York) are regularly reviewed, thus bringing the great resources of that library to the entire engineering profession.

Photoprint copies (white printing on a black background) of any of the articles listed in the Index may be obtained at a price of 25 cents a page. When ordering photoprints identify the article by quoting from the Index item: (1) Title of article; (2) Name of periodical in which it appeared; (3) Volume, number, and date of publication of periodical; (4) Page numbers. A remittance of 25 cents a page should accompany the order. Orders should be sent to the Engineering Societies Library, 29 West 39th Street, New York.

AERONAUTICS

Research. Aeronautic Research, Joseph S. Ames. Jl. Franklin Inst., vol. 193, no. 1, Jan. 1922, pp. 15–28, 17 figs. Describes types of investigations in progress in aeronautics and methods pursued, with especial reference to wind-tunnel experiments.

The Importance of Research in Aeronautics. Flight, vol. 14, no. 4, Jan. 26, 1922, p. 55. An epitome of views of Council of Royal Aeronautical Soc. on need for better safeguards to prevent submerging of applied scientific research in aeronautics by technical experimental work.

AIR

Liquefaction and Separation. The Liquefaction and Separation of Air (Luftverflüssigung und Lufttrennung), Richard Linde. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 52, Dec. 24, 1921, pp. 1356–1360, 4 figs. Air liquefaction considered as connecting link between the compressed-air and refrigerating industry; physical principles, and the different working processes. Notes on air separation; arrangement of large modern plants; present efficiency and future prospects.

AIR COMPRESSORS

Piston. Modern Piston Compressors (Neuzeitliche Kolbenkompressoren), P. Ostertag. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 52, Dec. 24, 1921, pp. 1325–1332, 28 figs. Points out increasing importance of compressed air and its influence on design of piston compressors. Notes on standardization and simplification, drive and regulation. Experimental results with modern types of German low- and high-pressure compressors.

Sullivan Angle-Compound. Angle-Compound Air Compressors at a Colliery. Engineer, vol. 133, no. 3448, Jan. 27, 1922, pp. 111–112, 5 figs. Details of compressor installed at Bowden Close Colliery near Newcastle-on-Tyne, England, consisting of two angle-compound compressors made by Sullivan Machy. Co., Chicago, arranged on each side of, and driven in common by, a 350-hp. Allis-Chalmers self-starting synchronous motor.

Turbo-Compressors. Turbo-Compressors and Blowers (Turbokompressoren und -gebläse), H. Baer. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 52, Dec. 24, 1921, pp. 1333–1338, 14 figs. Notes on operation, basis of calculation and construction of modern turbo-compressors; speed, number of stages, losses, housing and intermediate cooling, regulation. The so-called "pumping" and its prevention. Comparison of piston and turbo-compressors. Useful field.

AIR CONDITIONING

Aero-Hydro-Fan-Separator. Improvements in the Process for Drying and Cleaning Air Mechanically, William J. Baldwin. Am. Soc. Heat. & Vent. Engrs. Jl., vol. 28, no. 1, Jan. 1922, pp. 49–52, 1 fig. Describes recent improvements made in fan known as an aero-hydro-fan-separator, for washing, drying and conditioning air.

Factories. Industrial Hygiene in Workshops (Ueber gewerbehygienische Einrichtungen in Arbeitsräumen), Otto Brandt. Glasers Annalen, vol. 89, no. 12, Dec. 15, 1921, pp. 149–152, 3 figs. Notes on dust-removal plants, most important parts of which are (1) exhaustor, (2) draft tubes, (3) pressure tubes, and (4) centrifugal dust separator; suction plants for drawing off of smoke, gases and acid fumes; and installations for utilization of flue-gas waste heat for generation of warm air.

Novel Scheme For Regulating Humidity in an Airplane Propeller Factory, A. C. Knauss. Heat. & Vent. Mag., vol. 19, no. 1, Jan. 1922, pp. 33–36, 4 figs. Details of air-conditioning apparatus developed at U. S. Forest Products Laboratory at Madison, Wis. From paper published by Forest Prod. Laboratory in Coöperation with Univ. of Wis.

AIRCRAFT

Armament Limitation Conference. Text of the Conference Discussion on Aircraft. Aerial Age Weekly, vol. 14, no. 21, Jan. 30, 1922, pp. 490–492. Text of official communiqué issued by Conference on Limitation of Armament dealing with discussion of aircraft in session of Committee on Limitation of Armament.

The Washington Conference and Aircraft. Aviation, vol. 12, no. 5, Jan. 30, 1922, pp. 128–132. Report of Sub-committee on limitation of aircraft as to numbers, character and use.

Maintenance. Canadian Technical Memoranda. Aviation, vol. 12, no. 4, Jan. 23, 1922, pp. 105–106. Copy of technical memoranda issued by Canadian Air Board, on aircraft maintenance.

Strength of Great Powers. Air Strength of the Great Powers. Aviation, vol. 12, no. 6, Feb. 6, 1922, pp. 164–166. Tables prepared by sub-committee on aircraft of Washington Conference giving authorized and actual air strength data for United States, France, Great Britain, Italy and Japan.

AIRPLANE ENGINES

Fuel Pump. The "Sylphon" Fuel System for Liberty "12" and Wright Model "H" Engines. Aerial Age Weekly, vol. 14, no. 19, Jan. 16, 1922, pp. 440–442, 5 figs. Describes sylphon pump designed to fill need for an engine-driven fuel pump to obviate use of air pressure where sufficient gravity head is not available. From Air Service Information Circular, vol. 3, no. 281.

Installation. Engine Installation, R. K. Bagnall-Wild. Flight, vol. 14, no. 4, Jan. 26, 1922, pp. 56–57. Discusses need for improvement, and principal features which are required for evolution of a sound installation.

Tests. British Tests for Aircraft Engines, Aerial Age Weekly, vol. 14, no. 19, Jan. 16, 1922, pp. 438–439. Gives schedule of standard tests to determine airworthiness of aircraft engines, issued by British Air Ministry.

AIRPLANE PROPELLERS

Levasseur Adjustable. The Levasseur Adjustable Propeller (L'hélice à pas variable Pièrre Levasseur). L'Aerophile, vol. 29, no. 23–24, Dec. 1–15, 1921, pp. 18–19, 2 figs. Especially useful for flying at high altitude.

AIRPLANES

Aerofoils. New Method for Testing Aerofoils in Flight, F. H. Norton. Aviation, vol. 12, no. 5, Jan. 30, 1922, pp. 134–136, 4 figs. Consisting in suspending an aerofoil from an airplane and measuring resultant force by tension in wires. N. A. C. A. Technical Note No. 77.

Bombers. The Wibault Night Bomber. Flight, vol. 14, no. 2, Jan. 12, 1922, pp. 21–22, 2 figs. French all-metal airplane; wing spars built of duralumin sheet; engine, 600-hp. Renault; speed at 6500 ft., 125 m.p.h.; total loaded weight, 9450 lb.

British. Aeronautics in 1921. Engineer, vol. 133, no. 3445, Jan. 6, 1922, pp. 18–21, 13 figs. partly on supp. plate. Review of British airplanes constructed during year.

Commercial. The "Bristol" 10-Seater Commercial Aeroplane. Flight, vol. 14, no. 3, Jan. 19, 1922, p. 39, 1 fig. 400-hp. Bristol "Jupiter" engine; speed at ground level, 112 m.p.h., speed at 5000 ft., 110 m.p.h.

The D.H. Type 34 Commercial Biplane. Flight, vol. 14, no. 1, Jan. 5, 1922, p. 4, 3 figs. 450-hp. Napier "Lion" engine; wing area, 590 ft.; weight, empty, with water, 3365 lb.; useful load, 10 passengers, 2000 lb. freight, 80 gal. petrol; cruising speed, 105 m.p.h.

Development. Short Survey of the Development of Air Traffic (Kort overzicht over de ontwikkeling van het luchtverkeer, met inleiding tot het bezoek aan den Rijks Studiedienst voor de luchtvaart), E. B. Wolff. Ingenieur, vol. 36, no. 52, Dec. 24, 1921, pp. 1022–1031, 15 figs. Discusses especially form and stability, strength and safety, size of crew and comfort of arrangement.

Fokker. The Fokker F4 Passenger Transport Airplane. Aviation, vol. 12, no. 6, Feb. 6, 1922, p. 169, 2 figs. Latest design of A. Fokker is powered with 400-hp. Liberty; carries 10 passengers and hand baggage; high speed, 106 m.p.h.

Helicopters. See HELICOPTERS.

Huff-Daland Biplanes. The Huff-Daland Thick Wing Biplanes. Aerial Age Weekly, vol. 14, no. 22, Feb. 6, 1922, pp. 514–515, 522 and 531, 4 figs. Describes the HD-9A with 10 cylinder Anzani engine, and the "Petrol" HD-8A, a further development of this machine, incorporating OX-5 motor as power plant. See also Aviation, vol. 12, no. 6, Feb. 6, 1922, pp. 161–163, 2 figs.

Mummert Sport. The Mummert "Baby Vamp" Sportplane. Flight, vol. 14, no. 3, Jan. 19, 1922, pp. 40–41, 3 figs. Air-cooled twin-cylinder engine, developing 25-hp. at 1800 r.p.m.

Rib Forms, Strength of. The Strength of Airplane Rib Forms, D. T. Brown and R. J. Diefenbach. Mech. Eng., vol. 44, no. 2, Feb. 1922, pp. 110–111. Description of investigation to determine strength of plywood webs, with lightening holes arranged as in airplane ribs.

AIRSHIPS

Commercial. Traffic Airships With Special Reference to Economy, Walther Leyenstetter. Aerial Age Weekly, vol. 14, nos. 21 and 22, Jan. 30 and Feb. 6, 1922, pp. 495–498 and 520–522, 8 figs. Jan. 30: Flight altitude and efficiency; flight speed; distance flown and useful load. Results so far obtained from practical experiments. Feb. 6: How airships should be constructed in order to fulfill economical conditions of purpose for which it is designed; establishment of an airship line; costs of operation and upkeep. Translated from Zeit. für Flugtechnik und Motorluftschiffahrt.

Goodyear Military. New Goodyear Military Airship, H. T. Kraft, Aviation, vol. 12, no. 4, Jan. 23, 1922, pp. 101–102, 2 figs. Nonrigid; 180,000 cu. ft. capacity; geared propellers driven by two 135-hp. Aeromarine type U-6-D engines; speed, 60 m.p.h.

Rigid. Rigid Airships, Garland Fulton. U. S. Naval Inst. Proc., vol. 47, nos. 10 and 11, Oct. and Nov. 1921, pp. 1565–1591 and 1697–1723, 21 figs. Oct.: Discusses German, British, French and Italian developments. Nov.: Modern types of rigid airships, and developments in United States.

Semi-Rigid vs. Rigid. Semi-Rigid v. Rigid Airships, Umberto Nobile. Flight, vol. 14, no. 4, Jan. 26, 1922, pp. 49–50, 2 figs. Discusses the Roma, Italian semi-rigid, and the German or Zeppelin type, and advantages of Roma over Zeppelin. From Giornale del Genio Civile.

ALCOHOL

Tropical-Plant Fuel Alcohol. Possibilities of the Plant Growth of the Moist Tropics to Furnish Materials for Liquid Fuel, H. N. Whitford. Jl. Indus. & Eng Chem., vol 14, no 2, Feb 1922 pp. 151–152 Reviews possibility of tropics to produce crops of foodstuffs and wood capable of application to manufacture of cellulose and alcohol

ALLOY STEELS

Shock Tests. Shock Tests on Notched Bars (Die Beurteilung der Kerbschlagprobe), H. Moser. Zeit. des Vereines deutscher Ingenieure, vol 66, no 2, Jan. 14, 1922 p. 43. Results of tests for which carbon steels of low and medium tenacity and a nickel steel of high tenacity were used, from each of which standard bars of different widths were made

ALLOYS

Aluminum See ALUMINUM ALLOYS.

Copper. See COPPER ALLOYS

Iron. See IRON ALLOYS.

ALUMINUM

Brittleness of Brittleness Developed in Aluminum and Duralumin by Stress and Corrosion, Henry S. Rawdon, Alexander I Krynitsky and Julius F. T. Berliner Chem & Met Eng vol. 26, no 4, Jan. 25, 1922, pp 151 158 13 figs Aluminum is deeply corroded where impurities lodge between primary grains but if recrystallized, is note embrittled, duralumin is subject to true intercrystalline embrittlement, but intensified by corrosion and stress

Flasks, Manufacture of. Manufacture of Aluminum Flasks (Herstellung von Aluminiumflaschen), Karl Rieger Werkstattstechnik, vol. 16, no. 1, Jan. 1, 1922, pp 1–3, 24 figs. Describes process of manufacture from original aluminum sheet to finished product.

ALUMINUM ALLOYS

Aluminum-Silicon. A New Light Alloy (Silumin, eine neue Leichtlegierung), J Czochalralski. Zeit. für Metallkunde, vol 13, no. 14, Nov. 1921, pp. 507–510, 12 figs. Describes new alloy called silumin, consisting of aluminum and silicon refined through certain additions. It is claimed that its structure and technological properties are superior to similar casting alloys, and its use greatly increases possibilities of employing light alloys for structural purposes.

Bronzes. Macrography and the Pouring of Aluminum Bronzes (Emploi de la macrographie pour la mise au point de la coulée du bronze d'aluminium), J. Galibourg and A. Brizon. Révue de Métallurgie, vol. 18, no. 12, Dec. 1921, pp. 780–786, 15 figs. Difficulties of pouring, especially pipe; use of coolers, their position, etc.

Die Casting. Aluminum and Its Alloys—VI, F. A. Livermore. Metal Industry (Lond.), vol. 20, no. 2, Jan. 13, 1922, pp. 25–29, 7 figs. Deals with aluminum alloy die casting.

AMMONIA

Synthesis of. Synthesis of Ammonia (La recherche scientifique, ses applications a l'industrie et la synthèse industrielle de l'ammoniaque), Georges Claude. Révue Générale des Sciences, vol. 32, nos. 19 and 20, Oct. 15 and 30, 1921, pp. 534–543 and 570–581, 10 figs. Oct. 15: Difficulties of scientific research, its resources, etc.; manufacture of hydrogen, chlorine, helium, neon, etc. Oct. 30: Describes equipment and operations at Montereau Ammonia Extraction works working at a pressure of 1,000 atmos

AMMONIA COMPRESSORS

Starterless Induction Motors for. Starterless Induction Motors for Ammonia Compressors, J. Lebovici. Ice & Refrigeration, vol. 62, no. 1, Jan. 1922, pp. 24–25. Describes starterless motor, combining favorable characteristics of squirrel-cage and slip-ring types, making an ideal drive for ammonia compressors using up to 150 hp. Paper read before Nat. Assn. Practical Refrig. Engrs.

AUTOMOBILE ENGINES

Air-Cooled. Air-Cooling Systems: Past, Present and Future. Autocar, vol. 28, no. 1369, Jan. 14, 1922, pp. 47–50, 7 figs. Gives concise summary of the various points for and against use of air-cooled engines for small cars, directions in which developments must tend.

Single-Cylinder Air-Cooled Sleeve-Valve Motor-Cycle Engine Engineering, vol. 113, no. 2924, Jan. 13, 1922, pp. 44–45, 9 figs. Details of Barr and Stroud engine with 70-mm. bore and 90.5-mm. stroke, giving capacity of 349 cc., said to be first application of this type of engine to automobile work.

Braking Tests. Braking Tests with Automobile Engines (Kurze Anleitung zu Bremsversuchen an Kraftwagenmotoren), A. Heyne Allgemeine Automobil-Zeitung, vol. 22, nos. 19 and 20, May 7 and 14, 1921, pp. 37–39 and 36–38, 1 fig. Notes on determination of brake power, torsional moments, mean piston pressures, fuel consumption, and pumping efficiency. Gives example of how to conduct tests.

Cylinders. Cylinders for the Mack Motor, Fred. H. Colvin. Am. Mach., vol. 56, no. 5, Feb. 2, 1922, pp. 173–174, 7 figs. Fixtures, trams and gages for locating cylinder from bore. Inspection methods which secure results. Volume of compression chamber tested by liquid gage.

Operations on the Cylinders of the Wills Sainte Claire, Fred H. Colvin. Am. Mach., vol. 56, no. 5, Feb. 9, 1922, pp. 216–218, 12 figs. Closed end cylinders require special tools for machining combustion chambers. Special boring machine with inclined spindles. Heat-treatment removes strains.

Peugeot-Tartrais Direct-Injection. Peugeot To Produce Automotive Injection Engine, W. F. Bradley. Automotive Industries, vol. 46, no. 6, Feb. 9, 1922, pp. 269–271, 11 figs. Said to be capable of using any liquid fuel; two-stroke cycle, develops 50 hp at 1250 r p m.; weight, 550 lb.; uses 0 397 lb. fuel per hp hr at full load and 0.184 lb at quarter load See also Commercial Vehicle, vol 26, no. 1, Feb. 1, 1922, p 31, 3 figs

The Peugeot-Tartrais Engine Autocar, vol. 48, no 1370, Jan. 21, 1922, pp. 116 117, 8 figs. A 2 cylinder, 2-cycle, direct-fuel-injection power unit weighing 11 lb. per hp., allowing a wide choice for fuels

Two-Stroke Cycle. A New Two-Stroke Engine. Autocar, vol 28, no. 1369, Jan. 14, 1922, pp. 73 74, 2 figs Describes three-cylinder two-cycle Wege motor Each lower cylinder acts as a compressor for an adjacent upper cylinder, in which power impulse takes place.

The Two-Stroke Motor Car Engine, F. W. Lanchester and R H. Pearsall. Engineering, vol. 133, nos 2925 and 2926, Jan. 20 and 27, 1922, pp 90 92 and 122 121, 16 figs. Investigation of principal factors controlling performance of such engines. Paper read before Instn. Automobile Engrs.

AUTOMOBILES

Alfa-Romeo. The 35–50 Hp. Alfa Romeo Chassis. Automobile Engr., vol. 12, no. 159, Jan. 1922, pp. 2 6, 9 figs. Built by Nicola Romeo & Co., Milan. Main features are ease of inspection and facilities for repairs or replacements.

Berliet. The 20 hp. and 25 hp. Berliet Cars Autocar, vol. 28, no. 1369, Jan. 14, 1922, pp. 59 60, 5 figs. Monobloc four-cylinder engines; unit principle of construction.

Bugatti and Hillman. Some 1922 Car Features. Auto, vol. 27, no. 2, Jan. 12, 1922, pp. 29 32, 13 figs Particulars of new 16-valve 23.8-hp. straight-eight Bugatti, and the 11-hp. Hillman car, in chassis of which steel stampings are largely used.

Electric. A Modern Electric Passenger Vehicle, Herbert Chase. Automotive Industries, vol. 46, no 6, Feb 9, 1922, pp. 265–268, 6 figs. Describes new car of Ranch & Lang; weight of battery approximately 830 lb., distributed front and back; maximum speed, 28 m.p.h. in sixth controller position, and 25 m.p.h. in fifth.

Elgin. Elgin Chassis Has Been Completely Redesigned, P. M. Heldt. Automotive Industries, vol. 46, no. 3, Jan. 19, 1922, pp. 134–135, 4 figs. New model 700 is fitted with 6-cylinder valve-in-head type special Falls engine, new single-plate clutch, larger fan and radiator and new hand brake on gear set.

Front-Axle Stubs. Machining Automobile Front Axle Stubs, F. Hickling. Machy. (Lond.), vol. 19, no. 487, Jan. 26, 1922, pp. 497–499, 7 figs. Discusses layout for a particular type of stub, which has been in use for over two years, on a production of 50 to 100 pairs per week.

Frontenac 4-Cylinder. New Four-Cylinder Car Has Brakes on All Wheels, J. Edward Schipper. Automotive Industries, vol. 46, no. 1, Jan. 5, 1922, pp. 5–6, 4 figs. Describes new Frontenac car designed by Chevrolet and Van Ranst. Chain-driven overhead camshaft and location of electrical units alongside gear set gives a clean-appearing power plant.

Gear Boxes. Notes on Motor Car Gearboxes, H. F. L. Orcutt. Automobile Engr., vol. 12, no. 159, Jan. 1922, pp. 22–30, 7 figs. Discusses principal defects relating to design, workmanship and material. Describes gear-tooth grinding process. Costs of production. Paper read before Instn. Automobile Engrs.

Manufacture. Cars in the Making. Autocar, vol. 47, nos. 1365, 1366 and 1367, Dec. 17, 24 and 31, 1921, pp. 1254–1255, 1289–1291 and 1341–1343, 18 figs. Dec. 17: Practical working out of designs by experimental work. Dec. 24: Describes methods by which raw materials are worked up into forms suitable for economic processes of machine-shop production. Dec. 31: Deals with preparation of tools and jigs, and explains methods of using lathe to secure interchangeability of parts.

Napier. The 40–50 Hp. Napier Chassis, Automobile Engr., vol. 11, no. 158, Dec. 1921, pp. 430–437, 20 figs. Describes frame, engine (6-cylinder block), clutch (single-plate), gear box, foot brake, transmission and rear axle, front axle and steering, etc.

Repair-Shop Practice. Automobile Repair Shop Practice. Machinery (Lond.), vol. 19, no 485, Jan. 12, 1922, pp. 445–447, 4 figs. Describes methods and equipment commonly employed in automobile repair shop practice.

Service Equipment. Automotive Service Methods and Equipment, Howard Campbell. Am. Mach., vol. 56, no. 4, Jan. 26, 1922, pp. 125–127, 11 figs. Tools used for servicing Hudson and Essex Cars. Fixtures for testing and straightening. Attachments for lapping pistons and cylinders.

Wolseley Works. Famous British Works. Eng. Production, vol. 4, no. 70, Feb. 2, 1922, pp. 98 100, 6 figs. Describes works of Wolseley Motors, Ltd., Birmingham, engaged at present in manufacture of the 10-hp. Wolseley, the Wolseley "fifteen," and the 20-hp. car de luxe.

AVIATION

French Civil Transport. French Progress in Civil Air Transport, M. de Lavergne. Aviation, vol. 12, no. 6, Feb. 6, 1922, pp. 170–171. In three years French merchant air fleet expanded from 46 airplanes to 258, all of which are used on regular transport services.

Pilot and Aircraft Registration. Underwriters' Laboratories Aviation Record. Aviation, vol. 12, no. 6, Feb. 6, 1922, pp. 160–161, 1 fig. Gives first list of American pilot and aircraft registration, prepared at request of Nat. Aircraft Underwriters Assn., members of which are hereafter to require registration of aircraft which they insure against fire, theft, collision, stranding and sinking, etc.

B

BEARINGS, BALL

Design and Performance. Ball and Roller Bearings. Their Design and Performance, A. W. Macaulay. Engineering, vol 113, no 2925, Jan. 20, 1922, p. 87, 6 figs Points out that principal conditions which bearing must fulfill are (1) capacity for taking combined radial and thrust load, (2) self-contained unit having no loose parts, and without necessity of any adjustment, (3) high fatigue limit; (4) lowest possible friction; (5) absence of vibration. (Abstract.) Paper read before Instn. Engrs. & Shipbuilders in Scotland.

BLAST FURNACES

Hot-Blast Stove Rating. Hot Blast Stove Rating, F. H. Willcox. Blast Furnace & Steel Plant, vol. 10, no. 1, Jan. 1922, pp. 29 32. Actual test data showing effectiveness of hot blast stove equipment as applied to a 600-ton blast furnace.

Rebuilt. Rebuilds Stack on Historic Site, Richard Peters, Jr. Iron Trade Rev., vol. 70, no. 5, Feb. 2, 1922, pp. 325 328, 5 figs. Furnace succeeding famous Warwick unit has been replaced, work involving construction of new stack, top and downcomers. New blast furnace has skip bridge with independent shear leg support.

BLOWERS

Roots. Hints on Repairing Roots Blowers, F. R. Parsons. Mech. World, vol. 71, no. 1830, Jan. 27, 1922, pp. 64–65, 3 figs. Maintenance and efficient upkeep of Roots pressure blowers; sources of trouble and suggested remedies; lubrication and belt troubles.

Turbo. Turbo-Boosters and Exhausters for Town Gas. Engineering, vol. 113, no. 2926, Jan. 27, 1922, pp. 105 106, 8 figs. partly on p. 108. Deals with some of later developments by The Bryan Donkin Co., Ltd., Chesterfield, England, particularly the Rateau turbo-blowers and fans.

BOILER EXPLOSIONS

Causes. A New Boiler Explosion, G. W. Atkinson. Power, vol. 55, no. 6, Feb. 7, 1922, pp. 206–207, 3 figs. Leakage near flange of bumped head led to investigation which disclosed dangerous crack. Breathing of head probable cause.

BOILER OPERATION

CO_2 Values, Interpreting. Effect of Coal on Excess Air in Boiler Operation, Hugh R. Carr. Power Plant Eng., vol. 26, no. 2, Jan. 15, 1922, pp. 112–114, 2 figs. Considerations to be taken into account in interpreting CO_2 values with different kinds of coal.

Efficient. The Necessity for and Savings Possible with Better Boiler-Room Operation. C. W. De-Forest. Power, vol. 55, no. 4, Jan. 24, 1922, pp. 139 141, 3 figs. Deals with cost of fuel, organization, boiler-room instruments and records. (Abstract.) Paper read before Stoker Mfrs. Assn.

BOILER PLANTS

Ford Motor Co. Power House. A Large American Power Plant. Eng. Production, vol. 4, nos. 68 and 69, Jan. 19 and 26, 1922, pp. 61–64 and 85–88, 6 figs. Details of boiler equipment of Ford Motor Co. (Abstract.) Paper presented to Engrs. Soc. West. Pa., by George T. Ladd, with contributions by H. T. Savage and J. R. Le Valley.

Valuation. Valuation of the Boiler Plant, Allen F. Brewer. Combustion, vol. 6, no. 2, Feb. 1922, pp. 84–88. Notes on unit cost data; overhead charge estimation; salvage and service values.

BOILERS

Capacities. Boiler Capacities Obtainable per Cubic Foot of Furnace Volume, T. B. Stillman. Power, vol. 55, no. 5, Jan. 31, 1922, pp. 171–173, 3 figs. Detailed test results on boilers operating at as high as 658.9 per cent rating. In one case 2285 lb. of oil was burned per hr. per burner. Paper presented before Assn. Edison Illuminating Companies.

High-Pressure. High-Pressure Steam up to 60 Atmos. for Power and Heat Generation (Hochdruckdampf bis zu 60 at in der Kraft- und Wärmewirtschaft), O. Hartmann. Elektrotechnische Zeit., vol. 43, no. 2, Jan. 12, 1922, pp. 45–47, 2 figs. Describes high-pressure boiler for 60 atmos. developed by Wilhelm Schmidt, which can safely generate steam at this atmosphere and up to temperature of 480 deg. It has a grate surface of 1.42 sq. m. and total heating surface, including superheater, of 72 sq. m. and has generated steam up to 1340 kg. per hr. (Abstract.) Address and discussion before Soc. German Engrs.

Locomotive. See LOCOMOTIVE BOILERS.

Marine. See MARINE BOILERS.

BOILERS, WATER-TUBE

Kestner. Developments in Power Station Design. Engineer, vol. 133, no. 3446, Jan. 13, 1922, p. 41, 2 figs. Describes Kestner water-tube boiler which, it is claimed, has acquired favor in France, Belgium, Denmark, Germany, Russia and the Argentine.

Marine. A New Water-Tube Boiler For Merchant Ships. Mar. Engr. & Naval Architect, vol. 45, no. 532, Jan. 1922, pp. 10–11 and 40, 2 figs. Describes the Hawthorn-Armstrong patent boiler in which an effort has been made to combine in one unit a steam generator suitable for use in merchant ships and to provide a high degree of superheat.

BORING MACHINES

Machining Locomotive Brasses. Machining Locomotive Brasses on Boring Mill, J. H. Moore. Can. Machy., vol. 27, no. 2, Jan. 12, 1922, pp. 17-19, 9 figs. Importance of proper fixtures if maximum production is to be attained. Describes machining of a 9-in. globe valve.

BRAKES

Freight-Train Vacuum. Vacuum Brake Trials on the Great Northern Railway, Henry Fowler. Ry. Gaz., vol. 36, no. 3, Jan. 20, 1922, pp. 87-88 and 100, 3 figs. Results of trials in connection with application of vacuum brake for long freight trains carried out between Peterborough and Firsby. Paper read before Instn. Civil Engrs.

Railway Brakes for Heavy Traffic. Engineering, vol. 113, no. 2924, Jan. 13, 1922, p. 43. Abstracts of two papers read before Instn. Civ. Engrs., entitled, Control of Trains Considered in Relation to Increase of Weight and Speed, Combined with Reduced Headway, by Alan Wood Rendell; and Trials in Connection with the Application of the Vacuum Brake for Long Freight Trains, Henry Fowler and Herbert N. Gresley.

BRASS

British Industry. Modern Developments in the British Brass Industry, Ernest T. Smith. Can. Chem. & Metallurgy, vols. 5 and 6, nos. 12 and 1, Dec. 1921 and Jan. 1922, pp. 345-348 and 8-12. Discusses extent to which existing scientific and technical knowledge has been utilized in British brass industry as a whole and describes development resulting from its utilization. Melting and foundry practice; electric furnaces; extrusion of brass; hot pressing and forging; rolling-mill practice; annealing; composition of brasses and special alloys; research and its organization. Paper read before Am. Electrochem. Soc.

Rod. Modern Methods of Making Brass Rod. Brass World, vol. 18, no. 1, Jan. 1922, pp. 3-4, 9 figs. partly on pp. 5-7. Describes development of extrusion process and present-day extrusion machines.

Season Cracking. Experiences of Season Cracking during the Great War, Owen W. Ellis. Faraday Soc. Trans., vol. 17, part 1, no. 49, Dec. 1921, pp. 193-200. Points out success which attended ordnance factories' practice of low-temperature annealing.

The Prevention of Season Cracking in Brass by the Removal of Internal Stress, H. Moore and S. Beckinsale. Faraday Soc. Trans., vol. 17, part 1, no. 49, Dec. 1921, pp. 162-192, 22 figs. Reduction of stress by low-temperature annealing was studied in 70-30 brass cold-rolled to 120, 160, and 200 Brinell hardness, in elastically bent test-strips of each hardness, initally stressed to 11, 17, and 22 tons per sq. in. maximum tension at surface. Results are presented in tables and summarized.

Spontaneous Cracking. The Spontaneous Cracking of the Necks of Small Arm Cartridge Cases, W. C. Hothersall. Faraday Soc. Trans., vol. 17, part 1, no. 49, Dec. 1921, pp. 201-208, 6 figs. Said to be due to existence of stress in neck of case arising in some operation or operations subsequent to semi-annealing.

BRONZE

Manganese. Manganese Copper, Jesse L. Jones. Metal Industry (N. Y.), vol. 20, no. 1, Jan. 1922, p. 7. Discusses its use in manufacture of manganese bronze, and methods of obtaining best results.

C

CABLEWAYS

Aerial. Automatic Aerial Tramway. Rock Products, vol. 25, no. 3, Feb. 11, 1922, pp. 26-27, 2 figs. Tramway at Clinchfield Products Corp. operating a barytes mine at Evington, Va., is reversible; hauls both coal and ore.

Track Cables. Tensions in Track Cables and Logging Skylines, Samuel Herbert Anderson. University of Washington Eng. Experiment Station Bul., no. 13, June 1921, 27 pp., 5 figs. Deals with problem of catenary loaded at one point. Equations are derived and properties of such catenary discussed. It is shown how tensions may be computed and what the condition is for maximum tension.

CAR WHEELS

Flange Lubrication. Automatic Lubricating Apparatus for Flanges of Wheels of Electric Cars (Appareil de graissage automatique pour les boudins des roues de voitures automotrices électriques), H. Strehler. Bul. Technique de la Suisse Romande, vol. 47, no. 26, Dec. 24, 1921, pp. 301-303, 5 figs. Describes apparatus for railroad use and one for street cars for lubricating when negotiating curves, without dropping oil on rails.

Machining. Correct Machining and Mounting of Wheels and Axles and the Necessity for Carefully Measuring Axles Removed from Cars so that Proper Credits can be Allowed, Chas. Petran. Official Proc. of Car Foremen's Assn. of Chicago, vol. 17, no. 3, Dec. 1921, pp. 16-29 and (discussion) 30-57, 3 figs. Discusses boring of cast iron wheels; fitting wheels to axles; wheel mounting pressure and its automatic registration; instructions to guard against wrong inspection of axles; rolled-steel wheels; etc.

Manufacture. Wheels for Railway Rolling-Stock. Ry. Gaz., vol. 35, no. 27, Dec. 30, 1921, pp. 1000-1002, 6 figs. Describes new process of manufacturing wheel centers of the solid disk type.

Steel-Tired. Cast-steel and Steel-tyred Wheels, H. W. Mellor. Machinery (Lond.), vol. 19, no. 486, Jan. 19, 1922, p. 479, 4 figs. Suitable thickness for steel tires, and rims for steel wheels.

Sandberg Sorbitic Steel for Tyres. Ry. Gaz., vol. 35, no. 27, Dec. 30, 1921, pp. 991-992 and 999, 6 figs. partly on p. 993. Improvements due to Sandberg process which add considerably to capacity of rolling stock and reduce occupancy of repair shops. See also Ry. Engr., vol. 43, no. 504, Jan. 1922, pp. 16-17 and 35, 6 figs.

CARS

Reclaiming Metal Roof Sheets. Reclaiming Sheets of Outside Metal Car Roofs. Ry. Age, vol. 72, no. 4, Jan. 28, 1922, pp. 275-276, 4 figs. Savings in car-repair costs are result of moderate expenditures for facilities.

CASE-HARDENING

Charcoal Carbonization. Carbonization With Wood Charcoal, H. Schagrin. Am. Soc. for Steel Treating Trans., vol. 2, no. 4, Jan. 1922, pp. 331-335 and (discussion) 335-338, 12 figs. Discusses tests made with drop forgings of acid bessemer steel which showed that charcoal was cheap and satisfactory casing material.

CAST IRON

Hardness Tests. Mechanical and Elastic Properties of Cast Iron and the Use of the Ball Hardness Test (Caractéristiqués méchaniques ét élastiques des fontes et utilisation de l'essai à la bille), Albert Portevin. Révue de Métallurgie, vol. 18, no. 12, Dec. 1921, pp. 761-779, 19 figs. Discusses tests required by French artillery for steeled iron shells, including elongation, compression, and hardness.

Malleable. American Malleable Cast Iron, H. A. Schwartz. Iron Trade Rev., vol. 70, nos. 5 and 6, Feb. 2 and 9, 1922, pp. 335-341 and 410-411, 14 figs. Mechanical effects of plastic deformation.

Malleableizing of White Cast Iron, Arthur Phillips and E. S. Davenport. Am. Inst. Min. & Metallurgical Engrs. Trans., no. 1117-S, 1922, 23 pp., 49 figs., and (in abstract) Min. & Metallurgy, no. 181, Jan. 1922, pp. 31-32. Presents data and observations resulting from series of experiments dealing with heat treatment and microstructure of commercial white cast iron and its derivative, malleable iron.

The Molding of Malleable Pig Iron (Aus der Formereitechnik des Tempergusses), Rudolf Stotz. Giesserei-Zeitung, vol. 19, no. 1, Jan. 3, 1922, pp. 1-5, 14 figs. Discusses difficulties encountered in molding of malleable iron due to its possessing strong shrinking and brittle properties, and makes suggestions for overcoming these difficulties.

Synthetic. Manufacture of Synthetic Cast Iron in the Electric Furnace, W. L. Morrison. Chem. & Met. Eng., vol. 26, no. 7, Feb. 15, 1922, pp. 312-316. Production on Pacific coast; detrimental effects of excessive dry slags; comparative operating costs.

Synthetic Cast Iron, Made in California, Larry J. Barton. Chem. & Met. Eng., vol. 26, no. 6, Feb. 8, 1922, pp. 270-271. Discusses production of iron from steel scrap and gives particulars of electric-furnace operations.

CASTINGS

Automobile. British Motor Castings Methods—III, Ben Shaw and James Edgar. Foundry, vol. 50, no. 3, Feb. 1, 1922, pp. 103-107, 23 figs. Making of patterns and coreboxes for a typical crankcase casting; detail and reasons for methods recommended.

CENTRAL STATIONS

Superpower, France. The Superpower Station at Gennevilliers (La supercentrale de Gennevilliers), L. D. Fourcault. Technique Moderne, vol. 13, no. 12, Dec. 1921, pp. 525-527, 9 figs. partly on supp. plate. Describes civil engineering work, including foundations, especially for machines.

CHIMNEYS

Calculation. Simplified Chimney Calculation (Vereinfachte Schornstein-Berechnung), Otto Hoffmann. Feuerungstechnik, vol. 10, nos. 6, 7 and 8, Dec. 15, 1921, Jan. 1 and 15, 1922, pp. 53-56, 65-68 and 79-82, 2 figs. Simple method is developed for determining, for all sizes and fuels, the correct chimney dimensions. Comparison of ten different methods of calculation.

CHROME-NICKEL STEEL

Krupp Rustproof. Krupp Rustproof Steel, Fritz Huth. Mech. Eng., vol. 44, no. 2, Feb. 1922, pp. 120-121. Developed as result of investigations carried out at establishment during years 1909 to 1914 on corrosion of steel, and belonging to class of chrome-nickel steels. Translated from Metall-Technik, vol. 47, no. 17, Nov. 1, 1921, p. 123.

CHROME STEEL

Heat Treatment. The Heat Treatment of Special Steels in General and with Particular Reference to Chrome Steels (Ueber die Wärmebehandlung der Sonderstähle im allgemeinen und der Chrosmtähle im besonderen), E. Maurer and T. Hohage. Stahl u. Eisen, vol. 42, no. 2, Jan. 12, 1922, pp. 59-61. Deals with heat treatment of the steels, with special regard to notch test and tensile strength. (Abstract.) Mitteilung K.-W.-Inst. f. Eisenforschung, vol. 2, pp. 91-105.

Properties. Chromium Steels and Irons, Leslie Aitchison. Automobile Engr., vol. 11, no. 158, Dec. 1921, pp. 451-458, 5 figs. Discusses the three main advantages of alloy steels as against carbon steels, viz., high tensile strength, high toughness, ease in hardening and homogeneity in resulting product. Mechanical properties of chromium steels and irons. Paper read before Instn. Automobile Engrs.

CLUTCHES

Pomini Friction. The Pomini Friction Clutch. Engineering, vol. 113, no. 2925, Jan. 20, 1922, pp. 70-71, 32 figs. Partly on supp. plate. Describes clutch constructed by Societa Anonima Luigi Pomini, Castellanza, Italy, known as "Superpotente," and intended to transmit 3000 hp. at 330 r.p.m. It is suitable for coupling Diesel engines to propeller shafts in submersible boats. Several were delivered to Italian Navy for war service.

COLD STORAGE

Meat and Fish. On the Freezing of Food-Stuffs, Martin Krause. Eng. Progress, vol. 3, no. 1, Jan. 1922, pp. 7-10, 6 figs. Discusses investigations carried out in Germany regarding process of freezing pork, beef and fish.

COLUMNS

Buckling. Buckling of Elastic Structures. Am. Soc Civ. Engrs. Proc., vol. 48, no. 1, Jan. 1922, pp. 103-110, 1 fig. Discussion by George Paaswell of paper by H. M. Westergaard published in same journal (Nov. 1921.)

COMPRESSED AIR

High-Pressure Handling. Methods of Handling Very High Pressures, P. W. Bridgman. Compressed Air Mag., vol. 27, no. 1, Jan. 1922, pp. 17-19, 5 figs. Explains methods of packing pistons and joints in order to obtain pressures up to 500,000 lb. per sq. in.

CONDENSERS, STEAM

Surface. Measurement of Surface-Condenser Leakage by Electrolytic-Conductivity Method, Earl A. Keeler. Power, vol. 55, no. 4, Jan. 21, 1922, pp. 126-128, 6 figs. Discusses difficulties in applying electrical methods to measuring condenser leakage, and how some of these difficulties have been overcome. How measurements are made. Factors affecting accuracy of measurements.

CONNECTING RODS

Side Thrust Due to Obliquity. Side Thrust due to Obliquity of the Connecting Rod in a High Speed Reciprocating Engine, Tetsuji Sugihara. Technology Reports of Tôhoku Imperial University, vol. 2, no. 3, 1921, pp. 17-26, 7 figs. Writer seeks to obtain expression for side thrust due to obliquity of connecting rod, and expresses it graphically when these effects are taken into account.

CONVERTERS

Bessemer Side-Blown. New Side-Blown Bessemer Converter, T. Levoz. Mech. Eng., vol. 44, no. 2, Feb. 1922, p. 122, 1 fig. Historical account of development, with criticism of various types. Describes type developed by author and points out its advantages. Translated from Fonderie Moderne, no. 10, Oct. 1922, pp. 284-290, 3 figs.

CONVEYORS

Overhead System. Double-Rail Overhead Conveying System, G. L. Lacher. Iron Age, vol. 109, no. 6, Feb. 9, 1922, pp. 409-410, 5 figs. Safeguards against track-jumping. Trolleys have two, four or eight wheels, and can carry load of 3000 lb.

Steel Belt. Swedish Steel Belt Conveyors, Harry Carlson. Iron Age, vol. 109, no. 5, Feb. 2, 1922, pp. 321-323, 7 figs. Especially adapted to hot and sticky materials, which cannot be carried on rubber or fabric belts. Lower power cost.

Types. Conveying and Elevating Machinery, Gardner Mitchell. Eng. & Indus. Management, vol. 7, no. 4, Jan. 26, 1922, pp. 109-114, 6 figs. Deals with spiral or worm, screw, paddle, belt, gravity-bucket, tray, slat, push-plate or scraper, and drag-link conveyors; and chain, belt and bucket elevators. Paper read before (British) Instn. Mech. Engrs.

COOLING TOWERS

Recooling. The Recooling of Water in Self-Ventilating Tower Coolers (Ueber die Wasserrückkühlung mit selbstventilierendem Turmkühler), Carl Geibel. Forschungsarbeiten auf dem Gebiete des Ingenieurwesens, no. 242, 1921, 98 pp., 128 figs. Tests carried out on experimental plant designed by author, in which different types of cooling towers and spraying nozzles were temporarily installed. Tests were conducted under widely differing atmospheric conditions with varying volumes of water and heat units. Results are given in equations indicating properties of the different cooling plants, and permitting comparisons between recirculated and fresh-water operation.

COPPER ALLOYS

Phosphor-Copper. Phosphor Copper, Jesse L. Jones. Metal Industry (N. Y.), vol. 20, no. 1, Jan. 1922, pp. 6-7. Discusses its increased use as a deoxidizer, and methods of obtaining best results.

CORROSION

Causes and Prevention. What It Pays to Know About Corrosion, G. A. Van Brunt. Factory, vol. 27, nos. 5 and 6, Nov. and Dec. 1921, pp. 621-623 and 763-766, 1 fig. and vol. 28, nos. 1 and 2, Jan. and Feb. 1922, pp. 49-52, 4 figs. and pp. 172-174. Nov.: Causes and best methods of preventing corrosion. Dec.: How coatings of various metals, variously applied, protect iron and steel. Jan.: Where to use coatings of paint and japan. Feb.: Oxides and phosphates: Where to use them as protective coatings.

Condenser Tubes. Results Achieved by the Corrosion Committee British Institute of Metals, Ernest E. Thum. Chem. & Met. Eng., vol. 26, no. 7, Feb. 15, 1922, pp. 301-306, 9 figs. Discusses failure of brass condenser tubes in marine service, caused by lodgment of solids which trap corrosive substances formed during process of slow general thinning.

Iron Pipe. Increasing the Safety against Rust and the Mechanical Resistivity of Iron and Iron Pipes (Fördern der Rostsicherheit und mechanischen Widerstandsfähigkeit von Eisenröhren bzw. Eisen), B. Haas. Zeit für die gesamte Giessereipraxis, vol. 42, nos. 10 and 11, Mar. 5 and 12, 1921, pp. 141–143 and 135–137. Discusses preventive measures.

Zinc and Tin. Corrosion Patterns on Cold-Worked Tin and Zinc, Henry S. Rawdon, Alexander I. Krynitsky and Julius F. T. Berliner. Chem. & Met. Eng., vol. 26, no. 5, Feb. 1, 1922, pp. 212–213, 3 figs. Properties of tin and zinc after deep corrosion.

COST SYSTEMS

Relation to Production. The Costing System and Its Relation to Production, G. H. Hales. Eng. & Indus. Management, vol. 7, nos. 1, 2, 3 and 4, Jan. 5, 12, 19 and 26, 1922, pp. 17–19, 31–34, 63–65, 5 figs. Jan. 5: Writer demonstrates value of coördination between costs and production department. Jan. 12: Questions relating to "productive hours," departmental expenses and establishment charges. Feb. 19: Premium bonus tickets. Jan. 26: Outlined system in practice. See also Eng. Production, vol. 4, nos. 66 and 67, Jan. 5 and 12, 1922, pp. 7–10 and 31–34, and (discussion), no. 68, Jan. 19, 1922, pp. 66–67. Paper read before Instn. Production Engrs.

CRANES

Electric Runabout. An Electric Runabout Crane. Eng. Production, vol. 4, no. 70, Feb. 2, 1922, p. 115, 1 fig. Describes trackless mobile cranes built by Ransomes, Sims & Jefferies, Ltd., Ipswich, England.

Hoisting Motors for. New Control for Lowering Speed on Three-Phase Cranes (Eine neue Senkbremsschaltung für Krane in Drehstromanlagen), Chr. Ritz. Siemens-Zeit., vol. 1, no. 12, Dec. 1921, pp. 476–480, 3 figs. Instead of one three-phase hoisting motor, two half-size motors, rigidly connected, are used. Hoisting is done with both motors in parallel, as if they were a single unit, but in lowering a load the two motors are energized in opposite torque sense. Characteristic operating curves of such a hoisting motor are given.

Locomotive. Increasing the Scope of Locomotive Cranes. Ry. Age, vol. 72, no. 6, Feb. 11, 1922, pp. 363–367, 4 figs. Experiences of Lehigh Valley demonstrates that a wide range of work can be handled advantageously.

CRANKCASES

Machining. Machining the Mack Crankcase, Fred H. Colvin. Am. Mach., vol. 56, no. 7, Feb. 16, 1922, pp. 256–257, 10 figs. Describes unusual milling cutter. Zylol used for detecting cracks. Methods of boring and reaming. Gages for final inspection.

CRANKSHAFTS

Forging. Radiagraph Aids in Forging Crankshafts, Fred E. Rogers. Forging & Heat Treating, vol. 8, no. 1, Jan. 1922, pp. 26–28, 9 figs. Mechanically operated cutting torches for cutting heavy crankshafts, for preliminary cuts and cutting after cranks have been twisted through 120 deg.

Machining. A Crank Arm Turning Machine, P. M. Heldt. Automotive Industries, vol. 46, no. 2, Jan. 12, 1922, pp. 77–78, 5 figs. Describes device which simultaneously turns non-circular contours of all of the arms of an engine crankshaft.

CUTTING TOOLS

Diamond. Manufacture and Use of Diamond Cutting Tools, Ellsworth Sheldon. Am. Mach., vol. 56, nos. 4 and 6, Jan. 26 and Feb. 9, 1922, pp. 140–142, 5 figs. and 210–212, 8 figs. Jan. 26: Polishing or lapping the stone; wire-drawing dies. Feb. 9: Diamonds for drawing dies; methods of reducing diamonds to dust.

D

DIE CASTING

Methods. How Diecastings Are Produced, Herbert Chase. Automotive Industries, vol. 46, no. 1, Jan. 5, 1922, pp. 21–25, 8 figs. Describes methods followed and various types of die-casting machines employed. Characteristics of various alloys.

Pressure. Pressure Die Casting. Metal Industry (Lond.), vol. 20, no. 1, Jan. 6, 1922, pp. 1–3, 2 figs. Advantages of die casting over other forms of manufacture. Discusses half-round bearing dies.

DIESEL ENGINES

Compressors for. The Use of Compressed Air in Diesel Engined Ships, William Reavell. North-East Coast Instn. Engrs. & Shipbuilders, advance paper no. 3222-P, for meeting Jan. 27, 1922, 16 pp., 26 figs. In author's opinion, main compressor of marine Diesel engines is usually made needlessly large, and better efficiency in operation and saving in cost, weight, power, etc., would be obtained if capacity were reduced. Discusses functions and construction of auxiliary compressors.

Deutz Compressorless. The New Deutzer Compressorless Diesel Engine (Der neue Deutzer kompressorlose Dieselmotor), H. Schneider. Oel- u. Gasmaschine, vol. 18, no. 12, Dec. 1921, pp. 186–188, 4 figs. Notes on design, operation and advantages of new compressorless horizontal Diesel engine, which can be operated with all heavy oils, including tar oil.

Flexibility. Diesel-Engine Flexibility, W. S. Burn. North-East Coast Instn. Engrs. & Shipbuilders advance paper, no. 3228-P, for meeting Jan. 6, 1922, 40 pp., 22 figs. Investigation of flexibility of Diesel engine with view to its application to direct-driven Diesel locomotive.

Fuel Injection. Devices for Injection of Fuel Oil with Use of Injection Air in Diesel Engines without Regulation of the Discharge Openings (Vorrichtungen zum Einspritzen von Brennöl unter Verwendung von Einblaseluft bei Dieselmaschinen ohne Regelung der Ausspritz-Querschnitte). Wirtschaftsmotor, no. 7, July 1921, pp. 19–21. Controversy between Max Lindemann and F. E. Bielefeld relative to article by Lindemann published in same journal (no. 4, p. 17) and article by Bielefeld published in Oel- u. Gasmaschine (no. 1, p. 1).

Manufacture. Production of Cylinders, Pistons and Segments for Combustion Engines (Fabrication des cylindres, pistons et segments des moteurs à combustion). L'Ouvrier Moderne, vol. 4, no. 10, Jan. 1922, pp. 407–410, 2 figs. Choice and treatment of metals used in manufacture for Diesel engines.

Marine, Nobel 1600 B.H.P. Nobel-Diesel Marine Engine, George J. Steinheil. Engineer, vol. 133, nos. 3448 and 3449, Jan. 27 and Feb. 3, 1922, pp. 91–93, 5 figs. partly on p. 102, and 126–128, 6 figs. Describes latest product of Swedish Nobel-Diesel Co., Ltd., at Nynashamn. Engine is of two-cycle single-acting direct reversible crosshead marine type with 2000 i.hp. and giving mechanical efficiency of 80 per cent. Result of official trials.

The Two-Stroke Diesel Engine for Ship Drive (Die Zweitakt-Dieselmaschine im Schiffsbetrieb), H. Flasche. Zeit. des Vereines deutscher Ingenieure, vol. 66, no. 3, Jan. 21, 1922, pp. 53–59, 33 figs. Design and operation of a new 2000-hp. engine with port valve gear, constructed by the Nobel-Diesel Corp., Nynashamn, Sweden. Gives results of tests and points out advantages of two-stroke cycle.

Merchant-Ship. Krupp's New Merchant-Ship Diesel-Engine, Otto Alt. Motorship, vol. 7, no. 11, Feb. 1922, pp. 99–103, 10 figs. Describes the Germaniawerft 2,000-i.hp. four-cycle-type marine oil engine. Acceptance tests.

DISTILLATION

Still Heating with Superheated Steam. Should Melting Kettles and Distillation Stills be Heated with Superheated Steam? (Sollen Schmelzkessel und Destillierblasen mit überhitztem Dampf geheizt werden?), H. Voss. Chemiker-Zeitung, vol. 46, no. 2, Jan. 5, 1922, pp. 17–18. Author explains why, in the manufacture of ceresin and distillation of sebacic acid, glycerine and mineral oil, he cannot recommend superheated steam for heating of still.

DRAWINGS

Dimensioning Dovetails. The Dimensioning of Dovetails on Drawings, H. M. Funnell. Am. Mach., vol. 56, no. 6, Feb. 9, 1922, pp. 221–222, 2 figs. System of giving all necessary figures and enabling checking. Two separate sketches made of each dovetail. Proper tolerances for each dimension.

DRILLING MACHINES

Heavy-Duty. Economy of Heavy-duty Drilling. Machinery (Lond.), vol. 19, no. 486, Jan. 19, 1922, pp. 472–477, 15 figs. Deals with the use of Colburn heavy-duty drilling machine for work where heavy cuts are required.

Jigs. Dividing Drill Jigs, Hubert Bentley. Eng. & Indus. Management, vol. 7, no. 1, Jan. 5, 1922, pp. 6–7, 4 figs. Engagement or disengagement of feed mechanism actuated by friction disks.

Multiple-Spindle. Some Special Machines for Intensive Production. Eng. Production, vol. 4, no. 68, Jan. 19, 1922, pp. 52–56, 7 figs. Describes different types of multi-spindle drilling machines developed by Defiance Machine Works, Defiance, Ohio.

Radial. Recent Machine Tool Developments, Joseph Horner. Engineering, vol. 113, no. 2927, Feb. 3, 1922, pp. 126–128, 43 figs. Describes 3-ft. 6-in. radial drilling machine constructed by James Archdale & Co., Ltd., Birmingham, England.

6-Ft. High-Speed Radial Drill. Engineering, vol. 113, no. 2923, Jan. 6, 1922, pp. 8–9, 9 figs. Describes machines manufactured by George Swift & Sons, Ltd., Halifax, running from 4 ft. 6 in. to 8-ft. radius.

DRILLS

Twist, High-Speed. Making the Latrobe High-Speed Twist Drill, S. Ashton Hand. Am. Mach., vol. 56, no. 7, Feb. 16, 1922, pp. 246–248, 9 figs. Steel rolled to obtain greatest density at points of wear. Flutes milled after twisting. Drills and shanks assembled by unusual methods.

DROP FORGING

Die Blocks. Die Blocks as Seen by the Drop Forge Plant, A. A. Blue. Forging & Heat Treating, vol. 8, no. 1, Jan. 1922, pp. 34–36. Qualities desired in a die block by various members of a drop-forge organization. Brief review of present practice and summary of established methods.

Die Blocks for Drop Forge Plant. Ry. Jl., vol. 28, no. 2, Feb. 1922, pp. 15–16. Desirable qualities of a die block. Brief review of present practice.

Fiber Stresses in Die Blocks, Leslie Aitchison. Forging & Heat Treating, vol. 8, no. 1, Jan. 1922, pp. 36–38, 2 figs. Emphasizes the appreciation that is given in England to the direction of the grain in die block with relation to maximum work to be done by the impression. Excerpt from address delivered before Assn. Drop Forgers & Stampers.

Stamps. Friction Lifters for Drop Stamps, W. H. Snow. Engineer, vol. 133, nos. 3446 and 3447, Jan. 13 and 20, 1922, pp. 34–36 and 60–62, 13 figs. Describes modified kick stamps, board drop stamps, and clutch-operated lifters.

Variables in. Variables in Drop Forge Practice, J. H. Nelson. Automotive Industries, vol. 46, no. 6, Feb. 9, 1922, pp. 274–276. Results of experiments in heat treatment of finished forgings; outlines five definite conclusions arrived at. Author states that there are seven possibilities of difference between drop forgings that are apparently identical.

E

ELASTICITY

Theory. Recent Progress in Theory of Elasticity (Neuere Fortschritte der technischen Elastizitätstheorie), L. Föppl. Zeit. für angewandte Mathematik u. Mechanik, vol. 1, no. 6, Dec. 1921, pp. 466–481. Review of literature of past decade on calculation of plates and cylindrical and spherical shells.

ELECTRIC DRIVE

Wire Mills. Electric Drives For Wire Mills. Blast Furnace & Steel Plant, vol. 10, no. 1, Jan. 1922, pp. 64–67, 7 figs. General description of modern electric drives recently installed in Alabama City works of Gulf States Steel Co.

ELECTRIC FURNACES

Counterflow-Car-Type. Counterflow Car Type Electric Furnace, Horace Drever. Forging & Heat Treating, vol. 8, no. 1, Jan. 1922, pp. 47–49, 5 figs. Describes in detail a furnace annealing gray cast iron, using the recuperative principle. Will anneal 20 tons of stock per 24-hr. day at 1450 deg. Fahr.; high thermal efficiency.

Heroult Steel. New 7-Ton Heroult Furnace. Iron Age, vol. 109, no. 5, Feb. 2, 1922, p. 325, 1 fig. Details of design capable of employing mechanical instead of hand charging.

Steel. The Present Status of Electric Furnaces in Steel Making, Harry Etchells. West of Scotland Iron & Steel Inst. Jl., vol. 29, Part 2, Nov., Session 1921–1922, pp. 2–7 and (discussion) 7–11, 1 fig. on supp. plate. Discusses various types of electric furnaces, especially the arc, and advantages of electric steel.

ELECTRIC LOCOMOTIVES

Lentz Hydraulic Drive. The Lentz Hydraulic Drive in Electric Locomotives (Das Flüssigkeitsgetriebe von Lentz in der elektrischen Lokomotive), H. Wittfeld. Elektrische Kraftbetriebe u. Bahnen, vol. 20, no. 1, Jan. 10, 1922, pp. 1–2. It is shown that possibility exists of improving electric locomotives with simple alternating current by installing a Lentz hydraulic driving gear between driver and driving axle, and that existing driver could be replaced by a synchronous driver.

Steam vs. Railway Electrification, Vincent Raven. Ry. Gaz., vol. 36, no. 1, Jan. 6, 1922, pp. 11–14, 3 figs. Some advantages which may result from substitution of electric for steam locomotive operation. Describes design of various classes of electric locomotives. Abstract of paper read before North-East Coast Instn. Engrs. & Shipbuilders. See also Engineering, vol. 113, nos. 2923 and 2924, Jan. 6 and 13, 1922, pp. 25–26 and 39–43, 13 figs. partly on supp. plate and on p. 48, and Electrician, vol. 88, no. 2277, Jan. 6, 1922, pp. 10–11, 1 fig.

Storage-Battery. Accumulator Locomotives for Steel Works. Iron & Coal Trades Rev., vol. 104, no. 2811, Jan. 13, 1922, pp. 43–44, 3 figs. Describes electric apparatus built by Sanderson Bibby Co.

ELECTRIC RAILWAYS

Insurance for. Insurance for Electric Railways. Elec. Ry. Jl., vol. 59, no. 2, Jan. 14, 1922, pp. 73–78. Discusses types of insurance applicable to railway organizations; an efficient aid in handling labor; affords opportunity for operating economies; suggestions for executive action.

ELECTRIC WELDING, ARC

Car-Wheel Flanges. Three Years Experience in Welding Worn Flanges, E. B. Gunn. Elec. Ry. Jl., vol. 59, no. 5, Feb. 4, 1922, p. 196. Satisfactory results have been obtained; wheel mileage has been increased greatly at small cost and with no bad results from a safety standpoint. Paper read before Central Elec. Ry. Assn.

Cast Iron. Arc-welding of Cast Iron, A. R. Allard. Machy. (N. Y.), vol. 28, no. 6, Feb. 1922, pp. 461–464, 6 figs. Use and application of methods for welding of cast iron by electric arc.

Increasing Welding Speed. Increasing Welding Speed, H. R. Pennington. Welding Engr., vol. 7, no. 1, Jan. 1922, pp. 24–25. Speed of electric arc welding can be increased by increasing electrode diameter and coating electrodes. Paper read before Am. Welding Soc.

Steel Structures. Electric Arc Welding in Steel Structures, James Caldwell. Engineering, vol. 113, no. 2925, Jan. 20, 1922, pp. 88–90, 4 figs. Gives examples of work done, and summary of test results to date, giving some idea of extent to which welds in steel structures can be relied upon. (Abstract.) Paper read before British Instn. Mech. Engrs.

ELEVATORS

Evolution of. Evolution of Mechanical Handling Devices of the Continuous Type. Eng. World, vol. 20, no. 2, Feb. 1922, pp. 90–91, 11 figs. Described in illustrations dating from 1560 B. C.

Power Application to. Electric Power Application to Passenger and Freight Elevators, Harrison P.

Reed. Am. Inst. Elec. Engrs Jl., vol. 41, nos. 1 and 2, Jan and Feb. 1922, pp 57–67 and 152–164, 23 figs. Notes on history and service requirements; types of elevator machines and limitation of each; characteristics and limitations of d.c. and a.c. motors, elevator controllers; brakes and other safety accessories, power consumption. Paper prepared under auspices of Subcommittee on Elevators of Indus. & Domestic Power Committee.

EMPLOYEES, TRAINING OF

Foundry Workers. Industrial Training for Foundry Workers, Thos Vickers. Foundry Trade Jl., vol. 25, nos 283 and 284, Jan. 19 and 26, 1922, pp. 42–44 and 63–65, Jan. 19. Gives historical review. Discusses the Worshipful Company of Founders; improvements necessary in modern foundry conditions; effort of Cast Iron Research Assn. to modernize foundry production; etc. Jan. 26: American system and a German scheme.

EMPLOYMENT MANAGEMENT

Analyses of Working Force. How to Analyze the Working Force, Eugene J. Benge. Management Eng., vol. 2, no. 2, Feb. 1922, pp. 79–84, 8 figs. Notes on securing facts to establish labor policies and proper working conditions.

ENGINEERING SCHOOLS

Newark Technical School. College of Engineering of the Newark Technical School. Chem. Age (N. Y.), vol. 30, no. 1, Jan. 1922, pp. 11–14, 3 figs. Discusses origin and administration of college, coöperation with industry, chemical-engineering instruction, etc.

ENGINEERS

Coöperation of Chemists and. The Coöperation of the Engineer and Chemist in the Control of Plants and Processes, G. M. Gill. Gas Jl., vol. 157, no. 3061, Jan. 11, 1922, pp. 82–86 and (discussion) 86–89, 8 figs. Deals with coal and refractory materials and outlines system which has been applied with object of standardizing quality of gas. Paper read at joint meeting of (British) Instn. Mech Engrs. and Soc. Chem. Industry. See also Engineering, vol. 113, no. 2924, Jan. 13, 1922, pp. 57–59, 8 figs.

EVAPORATORS

Liquor Concentration. The Concentration of Liquors by Evaporation, James Holmes. Chem. Trade Jl. & Chem. Engr., vol. 70, no. 1807, Jan. 6, 1922, pp. 1–3. Notes on heat losses in evaporation; typical quadruple-effect performances; improvements in design of evaporators.

EXHAUST STEAM

Utilization. The Utilization of Exhaust Steam. Engineer, vol. 133, no. 3448, Jan. 27, 1922, pp. 109–110. Outline of two papers read before joint meeting of Instn. Elec. Engrs. and Instn. Heating & Ventilating Engrs., namely, Utilisation of Exhaust Steam from Electric Generating Stations and Coal Economy, by Ingham Haden; and Utilisation of Waste Heat from Electric Generating Stations, by F._N. Whysall.

F

FACTORY MANAGEMENT

See INDUSTRIAL MANAGEMENT.

FANS

Low-Pressure. Low-Pressure Fans (Niederdruck-Ventilatoren), H. Hüttig. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 52, Dec. 24, 1921, pp. 1342–1344, 4 figs. Discusses different types, uses, and problems of drive.

Measuring Delivery. Standardized Method of Measuring Fan Delivery, E. N. Fales. Am. Soc. Heat. & Vent. Engrs. Jl., vol. 28, no. 1, Jan. 1922, pp. 1–10, 7 figs. Discusses the method as applicable not only to cooling fans, but also to larger-type propeller fans where flow is not enclosed.

FERROSILICON

Additions to Pig Iron. Ferrosilicon for the Improvement of Cast Iron (Ferro-Silizium). Zeit. für die gesamte Giessereipraxis, vol. 42, no. 53, Dec. 31, 1921, pp. 697–698. Writer gives results of his practical experiences with additions of silicon to charge, and points out that Fe Si in the form of E. K. packages is a very good medium for drawing of pig iron, and can be of great value when combined with other media.

FIRE PROTECTION

Rural Districts. Water Supply to Rural Districts for Fire-Extinguishing Purposes (Löschwasserbeschäffung in ländlichen Ortschaften), Bernard Peill. Feuerwehrtechnische Zeit., vol. 9, no. 11, Nov. 20, 1921, pp. 171–173, 2 figs. Discusses use of fire-brigade trucks with water tanks, water-scooping machines for supply of conduit or pipe systems, etc.

FLIGHT

Soaring. The Problem of Soaring Flight, A. P. Herff Aviation, vol. 12, no. 6, Feb. 6, 1922, p. 167, 3 figs. New theory based on observations of the turkey buzzard; requirements for reproducing soaring flight with airplanes.

FLOW OF FLUIDS

Commercial Pipe Lines. The Flow of Fluids through Commercial Pipe Lines, Robert E. Wilson, W. H. McAdams and M. Seltzer. Jl. Indus. & Eng. Chem., vol 14, no 2, Feb. 1922, pp. 105–119, 18 figs. Describes experimental work to fill in gaps in existing data on flow of fluids in pipes of commercial size and roughness, especially for very viscous liquids and in critical region between viscous and turbulent flow; and to determine correction factors for pressure drop around bends.

Turbulence. Experimental Investigations of Problem of Turbulence (Experimentelle Untersuchung zum Turbulenzproblem), L. Schiller. Zeit. für angewandte Mathematik u. Mechanik, vol. 1, no. 6, Dec. 1921, pp. 436–444, 7 figs. Study of conditions of stability of laminary and turbulent flow in smooth pipes.

The Origin of Turbulence (Bemerkungen über die Entstehung der Turbulenz), L. Prandtl. Zeit. für angewandte Mathematik u. Mechanik, vol. 1, no. 6, Dec. 1921, pp. 431–436, 3 figs. Results of investigations carried out by author on an open conduit, 6.5 m. long, with rectangular cross-section.

FLOW OF LIQUIDS

Viscous. The Flow of Viscous Liquids Through Slightly Conical Tubes, A. S. Hemmy. Physical Soc. of Lond. Proc., vol. 34, Part 1, Dec. 15, 1921, pp. 22–25 and (discussion) 25–26. Formula is obtained by neglecting terms containing the square of the obliquity.

FLOW OF WATER

Channels. The Discharge of Water in Raft Canals and Similar Channels (Der Wasserabfluss in Flossgassen u. ähnlichen Gerinnen), Ludwig Freytag. Forschungsarbeiten, no. 235, 1921, 85 pp., 15 figs. Contribution to theory of non-uniform movement of water.

The Movement of Water in Artificial and Natural Channels (Ueber die Bewegung des Wassers in künstlichen und naturlichen Gerinnen), Josef Putzinger. Zeit. des Oesterr. Ingenieur-u. Architekten-Vereines, vol. 74, no. 1–2, Jan. 6, 1922, pp. 4–8, 3 figs. Rules for flow of water in pipes, open channels and natural river beds, are developed which, it is believed, should be helpful in solving problem of distribution of velocity in flowing water.

Kutter's Formula. Kutter's Formula Simplified, H. E. Babbitt. Eng. & Contracting, vol. 57, no. 6, Feb. 8, 1922, p. 128. It is shown that apparent discrepancies introduced by use of modified form of formula for solution of problems ordinarily met are less than discrepancies introduced by difference of 0.001 in determination of value of n.

Pipes. Flow of Water through Spiral Riveted Steel Pipe, F. W. Greve and R. R. Martin. Purdue University Publications of Eng. Depts., vol. 5, no. 2, July 1921, 32 pp., 11 figs. Data and results of investigation upon flow of water through 4, 6, 8 and 10-in. galvanized spiral riveted steel pipes, in which effort was made to determine (1) variation of friction loss with velocity, for flow both with and against laps; (2) variation in accuracy of four types of piezometer rings; (3) comparison of friction loss with that in cast iron pipes for like conditions of diameter and velocity.

Prandtl Limit-Stream Theory. Problems of Flow and Transmission of Heat (Strömungs- und Wärmeübergangsprobleme), Max Jacob. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 53, Dec. 31, 1921, pp. 1374–1375, 1 fig. Refers to a number of articles published in Zeit. für angewandte Mathematik u. Mechanik (no. 4, 1921), most of which are based on so-called limit-layer theory of Prandtl, which is here discussed without mathematics in a manner intelligible to pratical engineers.

FLUIDS

Viscous, Motion of. The Two-dimensional Slow Motion of Vicous Fluids, L. Bairstow, B. M. Cave and E. D. Lang. Roy. Soc. Proc., vol. 100, no. A 705, Jan. 2, 1922, pp. 394–413, 7 figs. Discusses problems which require a solution of differential equation $\delta \psi = 0$.

FORGE PLANTS

Steam and Board Hammers. Comparison of Steam and Board Hammers, R. C. Jennings. Forging & Heat Treating, vol. 8, no. 1, Jan. 1922, pp. 28–29. Advocates board hammer for forging of light and medium heavy parts and steam hammer where considerable drawing or heavy forging is to be done.

Upset Forging. New Upset Forging Plant in Chicago, William E. Crocombe. Forging & Heat Treating, vol. 8, no. 1, Jan. 1922, pp. 20–22, 5 figs. Describes plant of Amforge Company, touching briefly on forge shop, die-sinking department, and inspection department.

Plant Makes Upset Forgings Exclusively. Iron Age, vol. 109, no. 6, Feb. 9, 1922, pp 401–404, 5 figs. New shop of Amforge Co. is said to be unique because of its equipment, layout and methods of stores keeping, ventilating system, etc.

FORGES

Gas Forges. Use of Gas Forges in Repair Shops, J. L. Springer. Gas Age-Rec., vol. 49, no. 5, Feb 4, 1922, pp. 133–134. Deals with temperature regulation, combustion gases, sulphur in burning gases, and bench forges.

FOUNDRIES

Gray-Iron. Complete Huge Wisconsin Foundry. Foundry, vol. 50, no. 3, Feb. 1, 1922, pp. 89–98, 15 figs. Describes new plant of Fairbanks, Morse & Co., with capacity of 500 tons per day of gray-iron castings varying in weight from 1 lb. to 15 tons.

FUELS

Bagasse, Calorific Value of. The Calorific Value of Bagasse, P. H. Parr. Int. Sugar Jl., vol. 24, no. 277, Jan. 1922, pp. 13–18. Determines heating value for bagasse, its composition, etc. Gives some comparative figures for wood.

Economy. A Session on Fuel Economy. Mech. Eng., vol. 44, no. 2, Feb. 1922, pp. 112–113 and 118. Discussion of four papers at A.S.M.E. meeting, namely, Boiler Plant Efficiency, by Victor J. Azbe; Boiler and Furnace Economy, D. S. Jacobus; Fuel Saving in Relation to Capital Necessary, Joseph Harrington; and Fuel Saving in Modern Gas Producers and Industrial Furnaces, W. B. Chapman. Brings out many experiences in economic boiler and furnace operation, leading to great fuel savings.

Low-Grade. Recent Fuel Investigations. Power Plant Eng., vol. 26, no. 3, Feb. 1, 1922, pp. 162–164. Experiments conducted to determine feasibility of utilizing lower-grade fuels for steaming purposes.

[See also OIL FUEL; PULVERIZED COAL.]

FURNACES

Combination Welding and Preheating. Combination Welding—Preheating Furnace, F. M. Gloyd. Forging & Heat Treating, vol. 8, no. 1, Jan. 1922, pp. 84–85 and 89, 7 figs. Methods at plant of A. A. Simonds & Sons Co., Dayton, Ohio, using stoker-fired furnace for preheating and welding. Special tongs and metric clock increase production materially.

FURNACES, BOILER

Low-Grade Fuels. Step Grates, Semi-Producer-Type Furnaces, Forced Draft, and Coal Burned per Unit Grate Area (Treppenroste, Halbgasfeuerungen, Unterwind und Rostbelastung), H. Pradel. Braunkohle, vol. 20, no. 41, Jan. 14, 1922, pp. 641–648, 11 figs. Discusses efficiency of and gives results of tests with the Topf high-capacity and the Bergmann semi-producer furnaces, Pluto stoker, etc., for utilization of low-grade fuel.

FURNACES, HEATING

Forgings. Heating Furnaces For Forgings, C. Fischer. Blast Furnace & Steel Plant, vol. 10, no. 1, Jan. 1922, pp. 94–95, 3 figs. Discusses utilization of waste gases from heating furnaces, including direct preheating of steel by waste gases.

FUSION WELDING

Castings. Utilizing Fusion Welding on Castings, H. S. Rawdon. Iron Trade Rev., vol. 70, no. 4, Jan. 26, 1922, pp. 274–276. Includes table summarizing mechanical properties of low-carbon cast steel prepared by thermit process, and by arc-fusion. Discussion of paper entitled Fusion Welding, by S. W. Miller, presented at Am. Iron & Steel Inst.

G

GAGES

Adjustable Limit. The Wickman Adjustable Limit Gauge for Taps. Engineering, vol. 113, no. 2926, Jan. 27, 1922, op. 100–102, 13 figs. Describes adjustable thread caliper gage which enables screws and externally threaded part to be controlled within any desired limits of accuracy in pitch, effective diameter, etc. Its use for tap inspection.

Error of Contact. Tests to Determine Error of Contact (Versuche zur Bestimmung des Berührungfehlers), Eugen Simon. Werkstattstechnik, vol. 16, no. 1, Jan. 1, 1922, pp. 6–8. Results of tests conducted by sub-committee on gage allowances of German Industries Committee on Standards (NDI), to determine error occurring in measurement of same hole with different gages brought about by giving to all gages the same diameter without regard to influence of varying sizes of their measuring surfaces.

Multiple-Spline, Grinding. Grinding Multiple Spline Gauges. Machinery (Lond.), vol. 19, no. 485, Jan. 12, 1922, pp. 449–450, 3 figs. Describes method of grinding multiple-spline gages having six or more splines, which has proved successful in practice.

Snap, Setting Machine for. Snap Gauge Setting Machine. Machinery (Lond.), vol. 19, no. 485, Jan. 12, 1922, pp. 439–440, 3 figs. Range of machine covers settings from 1/2 up to 10 in., and the sensitiveness is to 0.0001-in.

GAS

Straw. Gas Made by Carbonizing Straw, Harry E. Roethe. Gas Age-Rec., vol. 49, no. 3, Jan. 21, 1922, pp. 75–76, 2 figs. Discusses destructive distillation of straw and similar material, and the gas producing plant on the government farms at Arlington, Va., for experimental work.

GAS ANALYSIS

Stack and Fuel. Graphical Treatment of Stack Gas Analysis and Fuel Gas Analysis, W. Trinks. Blast Furnace & Steel Plant, vol. 10, no. 1, Jan. 1922, pp. 50–58, 5 figs. Gives most important phases of work regarding charts introduced by Wa. Ostwald and laid out in book called "Beiträge zur graphischen Feurungstechnik," on calculation for stack gas analysis for producer gas, natural gas, by-product tar, coke-oven gas, and for coal.

GAS PRODUCERS

German Bamag. Improvements and Operating Experiences with Gas-Producer Plants for Large Variety of Fuels (Neuerungen und Betriebsergebnisse von Gasgeneratoranlagen für die verschiedensten Brennstoffarten), H. Lichte. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, nos. 48 and 49, Dec. 2 and 9, 1921, pp. 385–387 and 390–399, 15 figs. Describes Bamag producers in the following constructions: revolving-grate producer with and without water-cooling jacket; high-pressure revolving-grate producer; and grateless producer.

Hot-Blast Application. Using Hot Air in Gas Producers for Fusing Ash (L'Emploi du vent chaud dans les gazogènes à fusion des cendres), A. Dessemond. Le Genie Civil, vol. 79, no. 26, Dec. 24, 1921, pp. 561-564, 1 fig. Describes installation of Société des Houillères de St. Etienne, showing success of system with fuel containing up to 60 per cent ash, as well as with heterogeneous fuels.

GASES

Cleaning. A New Process of Cleaning Gases and Vapors (Ein neues Verfahren zur Reinigung von Gasen und Dämpfen), E. Stach. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 49, Dec. 3, 1921, pp. 1265-1267, 7 figs. Points out that for removal from gases and vapors of dust, tar, oil, etc., according to the Freytag-Metzler rotary-filter process, a much greater degree of cleanliness is achieved than with methods heretofore in use. Writer recommends further development of process for removal of oil from vapor and air filtration.

Rotary-Type Gas Filter. Mech. Eng., vol. 44, no. 2, Feb. 1922, p. 126, 1 fig. Describes process intended to be used for removing dust, tar, oil and similar impurities from gases and vapors, developed by Freytag-Metzler and tested by E. Stach and Dr. Alexi. Translated from Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 49, Dec. 3, 1921, pp. 1265-1267, 7 figs.

Compressed, Steel Containers for. Explosions of Steel Flasks (Stahlflaschen-Explosionen). Zeit. fur komprimierte u. flüssige Gase, vol. 21, nos. 9 and 11, 1920-21, pp. 104-105 and 128-129. Account of series of serious accidents which have occurred in the last years in the handling of compressed and liquid gases, and results of investigations.

Oxy-Hydrogen, Ignition Point of. Investigations of the Ignition Point of Oxy-Hydrogen Gas (Untersuchungen über den Entzündungpunkt des Knallgases), Alexander Mitscherlich. Zeit. für komprimierte u. flüssige Gase, vol. 21, nos. 8, 9 and 10, 1920-21, pp. 89-93, 101-103 and 125-128, 6 figs. Account and results of tests and description of testing apparatus. Article was published during war in Zeit. für anorganische Chemie, vol. 98, from which above is reprinted.

GEAR CUTTING

Fixing and Releasing of Blanks. Rapid Holding and Releasing of Gear Blanks, Fred Horner. Can. Machy., vol. 27, no. 5, Feb. 2, 1922, pp. 40-41 and 46, 10 figs. Holding with spring collets of external or internal type; use of draw-back rod; etc.

Worm-Gear Machine. A New Worm Gear Generating Machine. Engineer, vol. 133, no. 3447, Jan. 20, 1922, pp. 78-79, 9 figs. New machine by Smith & Coventry, Ltd., Manchester, England, of tangent feed pattern, more particularly adapted to generation of single wheels or wheels in small numbers by means of less expensive fly cutter.

GEARS

Automobile, Machining. Cost-reducing Tooling Equipments, Ralph E. Flanders. Machinery (Lond.), vol. 19, no. 485, Jan. 12, 1922, pp. 441-444, 10 figs. Machines and tooling equipments used for performing turning, boring, facing, and recessing operations on automobile gears.

Tooling Equipment for Automobile Gears and Ball Races, Ralph E. Flanders. Machy. (N. Y.), vol. 28, no. 6, Feb. 1922, pp. 447-451, 14 figs. Describes jobs performed on Fay automatic lathes and operations on double-spindle flat turret lathes and Hartness automatic lathes.

Grinding Hardened Teeth. Grinding Hardened Gear Teeth. Eng. Production, vol. 4, no. 67, Jan. 12, 1922, pp. 42-44, 6 figs. Describes machine for finish grinding spur gear teeth to within definite limits of accuracy, and without producing scrap.

High-Carbon, Reclaiming. Reclaiming High Carbon Gears, R. L. Dowdell. Am. Soc. for Steel Treating Trans., vol. 2, no. 4, Jan. 1922, pp. 320-322, 8 figs. Describes method by which these gears could be reclaimed by heat treatment which would give them a tough core with a hard case by varying the internal structures without altering carbon content.

Involute. Gear Tooth Shapes, E. W. Miller. Am. Mach., vol. 56, nos. 4 and 5, Jan. 26 and Feb. 2, 1922, pp. 129-132 and 168-172, 26 figs. Study of fundamentals in principles of involute gearing in endeavor to find a suitable standard form and pressure angle.

The Evolution of the Involute Gear Tooth—XI, A. Fisher. Machy. (Lond.), vol. 19, no. 487, Jan. 26, 1922, pp. 513-517, 6 figs. Involute pitch and pressure-angle permutability.

Spur, Inspection of. Inspection of Spur Gears, D. Vaughn Waters. Machy. (N. Y.), vol. 28, no. 6, Feb. 1922, pp. 465-466, 4 figs. Describes practice of Gould & Eberhardt, Newark, N. J., in inspecting spur gears, with particular reference to uniformity of tooth spacing and concentricity of pitch circle relative to axis of gear.

Transmission. Transmission (Les Transmissions), Legrand-Ribet. L'Outillage, vol. 241, no. 1, Jan. 7, 1922, pp. 8-17, 44 figs. Discusses dimensions, speed of transmissions, bearings, brakes, pulleys, etc.

Variable-Speed. Gears and Mechanisms at Variable Speed (Les embrayages et les mécanismes en mouvement varié), H. Meuris. Annales des Travaux Publics de Belgique, vol. 22, Dec. 1921, pp. 993-1006, 4 figs. Distinguishes between those where starting and stopping occurs rarely, and where it occurs frequently, and studies useful work and lost work mathematically.

GRINDING MACHINES

Practice. Grinding Machines and Practice—II-VII. Mech. World, vols. 70 and 71, nos. 1812, 1816, 1819, 1821, 1824 and 1829, Sept. 23, Oct. 21, Nov. 11, 25, Dec. 16, 1921 and Jan. 20, 1922, pp. 238-239, 318-320, 378-379, 418-419, p. 478 and pp. 42-43, 32 figs. Sept. 23: Discusses grain and grade, bonds used for vitrified silicate, elastic and other wheels, and natural and artificial abrasives. Oct. 21: Selection of wheels for a given job; hardness, speeds, dressing and truing wheels, etc. Nov. 11 and 25: Design of wheel mountings. Dec. 16: Discusses the question of protection hoods and the production of sparks. Jan. 20: Cylindrical grinding machines, and wheel-spindle mounting for plain grinding machines. (To be continued.)

Wheel-Truing Attachment for Thread. Wheel-Truing Attachment for Screw-Thread Grinding. Engineering, vol. 113, no. 2925, Jan. 20, 1922, p. 76, 4 figs. on p. 78. Describes new attachment brought out by Precision & Thread Grinder Mfg. Co., Philadelphia, Pa., primarily intended for use with maker's multi-graduated precision thread grinder.

H

HARDNESS

Testing. Ball Hardness Testing of Semi-Steel (L'Essai de Dureté à la bille sur la Fonte aciérée), M. Portevin. Fonderie Moderne, no. 11, Nov. 1921, pp. 318-321, 2 figs. Establishes empiric formulas and gives advantages of Brinell test.

Hardness Testing (Beitrag zur Härteprüfung), F. Waizenegger. Forschungsarbeiten, no. 238, 1921, 32 pp., 13 figs. Notes on the Brinell test; effect of load, ball diameter and duration of load on coefficient hardness; calculation of maximum coefficient of hardness; comparison of different materials by means of maximum hardness coefficient. Tests of A. Kürth to determine relation between maximum hardness coefficient and (a) tensile strength, (b) yield point and (c) temperature.

Some Brinell Hardness Measurements on Small Specimens, E. D. Campbell. Am. Soc. for Steel Treating Trans., vol. 2, no. 4, Jan. 1922, pp. 269-273, 1 fig. Describes attachment for the standard Alpha Brinell machine which enables hardness measurments to be made on small bars with almost as much ease and accuracy as can be done on larger specimens.

HEAT TREATING

Electric. Economics of Electric Heat Treating, E. F. Collins. Forging & Heat Treating, vol. 8, no. 1, Jan. 1922, pp. 76-81, 5 figs. Method of electric heat transmission and delivery to charge; importance of insulation in various types of furnaces.

HEAT TRANSMISSION

Liquid to Liquid. Numerical Law of Heat Transmission Between Liquids in Industrial Heat Exchangers (Lois numériques de la Transmission de la Chaleur entre les fluides dans les Echangeurs Industriels), H. Dieterlen. Chaleur et Industrie, vol. 2, nos. 17, 18 and 19, Sept., Oct. and Nov. 1921, pp. 570-579, 649-652 and 736-746, 16 figs. Sept.: The coefficient of transmission through walls. Oct.: Formulas used. Nov.: Construction of economisers of the Kablitz type.

HEATING

Direct-Indirect. The Weak Spots in Direct-Indirect Heating, E. Vernon Hill. Heat. & Vent. Mag., vol. 19, no. 1, Jan. 1922, pp. 29-32, 5 figs. Results of test of air conditions in Greentown (Ind.) High School, made at request of Ind. State Board of Health, which has not approved use of direct-indirect heating systems.

HEATING, ELECTRIC

Residences. Electric Heating of Residences, Edgar Allan Loew. University Wash. Eng. Experiment Station Bul., no. 15, Dec. 1921, 44 pp., 8 figs. Experiments and reports on electric house heating. Experiences with domestic heating in Tacoma, Wash., and conclusions reached. Comparison of heating electrically and by means of coal; and possibilities in use of surplus, off-peak and seasonal power.

Thermal Processes. Electric Heat for Thermal Processes, E. F. Collins. Jl. Indus. & Eng. Chem., vol. 14, no. 2, Feb. 1922, pp. 101-104, 6 figs. Discusses heat generation and heat transmission, and gives examples of the various installations applying electric heat industrially.

HEATING, FACTORY

Analysis. An Analysis of Factory Heating, M. C. W. Tomilson. Factory, vol. 28, no. 2, Feb. 1922, pp. 162-164, 4 figs. Twelve ways to get more heat from less coal.

HELICOPTERS

Design. Theoretical Discussion of the Problem of Helicopters (Theoretische Bemerkungen zur Frage des Schraubenfliegers), Th. v. Kàrmàn. Zeit. fur Flutechnik u. Motorluftschiffahrt, vol. 12, no. 24, Dec. 31, 1921, pp. 345-354, 8 figs. Discusses the three theoretical problems governing design of helicopters. It is believed that difficulties encountered in construction of a serviceable helicopter are greater than is generally supposed, though not insurmountable. Modern types of helicopters are described by same author in same journal (pp. 360-361, 4 figs.)

HOISTS

Electric. Factors Affecting Installation of Electric Motors for Hoisting, Gordon Fox. Elec. World, vol. 79, no. 4, Jan. 28, 1922, pp. 171-173, 1 fig. Methods of determining size of motors required. Various types of skip hoists and their use. Advantages and disadvantages of a.c. and d.c. drives for skip hoists.

HYDROELECTRIC DEVELOPMENTS

Upper Rhone, France. Improvements in the Upper Rhone (L'Amenagement du Haut Rhône), Leon Perrier. Annales de l'Energie, vol. 1, no. 2, Mar.-Apr. 1921, pp. 49-57, 1 fig. Technical data and principal projects for making use of water power and navigating the French Upper Rhone.

Western U. S. Projects. Some Western Hydroelectric Projects Under Way in 1921 or Definitely Scheduled for 1922. Jl. Electricity & Western Industry, vol. 48, no. 2, Jan. 15, 1922, pp. 60-61. List giving essential data in tabular form.

HYDROELECTRIC PLANTS

Barcelona, Spain. Power Transmission by the Catalan Gas and Electric Co. (La transmission d'énergie Seira-Barcelone de la Societé catalane du Gaz et l'Électricité à Barcelone), J. Reyval. Revue Genérale de l'Électricite, vol. 11, no. 1, Jan. 7, 1922, pp. 11-31, 31 figs. Describes control of water power, the hydroelectric plant and its equipment at Seira, transmission lines, substations, transformers, etc.

Bathurst, N. B. Hydro-Electric Developments Near Bathurst, N. B., James Dick. Can. Engr., vol. 42, no. 5, Jan. 31, 1922, pp. 181-185, 10 figs. Construction details of plant at Grand Falls, Nepisiguit River. 15 mi. of standard-gage railway laid to work. Power house and dam of reinforced concrete. Transmission line is 19 mi. long.

Design. Hydro-Electric Developments, W. M. White. Denki Gakkwai Zasshi (Jl. Inst. Elec. Engrs. Japan), no. 402, Jan. 1922, pp. 21-31, 6 figs. Deals with design of power house and dam, tunnels, canals, pipe lines, turbines, draft tubes and tail race.

Increasing Capacity. Increasing Capacity of Parnahyba Plant, H. P. Quick. Power, vol. 55, no. 5, Feb. 7, 1922, pp. 212-213, 3 figs. Describes how a hydroelectric plant in Brazil, originally laid out for 16,000 hp. was modified to develop double this capacity.

Pit River, California. The Pit River Hydroelectric Power Project, Charles W. Geiger. Power Plant Eng., vol. 26, no. 2, Jan. 15, 1922, pp. 105-111, 8 figs. Describes first two plants of Pacific Gas & Elec. Co. on its Pit River system in Shasta county where unusual geological formation makes possible operation of a system without necessity of artificial storage capacity.

Queenston-Chippawa. First Unit for Queenston-Chippawa Water Power Plant Opened. Eng. News-Rec., vol. 88, no. 3, Jan. 19, 1922, pp. 110-111. Includes views of completed hydroelectric development around Niagara Falls in Ontario.

South Africa. Description of the Hydroelectric Power Plant Installed at Howick Falls, H. W. Miller. So. African Instn. of Engrs. Jl., vol. 20, no. 4, Nov. 1921, pp. 62-71, 6 figs. Describes work connected with construction of concrete diversion weir, a pipe line of some 600 ft. in length with upper section 34 in. diameter by 200 ft. long, the power house and machinery, etc. See also So. African Eng., vol. 32, no. 12, Dec. 31, 1921, pp. 242-243.

Trash-Rack Rake. Mechanical Trash-Rack Rake, I. W. Jones. Power, vol. 55, no. 4, Jan. 24, 1922, pp. 131-132, 3 figs. Describes rack rake developed by author, consisting of motor-operated car mounted on wheels designed to travel on rails inlaid in rack platform. Rake is supported by light structural-steel framework and operated by four steel cables.

Wales. Hydro-Electric Installation at Denbigh Asylum. Engineer, vol. 133, no. 3446, Jan. 13, 1922, p. 50, 8 figs. Describes erection of dam 160 ft. long to give fall of 15 ft., a fish pass, and generating station in which are installed a water turbine, electric generator and switchgear.

HYDRAULIC TURBINES

Governors. Hydraulic Turbine Governors, W. R. Kepler. Elec. Jl., vol. 19, no. 2, Feb. 1922, pp. 60-68, 12 figs. Discusses limitation of speed to suit conditions demanded by character of load. Governing element may be grouped into three sections, (1) flyballs, valve and compensating device, (2) pressure system and (3) mechanism for applying energy of pressure system to change amount of water through turbine.

Kaplan. The Brake Horsepower Guarantees of the Kaplan Turbine Concern in the Storek Turbine Experimental Station in Brünn (Austria) (Die Garantiebremsungen des Kaplanturbinenkonzerns in der Turbinenversuchsanstalt der Firma Storek in Brünn), J. Slavik and P. Walther. Elektrotechnik u. Maschinenbau, vol. 40, no. 2, Jan. 8, 1922, pp. 13-15, 4 figs. Results of brake tests carried out under supervision of Dr. Kaplan and his assistants and members of Kaplan Turbine Concern, not only achieved, but greatly exceeded guaranteed efficiency.

I

ICE MANUFACTURE

Hoisting System. Economical Ice Harvesting, Otto Luhr. Ice & Refrigeration, vol. 62, no. 1, Jan. 1922, pp. 16-17. Describes a multiple ice-hoisting system, hoisting a whole row of cans at a time by putting cans in a framework and attaching air-agitating device onto framework so that only one air connection need be made. Paper read before Nat. Assn. Pratical Refrig. Engrs.

Refrigerating Process. Voorhees' Refrigerating Economies, Gardner T. Voorhees. Ice & Refrigeration, vol. 62, no. 1, Jan. 1922, p. 22, 2 figs. Discusses the

multiple-effect receiver, multiple-effect compressor, compressed exhaust-steam process, double-freezing can ice process, and the non-cracked ice and fore-cooler process. Paper read before Nat. Assn. Pratical Refrig. Engrs.

ILLUMINATION

Committee Reports. Illumination Items by the Lighting and Illumination Committee. Am. Inst Elec. Engrs. Jl., vol. 41, no. 2, Feb. 1922, pp. 149 151, 4 figs. Notes on preliminary report by P. W. Cobb on influence of illumination levels upon speed of vision; electric sign lighting; and report of Committee on Elimination of Waste in Industry of Am. Eng. Council on accidents due to eye defects.

IMPACT

Bars, Duration of. Duration of Impact of Bars, Erwin W. Tschudi. Physical Rev., vol. 18, no. 6, Dec. 1921, pp. 423-430, 4 figs. Experiments show that duration of impact is not a linear function of length of colliding bars, a fact directly contrary to compressional wave theory.

INDICATORS

Steam-Engine. The Steam-Engine Indicator Power, vol. 55, nos. 4, 5 and 6, Jan. 24, 31 and Feb. 7, 1922, pp. 142–144, 6 figs., 182–184, 10 figs. and 224, 3 figs. Jan. 24: What a reducing rig is and how it is made. Jan. 31: Reducing rigs on modern engines, and reducing wheels and cylinder connections. Feb. 7: Checking reducing rig for errors.

INDUSTRIAL MANAGEMENT

Job Analysis. Job Analysis as a Factor in Cost Reduction, Richard S. Uhrbrock. Indus. Management, vol. 63, no. 2, Feb. 1922, pp. 100–102. Qualifications of the analyst and methods of approach.

Overhead Distribution. Lightening the Factory Burden, Clinton W. Bennett. Indus. Management, vol. 63, no. 2, Feb. 1922, pp. 103–106, 5 figs. Distribution of overhead for analysis and control.

Production Control. Production Control by Graphics. Machinery (Lond.), vol. 19, no. 484, Jan. 5, 1922, pp. 405–412, 13 figs. Describes system employing graphic charts for controlling shop operations in plant making cotton looms and automatic attachments for looms.

Production Planning. Production Planning at the Dennison Plant. Factory, vol. 28, no. 2, Feb. 1922, pp. 159–162, 4 figs. Describes system which controls made-to-order goods almost entirely, where each order requires special attention. Its main object and accomplishment is to coördinate all departments to secure most satisfactory ultimate results.

Small Shop Overhead. Minimum Shop Operation Without Loss, D. S. Cole. Indus. Management, vol. 63, no. 2, Feb. 1922, pp. 96–97, 1 fig. Describes how small industrial plant operated plant during period of curtailed manufacturing operations, without allowing overhead or fixed expense to force losses.

[See also TIME STUDY.]

INDUSTRIAL ORGANIZATION

Drafting Rooms. The Organisation of a Jig and Tool Drawing Office, H. Varley. Eng. & Indus. Management, vol. 7, no. 5, Feb. 2, 1922, pp. 123–126, 4 figs. Development and scope of tool office; size of tool drawing office; duties of jig and tool office, relationship with productive departments; layout of office organization; and division of work.

Knitting Mills. The Organization of Knitting Mills Carle M. Bigelow. Management Eng., vol. 2, no. 2, Feb. 1922, pp. 111–116, 10 figs. Standardizing work of planning department.

INDUSTRIAL RELATIONS

Alliance of Employers and Employees. Association of Employers and Employees. Iron Age, vol. 109, no. 6, Feb. 9, 1922, p. 407. Unique institution in Cleveland in which better understanding is brought about. Educational and other features.

INJECTORS

Exhaust-Steam, Locomotive. An Improved Exhaust Injector For Locomotives. Ry. Engr., vol. 43, no. 504, Jan. 1922, pp. 9–10 and 12, 3 figs. Describes advantages of new F type injector made by Davies & Metcalfe, Romiley.

Metcalf's Exhaust Steam Injector. Engineering, vol. 113, no. 2925, Jan. 20, 1922, pp. 71–72, 4 figs. New pattern, constructed by Davies & Metcalfe, Ltd., Romiley, England, is capable of delivering water against pressure of 150 lb. per sq. in., with 1 lb. exhaust pressure, thus greatly reducing amount of live steam necessary to get up to normal working pressures in locomotive pratice.

INSTRUMENTS

Control. The Organization of Instrument Control in Industrial Plants, Frederick J. Schlink. Management Eng., vol. 2, no. 2, Feb. 1922, pp. 67 72, 4 figs. Deals with factors in instrument control and describes some typical installations Qualifications and duties of inspectors. Calibration and tagging of instruments Installation, repair and maintenance.

INTERNAL-COMBUSTION ENGINES

Lubricating Oils. Lubricating Oil, W. R. G. Atkins. Automobile Engr., vol. 11, no. 158, Dec. 1921, pp. 450 452. Factors affecting its consumption in internal-combustion engines.

Research Recent Research Work on the Internal Combustion Engine, Harry R. Ricardo Automotive Industries, vol. 46, no. 3, Jan. 19, 1922, pp. 126 133, 15 figs. Discusses effect of latent heat of vaporization, mean volatility, temperature, pressure, dilution, mixture strength, stratification and other factors upon combustion, and especially the detonation, of various fuels. Condensed from paper read before Soc. Automotive Engrs.

Semi-Ideal Gases for. Semi-Ideal Gases and Efficiency of Internal-Combustion Engines (Halbideale Gase und Wirkungsgrad der Verbrennungsmaschinen), M. Seiliger. Zeit. des Vereines deutscher Ingenieure, vol. 66, no. 1, Jan. 7, 1922, pp. 8–10, 1 fig. It is claimed that gases of internal-combustion engines are not ideal, but semi-ideal. Their adiabatics cannot be expressed by a polytropic curve. Equations of adiabatics and isodiabatics for semi-ideal gases are developed. Based on these equations and with regard to volume reduction and change of specific heat in combustion, the efficiency of a general working process is determined

[See also AIRPLANE ENGINES; AUTOMOBILE ENGINES; DIESEL ENGINES; OIL ENGINES; SEMI-DIESEL ENGINES.]

IRON

Charcoal, Manufacture of. Manufacture of Charcoal Iron and Charcoal Iron Boiler Tubes, W. H. S. Bateman. Southern & Southwestern Ry. Club, vol. 16, no. 6, Nov. 17, 1921, pp. 10–17 and (discussion) 17–21. Describes processes of manufacture and method of rolling skelp for tubes.

IRON ALLOYS

Silicon-Iron. Silico-Thermy and Its Practical Application, C. A. Heise. Iron Age, vol. 109, no. 5, Feb. 2, 1922, pp. 337–338, 5 figs. German iron-silicon castings of "thermisilid" made by thermal reactions. Silicides which are formed. Properties of new alloy. Paper read by Richard Walter before German Met. Soc.

IRON, PIG

Pig-Breaking Machine. A New Pig-Breaking Machine. Foundry Trade Jl., vol. 24, no. 280, Dec. 29, 1921, p. 519, 2 figs. Describes patent of E. Roper & Co., of Keighley, made either for belt or direct motor drive.

Synthetic. Recarburising Steel for Iron Foundry Use. Foundry Trade Jl., vol. 25, no. 282, Jan. 12, 1922, pp. 29–30. Describes series of trials made at Rombach, and gives analyses of cupola-melted steel scrap, billets and slags, also typical analyses of recarburized Bessemer steel and Bessemer steel recarburized with charcoal. From Stahl u. Eisen.

Synthetic Iron (Considérations sur les Fontes synthétiques), A. Keller. Fonderie Moderne, no. 11, Nov. 1921, pp. 327–336, 10 figs. Discusses process of making synthetic iron from scrap in the electric furnace, and its application for various purposes.

The Production of Synthetic Pig Iron By the Oehler & Cie. Iron & Steel Works, Inc., Aarau (Switzerland) [Ueber die Herstellung von synthetischem Roheisen bei den Eisen- und Stahlwerken Oehler & Cie., A.-G., Aarau (Schweiz)], K. Dornhecker. Stahl u. Eisen, vol. 41, no. 52, Dec. 29, 1921, pp. 1881–1889, 14 figs. partly on supp. plate. Notes on general aspects of production of pig iron from scrap and fundamentals of different processes; advantages of production in electric furnace with extensive carburization in the solid state. Details of the Aarau plant and planned enlargement.

L

LABORATORIES

Engineering Works. An Engineering Works Laboratory. Engineering, vol. 113, no. 2924, Jan. 13, 1922, pp. 34–36, 4 figs. Describes laboratory and equipment of W. H. Allen Sons & Co., Ltd., Bedford, England, manufacturers of high-speed engines, turbines, oil engines, electrical machinery, etc.

LATHES

Scroll-Forming. Lathe Formers, V. Gartside. Machy. (Lond.), vol. 19, no. 487, Jan. 26, 1922, pp. 505-507, 7 figs. Discusses scroll-turning lathes.

Turret. Turret Lathe Tooling. Machy. (Lond.), vol. 19, no. 487, Jan. 26, 1922, pp. 500-501, 4 figs. Equipment for machining differential gear housings on turret lathes.

Wheel. A New 48-In. Wheel Lathe Ry. Gaz., vol. 35, no. 22, Nov. 25, 1921, pp. 815-816, 2 figs. Describes a modern wheel lathe characterized by abundance of driving power, rigidity, efficient operating facilities, and high output, made by Noble & Lund, Ltd., Felling-on-Tyne.

LEATHER INDUSTRY

Research. Research in Leather Manufacture, Arthur W. Thomas. Mech. Eng., vol. 44, no. 2, Feb. 1922, p 116. Describes work which has been done and points out that there is a great field in tanning industry, by prosecution of scientific research, to eliminate unnecessary wastes due to lack of knowledge of reactions.

LIGHTHOUSES

Aerial. Aerial Lighthouses. Flight, vol. 14, no. 4, Jan. 26, 1922, pp. 52-54, 3 figs. Describes the 1,000,000,000-c.p. lighthouse which is being erected at Dijon for aerial routes between Paris and Algiers, Italy and Switzerland, made by Barbier, Bernard and Turenne, of Paris.

LIQUIDS

Emulsified, Pumping. Pumping Liquids and Light Bodies by Emulsifying (Pompage des liquides et des corps légers par émulsion), Henry Béduwé. Révue Universelle des Mines, vol. 11, nos. 1 and 2, Oct. 1 and 15, 1921, pp. 57 64 and 155 160, 7 figs. Oct. 1 Describes application and operation of air lift pump, and experiments made by Westinghouse Air Brake Co. Oct. 15: Discusses industrial applications of emulsion pump, pumping by compressed air, etc.

LOCOMOTIVE BOILERS

Pulverized-Coal-Fired. Pioneer Boilers fired With Pulverized Coal, F. P. Coffin. Combustion, vol. 6, no. 2, Feb. 1922, pp. 74–77 and 95, 2 figs. Describes the Bettington boiler, designed for firing with powdered coal or coal dust; the Erie City Iron Works boiler, designed by Aero Pulverizer Co; and the American Locomotive Works boiler. (Abstract.)

Tube Fractures. Notes on Fractures in Locomotive Boiler Tubes, Henry Fowler. Faraday Soc. Trans., vol. 17, part 1, no. 49, Dec. 1921, pp. 82–90, 11 figs. Results of investigation of large tubes of boiler on Midland Railway showing brittleness and fractures.

LOCOMOTIVES

Adhesion and Rack. Adhesion and Rack Locomotive for Sumatra, S. Abt. Ry. Age, vol. 72, no. 4, Jan. 28, 1922, pp. 263–266, 7 figs. Describes 0-10-0 type superheater four-cylinder compound locomotive of Dutch State Railways; tractive effort 30,865 lb.

British Types, 1921. Locomotives in 1921. Engineer, vol. 133, no. 3445, Jan. 6, 1922, pp. 10–12, 17 figs. partly on supp. plates and p. 14. Data on locomotives built for different British roads.

Electric. See ELECTRIC LOCOMOTIVES.

Fireless. The Explosion of a Fireless Locomotive in the German Works in Dachau (Zerknall einer feuerlosen Lokomotive in den Deutschen Werken in Dachau). Zeit des Bayerischen Revisions-Vereins, vol. 25, nos. 23 and 24, Dec. 15 and 31, 1921, pp. 191–193 and 200-204, 14 figs. Account of explosion of locomotive for operating pressure of 13 atmos., equipped with simple cylindrical, 4-meter-long steam boiler with diam. of 1690 mm. Results of investigation lead to conclusions that explosion was due to disadvantageous shape of boiler head; inferior quality of boiler plate; and to deficient heat treatment in construction of head.

Freight. Geared Locomotive for Freight Service. Ry. Jl., vol. 28, no. 2, Feb. 1922, p. 12, 1 fig. Particulars of 150-ton Shay geared three-truck type locomotive for freight service in mountainous regions. Tractive power, 59,740 lb. Built by Lima Locomotive Works, Inc., for Greenbriar, Cheat & Elk Railroad.

Gasoline. A Practical and Powerful Gasoline Switch Locomotive, L. C. Josephs, Jr. Ry. Rev., vol. 70, no. 3, Jan. 21, 1922, pp. 82–84, 4 figs. Describes the Mack gasoline locomotive by which smoke and fire risks are eliminated.

New Castle Mfg. Co. The New Castle Manufacturing Company, J. Snowden Bell. Ry. & Locomotive Eng., vol. 35, no. 1, Jan. 1922, pp. 1–4, 3 figs. Describes first locomotive built by Stephenson and locomotive "America" built by New Castle Mfg. Co.

Rebuilt. Rebuilt Locomotives, London & South Western Railway. Ry. Gaz., vol. 36, no. 1, Jan. 6, 1922, pp. 21–23, 6 figs. By rebuilding, tractive effort is raised from 21,620 to 23,500 lb. for freight engines, and from 16,900 to 20,240 lb. for tank engines.

Stokers. An Everyday Run With the New Hanna Type H-2 Stoker. Ry. Rev., vol. 70, no. 2, Jan. 14, 1922, pp. 51-53, 2 figs. Describes performance on Norfolk & Western mountain-type locomotive; tractive effort, 57,200 lb.

Three-Cylinder. Three-Cylinder Locomotive for Spanish Railways. Engineer, vol. 133, no. 3449, Feb. 3, 1922, pp. 134-136, 8 figs. partly on supp plate. Describes 8-coupled locomotive of 4-8-0 type, with double bogie tender, built by Yorkshire Engine Co., Ltd., Sheffield, England. Gives characteristics of engine and tender.

Truck Arrangement. On the Question of Bogies (Trucks), Axles and Springs of Locomotives, M. Bochet. Int. Ry. Assn. Bul., vol. 4, no. 1, Jan. 1922, pp. 193-250, 20 figs. Report No. 2 (All countries, except those using English language, Belgium and Scandinavian countries). Best arrangement of truck, axles and springs of locomotive for high speeds, with long wheelbases, so as to facilitate running round curves and to insure proper stability of engines.

LUBRICATING OILS

Treatment of Distillates. The Treatment of Refined Oil Distillate, C. D. Dean. Can. Machy., vol. 27, no. 5, Feb. 2, 1922, pp. 42–44 and 46. Removing wax by cooling; treating lubricating oils; pitches and paving asphalts; distillation under pressure; storage; etc.

M

MACHINE DESIGN

Kinematics; Use in. Graphic Kinematics in Machine-Tool Design (Zeichnende Kinematik im Werkzeugmaschinenbau), Ferdinand Wittenbauer. Zeit. des Vereines deutscher Ingenieure, vol. 66, nos. 2 and 3, Jan. 14 and 21, 1922, pp. 25–30 and 60-62, 45 figs. Notes on transmission and gears used in machine-tool construction; speed and acceleration of crank gear; slotting machines with quick return of tool; guidance of needles in Wanzer sewing machine; carriage guide for turning pulleys; drive of a high-speed planing machine; oscillating drives by eccentric wheels; oscillating motion of a slot-mortising machine; crank gear with quick-return stroke; oscillating crank guide; steel spring hammers, etc.

MACHINE SHOPS

British. Famous British Works. Eng. Production, vol. 4, nos. 67 and 69, Jan. 12 and 26, 1922, pp.

26-28, 5 figs., and 74-76, 6 figs Jan 12 Describes works of Fielding & Platt, Ltd. Gloucester, for manufacture of hydraulic machinery and gas and oil engines. Jan 26 Works of Geo Richards & Co., Ltd., near Manchester.

Department Layout. Department Layout in the Colburn Shop, Fred H. Colvin Am Mach vol 56, No. 7, Feb. 16, 1922, pp 259-261, 12 figs Arrangements for machining, erecting, and testing units and complete machines. Toolroom arrangement and heat-treating department. Lavatory and coatroom

MACHINE TOOLS

Economical Drives. Efficiency and Fuel Consumption of Factory Installations (Wirkungsgrad und Brennstoffverbrauch von Fabrikanlagen), Karl Meller Zeit fur Dampfkessel u Maschinenbetrieb, vol 44, no 46, Nov 18 pp 369 372, 8 figs Investigation of efficiency of existing installations and how it can be improved with view to saving of coal.

MACHINES

Running Speed and Efficiency. Effect of Acceleration of Running Speed on Increase of Output in Factory Machines (Einfluss der Laufgeschwindigkeit auf die Leistungsteigerung bei Fabrikationsmaschinen), S. Ledermann. Werkstattstechnik, vol 16, no 1, Jan 1, 1922 pp 3-4, 2 figs It is shown that acceleration of speed of machines does not always bring about an increase in performance, but that it is necessary to determine the work time factor.

MAGNESIUM ALLOYS

Electron Metal. Elektron Metal, Adolph Bregman Metal Industry (N. Y.), vol. 20, no. 1, Jan. 1922, pp. 1-3, 9 figs. Discusses composition; physical, chemical and electrical characteristics; fabrication, working soldering and welding; melting and casting, principal uses advantages and disadvantages.

MAGNETOS

Elements. The Functioning of Magnetos (Contribution a l'etude du fonctionnement des magnetos d'allumage), L. Canaby. Arts et Métiers, vol. 74, no. 12, Sept. 1921, pp. 273-281, 13 figs. Discusses the various elements and their influence on working of magneto, gives formulas and curves.

MARINE BOILERS

Economical Operation. Coal Economy at Sea by Improved Methods of Steam Generation, David Brownlie. Shipbuilder, vol. 26, no. 137, 1922 (New Year Number), pp. 49-54, 5 figs Performance of stationary and marine boiler plants; coal weighing; boiler feedwater meters; saving effected by continuous analysis of flue gases.

MECHANICS

Modern Theories. Modern Theories in Mechanics (Les théories modernes de la mécanique), F. Blondel. Révue de l'Industrie Minérale, no. 25, Jan. 1, 1922, pp. 1-21, 12 figs. Discusses Einstein's theory of relativity and experiments leading up to it.

Present Crisis. The Present Crisis in Mechanics (Ueber die gegenwärtige Krise der Mechanik), R. v. Mises. Zeit. für angewandte Mathematik u. Mechanik, vol. 1, no. 6, Dec. 1921, pp. 425-431. Notes on mechanics of the relativity theory. Development of main problem, namely: Can it be assumed that all the phenomena of motion and equilibrium observable in visible bodies can be explained by the Newton and related laws? Development of a scheme of mechanical statistics.

Rigid Frames, Calculation of. Simplified Calculation of Rigid Frames, H. Marx. Mech. Eng., vol. 44, no. 2, Feb. 1922, p. 125, 1 fig. Describes new process devised by H. Bronneck for calculatiog most complicated frame shapes directly and without use of tables. Translated from Dinglers Polytechnisches Jl., vol. 336, no. 21, Oct. 22, 1921, pp. 301-302, 2 figs.

METALS

Cleaning. Industrial Methods of Metal Cleaning, F. MacDonald. Forging & Heat Treating, vol. 8, no. 1, Jan. 1922, pp. 66-70, 6 figs. Cleaning material; equipment for cleaning metal parts; methods.

Failure under Stress. Chemical Influences in the Failure of Metals under Stress, Cecil H. Desch. Faraday Soc. Trans., vol. 17, part 1, no. 49, Dec. 1921, pp. 17-21. Investigation of such instances of intercrystalline rupture as may be attributed to action of chemical reagents.

The Mechanism of Failure of Metals from Internal Stress, W. H. Hatfield. Faraday Soc. Trans., vol. 17, part 1, no. 49, Dec. 1921, pp. 36-46, 7 figs. Discusses influence of cold work, and chemical and corrosive attack. Notes on relative properties of amorphous and crystalline phases of metals, dealing with physical properties (hardness, elasticity, and capacity for plastic deformation) and chemical properties.

Fatigue Failure. Remarks on Fatigue Failure of Metal Parts, their Cause and Prevention, Horace C. Knerr. Forging & Heat Treating, vol. 8, no. 1, Jan. 1922, pp. 40-42, 4 figs. Factors upon which fatigue failure depends are: Number or repetitions; range of stress; presence of points at which stress may be localized. Gives example of fatigue failure.

Hardening. The Slip Interference Theory of the Hardening of Metals, Zay Jefferies and R. S. Archer. Chem. & Met. Eng., vol. 26, no. 6, Feb. 8, 1922, pp. 249-252. General reply to questions raised by various commentators, including condition of iron and carbon in and grain size of martensite.

Internal Stresses. Internal Stresses in Relation to Microstructure, J. C. W. Humfrey. Faraday Soc. Trans., vol. 17, part I, no. 49, Dec. 1921, pp. 47-51, 3 figs. Author offers suggestions, and draws attention to factor in strength of materials which does not appear adequately to have been studied.

Polishing. Motion Study in Metal Polishing Metal Industry (Lond.), vol 20, no 2, Jan 13, 1922, pp 30-33, 3 figs Describes experiment with a wattmeter on the process of roughing.

Season Cracking. The Failure of Metals under Internal and Prolonged Stress, W Rosenhain Faraday Soc Trans., vol. 17, part 1, no. 49, Dec 1921, pp 2-16, 2 figs. Discussion of phenomenon known as season cracking, and consideration of the various explanations therefor.

METRIC SYSTEM

English or Mixed. English, Metric or a Mixed Measurement System. Machinery (Lond.), vol 19, no. 484 Jan 5, 1922, pp. 428-430. Considers relative values of each system in various aspects

MOLDING MACHINES

Air and Electric. Develops Air and Electric Machine Foundry, vol 50, no. 2, Jan. 15, 1922, pp 75 76, 1 fig Air used for ramming sand into molds; but electricity has been adapted for rolling flask and afterward drawing pattern.

Design. The Present Status of Molding-Machine Construction (Der heutige Stand des Formmaschinenbanes), U. Lohse. Zeit. des Vereines deutscher Ingenieure, vol. 66, no. 1, Jan. 7, 1922, pp 4-7, 12 figs Deals with power molding machines, including molding presses and hydraulic molding machines

Equipment and Use. Molding Machine Practice Is Successful, Paul R. Ramp. Iron Age, vol 109, nos 6 and 7, Feb. 9 and 16, 1922, pp. 397-399 and 462-464, 13 figs. Points out that even without castings recurring in large numbers, method may be made to pay. Details of equipment and its use. Marked gain in efficiency in making cylinder and piston molds.

Improvements. Recent Progress in Machine Molding (Neuere Fortschritte in der Maschinenformerei), U. Lohse. Giesserei-Zeitung, vol. 19, nos. 1 and 2, Jan 3 and 10, 1922, pp. 8-12 and 29-32, 9 figs. Describes new arrangements and methods which tend to increase economy of machine molding.

Jarring. Jarring Molding Machines (Étude sur les Machines à mouler à secousses), M. Grospierre. Fonderie Moderne, no. 11, Nov. 1921, pp. 309-316, 5 figs. Discusses principles of machine and describes the Thomas electrically controlled machine working on gravity-magnetic principle. Discussion of paper by M Ronceray, pp. 316-318.

MOLDING METHODS

Gray-Iron Castings. Mold Intricate Gray-Iron Castings, H. E. Diller. Foundry, vol. 50, no. 2, Jan. 15, 1922, pp. 45-51, 11 figs. Describes methods used for molding gas-meter castings and automobile parts, such as flywheels, transmission housings and piston rings.

MOTOR BUSES

Connecticut. The Bus is Finding Its Sphere in Connecticut. Elec. Ry. Jl. (Bus Transportation Section), vol. 59, no. 2, Jan. 14, 1922, pp. 5-13, 2 figs. Gives statistical summary of bus transportation services in state of Connecticut.

Design. Motor Bus and Its Relation to Electric Railways, Ralph M. Sparks. Elec. Ry. Jl. (Bus Transportation Section), vol. 59, no. 2, Jan. 14, 1922, pp. 36-38. Discusses design of motor buses so as to give reliability of service and comfort to passengers, low maintenance cost, and high operating efficiency.

Some Factors Which Must Be Considered in Bus Transportation, Ezra W. Clark. Elec. Ry. Jl. (Bus Transportation Section), vol. 59, no. 2, Jan. 14, 1922, pp. 14-16, 4 figs. Discusses future of bus and its proper design for safety, comfort and efficiency, from standpoints of manufacturing and operating.

Development. Evolution of the Motor Vehicle for Goods and Passenger Service, Percy Frost Smith. Inst. of Transport Jl., vol. 3, no. 1, Nov. 1921, pp. 35-44 and (discussion) pp. 44-47. History of development, and discussion of four principal types, namely, battery, steam, petrol gear-driven and petrol-electric transmission vehicles.

Double-Deck. Details of Equipment and Cost of Operation of Double-Deck Buses in Chicago. Elec. Ry. Jl. (Bus Transportation Section), vol. 59, no. 2, Jan. 14, 1922, pp. 31-36, 11 figs. Describes bus of Chicago Motor Bus Co.; seating capacity, 60; inclosed upper deck.

Overhauling Depot. An Omnibus Overhauling Depot. Engineer, vol. 133, no. 3449, Feb. 3, 1922, pp. 121-124, 19 figs. partly on pp. 130 and 137. Details of large works recently erected by London Gen. Omnibus Co., Ltd., with object of concentrating work of overhauling its vast fleet of motor buses in one building. At least 15 omnibuses are pulled to pieces and re-erected daily. See also Engineering, vol. 113, no. 2927, Feb. 3, 1922, pp. 145-147, 5 figs. partly on p. 140.

MOTOR PLOWS

German Types. Tendencies in German Motor-Plow Construction (Die auf der DLG-Ausstellung sichtbaren Richtlinien des Motorpflugbaues), H. Martiny. Wirtschaftsmotor, nos. 8 and 9, Aug. 10 and Sept. 10, 1921, pp. 29-32 and 31-35, 13 figs. Notes on development and progress, based on observations at exhibition of German Agricultural Soc.

MOTOR TRUCKS

Berliet Chassis. The 25-30 cwt. Berliet Chassis. Motor Transport, vol. 34, no. 880, Jan. 9, 1922, pp. 45-47, 7 figs. Describes French machine designed for heavy work on pneumatic tires which successfully passed very severe French army tests; horsepower rating, 20.1 on R. A. C. formula.

Buying Parts. Buying Parts for a Big Fleet—How a Big Company Economizes Commercial Vehicle, vol 26, no. 1, Feb 1, 1922, pp. 8 9, 3 figs. Describes organization of Consumers Co. of Chicago, which has recently acquired equipment of Cook County Supply Co and its ten subsidiary organizations

German. The German Motor Truck Industry (Die deutsche Kraft Nutzfahrzeug-Industrie), Wirtschaftsmotor, no 8, Aug 10, 1921, pp. 6 19, 47 figs Status and development of German and Austrian motor truck construction. Details and illustrations are given of numerous types of trucks and buses.

Parts Design. Features of Recent Development in Truck Parts Design, P. M. Heldt. Automotive Industries, vol. 46, no 1, Jan. 5, 1922, pp 12 18, 12 figs. Discusses recent developments in engine, clutch, transmission, universal joint, rear axle and wheel design.

Six-Wheeled. Flexible Six-wheelers. Motor Transport, vol. 31, no. 882, Jan 23, 1922, pp. 95 97, 14 figs. Underlying principles of these vehicles, the different types available, and their advantages and possibilities.

MOTORCYCLES

German Types. German Motor Cycles (Deutsche Krafträder und Einbaumotoren), Kurt Bernhard Wirtschaftsmotor, no. 9a, Sept. 25, 1921, pp. 6 11, 61 figs. Details of numerous types, including high-power motor cycles with side carriages; medium- and low-power motor cylces; motor scooters, motor cycles with small non-detachable motors; and non-detachable motors.

N

NICKEL STEEL

Determination of Nickel. The Determination of Nickel in Steel (Nickelbestimmung in verschiedenen Stahlsorten), Hans Rubricius. Chemiker-Zeitung, vol. 46, no. 3, Jan. 7, 1922, p. 26. As result of numerous tests with steels of varying nickel content, it is shown that a complete precipitation of nickel from the ammonia solution can be effected with alcoholic dimethylglyoxim liquid.

Low-Carbon and Chromium. Low-Carbon Nickel and Nickel-Chromium Steels. Iron & Coal Trades Rev., vol. 104, no. 2812, Jan. 20, 1922, p. 77. Summaries of paper on the constitution and properties of low-carbon nickel steels, by J. N. Greenwood, and paper on nickel-chromium steels, by J. S. Dickenson.

O

OIL ENGINES

Solid-Injection. The Solid Injection Oil Engine, C. McTaminey. Mar. Eng. of Can., vol. 12, no. 1, Jan. 1922, pp. 11-14. Describes experiments made on oil tank of the Trefoil, main engines of which are of the four-stroke cross-head type.

OIL FUELS

Ceramic Kilns. Using Liquid Fuel in the Hoffmann Furnaces (L'Emploi des combustibles liquides dans les fours Hoffmann), L. Mascard. Bul. de la Société d'Encouragement pour l'Industrie Nationale, vol. 133, no. 9, Nov. 1921, pp. 1192-1195, 2 figs. Discusses application of heavy oils and tars in ceramic furnaces.

Heavy Oils. Receiving Heavy Fuel Oils (Reception des combustibles liquids lourds), M. Denier. Bulletin Technique du Bureau Veritas, vol. 3, nos. 8, 9, and 10, Aug., Sept. and Oct. 1921, pp. 194-199, 221-227 and 245-251, 28 figs. Aug.: Discusses difficulties of "taking delivery" of mazout, etc., due to various methods of analysis and to its varying composition. Sept.: Discusses laboratory tests, specific gravity, water content, impurities, acidity, cold test flash point, fire point, etc. Oct.: Describes processes and apparatus for various tests, including ignition point, fluidity and viscosity.

OIL PUMPS

Quimby Screw. The Quimby Screw Pump. Shipbldg. & Shipg. Rec., vol. 19, no. 3, Jan. 19, 1922, p. 73. Data on this pump which has been employed in the American naval service as a high-pressure fuel-oil service pump.

OPEN-HEARTH FURNACES

Gun-Steel Manufacture. Acid Open-hearth Process for Manufacture of Gun Steels and Fine Steels, W. P. Barba and Henry M. Howe. Am. Inst. Min & Metallurgical Engrs. Trans., no. 1114-S, 1922, 39 pp., 8 figs., and (in abstract) Min. & Metallurgy, no. 181, Jan. 1922, pp. 32-34. Report of committee appointed during war by Engineering Division of Nat. Research Council to study steel melting and ingot production for guidance of wartime manufacturers. Precautions are given for making the ingots of proper and uniform composition; of proper macro- and micro-structure; sound, that is, free from pipes, blowholes, cracks and roughness; and to prolong life of furnace.

Talbot. The Talbot Process in Comparison with Other Open-Hearth Processes (Das Talbotverfahren im Vergleich mit anderen Herdfrischverfahren), J. Puppe. Stahl u. Eisen, vol. 42, nos. 1 and 2, Jan. 5 and 12, 1922, pp. 1-10 and 46-54, 9 figs. Describes steel works, gas-producer and mixing plants in Witkowitz. Operating conditions of Talbot, Wellmann and ordinary open-hearth furnaces. Technical and economic results obtained with processes carried out in these three furnace types.

OXY-ACETYLENE CUTTING

Cutting Machines. The Godfrey Universal Oxygen-Jet Cutting Machine. Automobile Engr., vol. 11, no. 158, Dec. 1921, pp. 446–447, 4 figs. Built by Godfrey Eng. Works, Lond. Design and operation. Special attention has been given to blowpipe.

OXY-ACETYLENE WELDING

Pipe. Autogenous Pipe Welding, H. B. Iglehart. Power, vol. 55, no. 5, Jan. 31, 1922, pp. 173–174, 4 figs. Account of pratical demonstrations of welded pipe joints made under direction of writer at W. K. Mitchell Co. shops. (Abstract.) Paper read before Int. Acetylene Assn.

Rods for. Welding Rods for Oxy-Acetylene Welding, J. R. Dawson. Iron Age, vol. 109, no. 7, Feb. 16, 1922, pp. 468–472, 17 figs. Also Welding Engr., (vol. 7, no. 1, Jan. 1922, pp. 32, 37 and 40, 17 figs.) under title: Oxy-Acetylene Welding Rods. Their selection and composition as factor in successful results on steel. Welding cast iron. Copper and brass welding. Paper before International Acetylene Assn.

P

PACKING

Transit and Storage. Packing and Wrapping-Up for Transit and Storage (including Baling). Abridgments of Specifications, Period—A.D. 1909-15, class 94 (i), 1921, 221 pp. Patents for inventions.

PAPER MANUFACTURE

Chemical Hydration of Pulp. Chemical Hydration of Pulp, Alfred MacKay. Paper, vol. 29, no. 16, Dec. 21, 1921, pp. 7–10. Discusses hydration of stock by chemical treatment to replace hydration by beating, and gives results of tests carried out showing advatages of chemical hydration.

Fibers for. New Sources of Paper Fibers. Paper, vol. 29, no. 15, Dec. 14, 1921, pp. 20–23. Describes possibilities afforded by giant grasses of India and Africa.

Nigerian Grasses for Paper Making. Imperial Inst. Bul., vol. 19, no. 3, 1921, pp. 271–282. Account of investigation of two series of dried grasses, belonging to ten different species, received by Imperial Inst. from Nigeria in order that their suitability for manufacture of paper might be ascertained.

Laid and Wove Molds. Laid and Wove, Dard Hunter. Paper, vol. 29, no. 16, Dec. 21, 1921, pp. 12–18, 7 figs. Origin of the terms described and their early use set forth.

PAPER MILLS

Construction. Paper Mill Construction, H. S. Taylor. Paper, vol. 29, no. 15, Dec. 14, 1921, pp. 9–11. Discusses engineering as related to pulp and paper industry, plant development, efficiency in operations, organization, etc.

PIPE, STEEL

Centrifugally Cast. Steel Pipe by the Centrifugal Process, L. Cammen. Iron Age, vol. 109, no. 6, Feb. 9, 1922, pp. 405–406. Methods and cost of Cammen process for making seamless pipe at low cost. Competition with welded pipe.

PIPE, WOOD-STAVE

Redwood vs. Fir. Wood-Stave Water Pipe. Pub. Works, vol. 52, no. 1, Jan. 7, 1922, p. 5. Summary of results obtained by its use in U. S. Reclamation projects during past 20 years. Comparison of fir and redwood, buried and above ground.

60-in. Pipe Line. 60-Inch Wood Stave Pipe Line for Hydroelectric Plant, W. A. Scott. Eng. World, vol. 20, no. 2, Feb. 1922, pp. 69–70, 2 figs. New pipe line, 912 ft. long, was built upon a regraded bed and is supported by 166 concrete cradles, each 6 in. thick above ground, with concrete bases 12 in. thick. Staves were creosoted by vacuum process.

POWER PLANTS

Remodeling. Remodeled Naval Proving Grounds Power Plant, P. J. Searles. Power, vol. 55, no. 4, Jan. 21, 1922, pp. 133–134, 2 figs. Describes changes that were made, and gives total cost figures for new boiler, stoker, generator, electrical and auxiliary equipment, etc. Plant was kept in operation while work of remodeling was going on. Explains how difficulty arising in supporting steam pipes was overcome.

POWER TRANSMISSION

Friction Losses. The Problem of Efficient Power Transmission, G. C. V. Hewson. Can. Machy., vol. 27, no. 3, Jan. 19, 1922, pp. 23–26, 8 figs. Friction causes largest percentage of loss; charts and tables showing different conditions.

Industrial Plants. Power Transmission in Industrial Plants, Kenneth M. Raynor. Assn. Iron & Steel Elec. Engrs., vol. 4, no. 1, Jan. 1922, pp. 1–10 and (discussion) 10–21, 5 figs. Discusses construction, operation and some operating results obtained from a 6600-volt, 25-cycle, three-phase balanced-current overhead power transmission loop system operating in a modern steel-mill plant.

PRESSES

Punch, Guard for. Eliminating Cold Trim Press Accidents, G. A. Kuechenmeister. Forging & Heat Treating, vol. 8, no. 1, Jan. 1922, pp. 71–72, 2 figs. After experimenting with various kinds of "two-handed" mechanical tripping devices an electrical guard was installed. Production has not suffered and accidents are eliminated.

Lignite, Preparation of. The Pulverization of Rhenish Lignite (Die Aufbereitung rheinischer Braunkohle zu Staub), H. Weiss and H. Haering. Braunkohle, vol. 20, no. 40, Jan. 7, 1922, pp. 625–631, 4 figs. Describes drying and pulverizing process of the Büttner Works, Inc., Uerdingen on the Rhine; and use of pulverized coal for heating of a recuperative furnace.

Preparing and Distributing System. Preparing and Distributing Powdered Coal, E. C. Greisen. Iron Age, vol. 109, no 5, Feb. 2, 1922, pp. 326–329, 8 figs. Modern seamless steel-tube plant adopts pulverized coal as fuel. Details of system in use for furnaces and boilers.

PUMPS

Boiler-Feed, Governor for. Thermofeed Differential Feed-Pump Governor. Power, vol. 55, no. 5, Jan. 31, 1922, pp. 184–185, 4 figs. Describes device which, when attached to steam supply of pump, will not only cause pump to stop when any predetermined pressure has been attained, but will start pump again as soon as any predetermined drop in pressure has taken place in feed pipe.

PUMPS, CENTRIFUGAL

Corrosive Liquids. The Flexala and Resilene Pumps. Engineering, vol. 113, no. 2925, Jan. 20, 1922, pp. 74–75, 8 figs. Describes centrifugal pumps manufactured by Metal Powders, Ltd., London, feature of which is a flexibility and resilience in certain parts which tend to reduce erosion and corrosion when dealing with acids or liquids holding solids or fibrous matters in suspension.

High- and Low-Lift. The Applications of High- and Low-Lift Centrifugal Pumps. Mech. World, vol. 71, nos. 1829 and 1830, Jan. 20 and 27, 1922, pp. 46–48 and 67–68, 9 figs. Jan. 20: Characteristics of a centrifugal pump; advantages of centrifugal over reciprocating type. Describes De Laval single-stage centrifugal pump having capacity of 10,000 gal. per min. against 150 ft. head. Jan. 27: Discusses boiler feeding and electrically driven centrifugal boiler-feed pumps; circulating pumps for surface condensers barometric and jet condensers.

PYROMETERS

Maintenance Costs. Maintenance Costs of Pyrometric Systems, R. W. Newcomb and G. V. Nightingale. Forging & Heat Treating, vol. 8, no. 1, Jan. 1922, pp. 50–51. Lack of appreciation of sensitivity of pyrometric instruments; thermocouples as high factor in maintenance cost; better protection tubes and care in selection.

Radiation. A New Radiation Pyrometer (Ein neues Strahlungspyrometer). Chemiker-Zeitung, vol. 46, no. 2, Jan. 5, 1922, pp. 20–21, 2 figs. Describes new pyrometer in the shape of a small telescope for use of works engineer in measurement of furnace temperature.

Thermoelectric and Optical. Electrical Instruments for Industrial Measurements, Ezer Griffiths. Beama, vol. 10, no. 1, Jan. 1922, pp. 18–27, 9 figs. Thermoelectric pyrometry and optical pyrometry. Discusses temperature indicators of millivoltmeter type; recording pyrometers; recording potentiometer; automatic temperature control; disappearing filament-type optical pyrometer; and laboratory standard optical pyrometer.

R

RAILS

Basic Bessemer Steel. Basic Bessemer Steel Rails, Cecil J. Allen. Ry. Engr., vol. 43, no. 504, Jan. 1922, pp. 5–8 and 35, 2 figs. Details of modern methods employed in Europe in production of rails by basic bessemer process, including reaction in basic converter, graphic method of estimating additions, comparison of analysis and test results, reliability of basic bessemer steel.

Corrugation. The Corrugation of Tramway Rails. Engineer, vol. 133, no. 3447, Jan. 20, 1922, p. 66, 1 fig. Abstract of report presented to Mun. Tramways Assn. by Rail Corrugation Sub-committee appointed to investigate corrugation of tramway rails, with particular reference to vibration of rails and foundations as cause thereof.

Girder, Rolling. Rolling Girder Rails, R. C. Cram. Elec. Ry. Jl., vol. 59, no 3, Jan. 21, 1922, pp. 102–106, 16 figs Describes the various rolling-mill processes incidental to rolling girder rails; essential difference in rolling T-rails and girder rails; recent developments.

Joint Welding. Reclaiming Joints in Indianapolis, T. H. David. Elec. Ry. Jl., vol. 59, no. 5, Feb. 4, 1922, pp. 199–201. Discusses experience with Lorain weld joints, arc welding on old tracks, and thermit welding. (Abstract.) Paper read before Central Elec. Ry. Assn.

Manufacture. Improvement in the Manufacture of Rails. Ry. & Locomotive Eng., vol. 35, no. 1, Jan. 1922, pp. 6–7. Describes tests made with Hadfield sink-head ingots rolled by Maryland Steel Co., showing that after removal of top discard of 13 per cent, the Hadfield ingot is free from piping and undue segregation.

Standard 7-in. Standard Rails Reduce Costs, R. C. Cram. Aera, vol. 10, no. 7, Feb. 1922, pp. 581–583, 2 figs. Advocates use of Association standard seven-inch girder grooved rail.

RAILWAY CONSTRUCTION

Program. Real Program of Railroad Construction Needed, Herbert Hoover. Ry. Age, vol. 72, no. 6, Feb. 11, 1922, pp. 379–382. Tremendous losses suffered because of lack of foresight and antagonism to railroads.

RAILWAY ELECTRIFICATION

England. The Electrification of English Main Line Railways. Engineering, vol. 113, no. 2926, Jan. 27, 1922, pp. 102–104. Account of discussion held at joint meeting of Instn. Mech. Engrs., Instn. Civ. Engrs. and Instn. Elect. Engrs.

St. Gothard Ry., Switzerland. The Electrification of the St. Gothard Railway. Engineer, vol. 133, no. 3447, Jan. 20, 1922, pp. 68–70, 15 figs. partly on p. 72. Details of electrical equipment of Ritom and Amsteg power stations, locomotive types, etc.

RAILWAY MOTOR CARS

New Haven Branch Lines. New Haven Using Motor Cars on Branch Lines. Ry. Age, vol. 72, no. 5, Feb. 4, 1922, pp. 315–317, 4 figs. Advantages of new passenger-equipment car, including flexibility and low operating cost.

RAILWAY OPERATION

British Railway Speeds. Tables of British Railway Speeds in 1921. Engineer, vol. 133, no. 3449, Feb. 3, 1922, pp. 120–121. Annual statistics.

Train Control. The Control of Trains. Ry. Gaz., vol. 36, no. 3, Jan. 20, 1922, pp. 91–92, 1 fig. Discusses the problem of deceleration and considers brake power in relation to increased weight and speed of trains, combined with reduced headway. Summary of paper read before Instn. Civil Engrs.

RAILWAY REPAIR SHOPS

Freight-Car. Community Hospitals for Disabled Foreign Freight Cars, J. J. Tatum. Ry. Rev., vol. 70, no. 3, Jan. 21, 1922, pp. 73–76, 2 figs. Advocates adequate car facilities at important interchange points on coöperative basis.

RAILWAY SHOPS

Electric Drive for. Electric Drives in Railroad Shops, Bertram S. Pero. Machy. (N. Y.), vol. 28, no. 6, Feb. 1922, pp. 477–481, 10 figs. Selection and types of motors, and application on different kinds of machine tools.

RAILWAY SIGNALING

Interlocking. Interlocking Practice of the Interborough Rapid Transit Ry., W. A. Bartley. Ry. Rev., vol. 70, no. 4, Jan. 28, 1922, pp. 113–115. Describes electropneumatic power interlocking plant and their equipment; traffic density and control, etc. From paper read before N. Y. Sectional Committee.

Light. The Light Signal Committee's Report. Ry. Gaz., vol. 36, no. 3, Jan. 20, 1922, pp. 80–81. Discusses report of departmental committee to Ministry of Transport, who have been inquiring into the potentialities of light signals. Committee favors color light as against position light.

Track Circuits. Testing of D. C. Track Circuits to Insure Safety and Efficiency, F. B. Weigel. Ry. Signal Engr., vol. 15, no. 1, Jan. 1922, pp. 7–9, 2 figs. Discusses limiting resistance at battery; bonding wires; track ballast; track relay and housing. Simple tests should be made periodically. Paper read before A. R. A.

RAILWAY STATIONS

Freight. On the Question of Goods (Freight) Stations, Edilio Ehrenfreund. Int. Ry. Assn. Bul., vol. 4, no. 1, Jan. 1922, pp. 5–24, 11 figs. Report No. 2 (Italy). Organization of receiving and delivering stations, so as to accelerate their business. Arrangement of building and tracks so as to simplify shunting (switching) operations and handling. Mechanical appliances.

On the Question of Good (Freight) Stations, M. Jullien and M. Moutier. Int. Ry. Assn. Bul., vol. 4, no. 1, Jan. 1922, pp. 151–192, 12 figs. Report No. 1 (All countries, except Italy and those using English language.) Organization of receiving and delivering stations, so as to accelerate their business. Arrangement of buildings and tracks so as to simplify shunting (switching) operations and handling, particularly as regards goods in bulk. Mechanical appliances.

RAILWAY TIES

Specifications. Procurement of Railway Ties Under Federal Control, G. G. Yeomans. Ry. Rev., vol. 70, nos. 1 and 2, Jan. 7 and 14, 1922, pp. 20–22 and 55–57. Work of the Forest Products Section. Standard tie specification most notable achievement. Describes control and distribution of all wood preservatives, together with work involved in procurement of lumber required for construction of Railroad Administration freight cars.

Treatment. Wood Preservers Discuss Economics of Ties. Ry. Age, vol. 72, no. 4, Jan. 28, 1922, pp. 269–271, 1 fig. Factors affecting cost of treated cross ties. Economics of tie renewals. Papers read before Am. Wood-Preservers' Assn.

RAILWAY TRACK

Maintenance. On the Question of the Maintenance and Supervision of the Track, Joseph Barbierint. I. Ry. Assn. Bul., vol. 4, no. 1, Jan. 1922, pp. 139–150. Report No. 4 (All countries, except Great Britain and America.) Measures to be taken to provide an economic organization for maintenance and supervision of track, taking into consideration increase of traffic and speed as well as rise in wages and in cost of materials. Use of mechanical appliances.

Relocation. Costly Railroad Re-location. Cement & Eng. News, vol. 34, no. 2, Feb. 1922, pp. 23–24, 2 figs. Shifting 15 miles of double-track railroad around Huffmann dam, Miami Conservancy District, required excavating 657,000 yd., mostly rock in one cut 120 ft. deep, placing 390,000 yd. embankment. Cost more than $3,237,000.

Relocation on the South African Government Railways. Eng. News-Rec., vol. 88, no. 3, Jan. 19, 1922, pp. 116-118, 4 figs. A 70-mi. relocation in rough country, reducing curvature 50 per cent and maximum grades from 3.3 to 1.5 per cent, is being carried out on S. A. Government Railways to meet requirements of increasing traffic.

Roadbed Construction. On the Question of the Construction of the Road Bed and of the Track, M. Henry and M. Candelier. Int. Ry. Assn. Bul., vol. 4, no. 1, Jan. 1922, pp. 251-270, 11 figs. Supp. to Report No. 2 (Oct. 1920, p. 639) (All countries, except Denmark, Sweden, Norway, Great Britain and America.) Arrangements to be adopted, in view of increase in locomotive weight and speed of trains.

RAILWAY YARDS

Terminals and. Report of Committee XIV—On Yard and Terminals. Am. Ry. Eng. Assn. Bul., vol. 23, no. 239, Sept. 1921, pp. 65-84. Warehouses in connection with L. C. L. freight houses. Classification yards, including methods of switching from classification to departure yards.

RAILWAYS

Light. Development of Light Railways in Great Britain. Eng. News-Rec., vol. 88, no. 5, Feb. 2, 1922, p. 205. Standard gage preferable; or 30-in. for isolated lines. Light rail and load; economic operation; road motors.

Net Cost of Transportation. On the Question of the Net Cost, Rates, Samuel O. Dunn. Int. Ry. Assn. Bul., vol. 4, no. 1, Jan. 1922, pp. 123-138. Report No. 3 (America). Determination of net cost of carriage (passengers and goods), taking capital charges into consideration. Relation to rates charged.

REFRIGERATING MACHINES

Modern Types. The Present Status of Design of Refrigerating Machines (Der heutige Stand des Kältemaschinenbaues), Martin Krause. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 52, Dec. 24, 1921, pp. 1349-1355, 25 figs. Notes on working process of superheated compressor in ammonia machines. Present design of compressors and condensers. Improvement of carbonic-acid machines using hot cooling water by increasing liquid pressure. Steam refrigerating machines for low brine temperatures and high refrigerating capacities.

REFRIGERATING PLANTS

Ammonia Condensers. Types and Constructions of Ammonia Condensers. Power, vol. 55, no. 6, Feb. 7, 1922, pp. 208-210, 7 figs. Discusses principles of operation of several condensers in general use.

Economy in. Refrigerating Plant Economy Standards and Records, Victor J. Azbe. Ice & Refrigeration, vol. 62, no. 1, Jan. 1922, pp. 19-21. Discusses basic requirements of an efficient plant, including, lowest possible condenser pressure and highest possible back pressure, highest possible CO_2 and lowest possible flue-gas temperature, etc. Paper read before Nat. Assn. Practical Refrig. Engrs.

REFRIGERATION

Carbonic-Dioxide Refrigerating Cycle. The Carbonic Refrigerating Cycle, H. J. Macintire. Power, vol. 55, no. 5, Jan. 31, 1922, pp. 175-177, 2 figs. Presents latest table on properties of saturated carbon dioxide, which is said to be great improvement over previous tables, and diagram known as total-heat diagram, showing effect of condensation or liquefaction of carbon dioxide and condition of substance.

Forecooling Liquid Ammonia. Forecooling of Liquid Ammonia, H. T. Whyte. Ice & Refrigeration, vol. 62, no. 1, Jan. 1922, p. 15. Discusses different methods. Paper read before Nat. Assn. Practical Refrig. Engrs.

Wet vs. Dry Compression. Wet vs. Dry Compression, Van. R. H. Greene. Ice & Refrigeration, vol. 62, no. 1, Jan. 1922, pp. 10-11. Objection to wet compression; maximum output for minimum of power; etc. Paper read before Nat. Assn. Practical Refrig. Engrs.

RIVETING

High-Speed Hammers. Cutting Costs with Riveting Hammers, Fred R. Daniels. Machy. (N. Y.), vol. 28, no. 6, Feb. 1922, pp. 474-476, 6 figs. Several examples of cold-heading and rivet-setting operations performed on high-speed riveting hammers made by the High Speed Hammer Co., Inc., Rochester, N. Y., are illustrated.

ROLLING MILLS

Cross. Cross-Rolling Mills. Eng. Progress, vol. 3, no. 1, Jan. 1922, pp. 4-6, 12 figs. Discusses mode of action and field of application, and describes the Friemel cross-rolling mill.

Sheet Mills. Sheet Mill of the Otis Steel Company. Iron Age, vol. 109, no. 4, Jan. 26, 1922, pp. 259-263, 6 figs. Features include staggered arrangement of furnaces. Powdered coal used. Plant notable for its applications of modern equipment and design.

Strip-Rolling Calculations. Cold Rolled Strip Steel Calculations, S. T. Hilliard. Iron Age, vol. 109, no. 4, Jan. 26, 1922, pp. 267-268. Formulas for determining pounds output and piece-work rates in manufacture of cold rolled strip steel.

RUBBER

Energy-Absorbing Capacity. Energy Absorbing Capacity of Vulcanized Rubber, H. P. Gurney and C. H. Tavener. Jl. Indus. & Eng. Chem., vol. 14, no. 2, Feb. 1922, pp. 134-139, 36 figs. Discusses relations which exist between capacity of vulcanized rubber to absorb or store up in a potential form and partially to transform or degrade kinetic energy into heat when subjected to single or repeatedly applied stresses.

S

SAND, MOLDING

Origin and Uses. Moulding Sands: Their Origin and Uses, Alexander Scott. Mech. World, vol. 71, no. 1830, Jan. 27, 1922, pp. 71-72. Discusses uses of sands as abrasives, for casting molds and surface linings, building purposes, an ingredient of soap, and as a filtering medium in connection with water supplies. From paper read before Stoke Assn. of Engrs.

SCALES

Precision Tests. The Precision Test of Large Capacity Scales. Scale Jl., vol. 8, no. 4, Jan. 10, 1922, p. 6, 1 fig. Gives extract from Technologic Paper 199 of Bur. of Standards, which outlines procedure for accurate test.

SCIENTIFIC MANAGEMENT

See INDUSTRIAL MANAGEMENT.

SCRAP

Non-Ferrous, Smelting. The Smelting of Scrap Metal (Einschmelzen von Metallabfällen), F. Reinboth. Metall-Technik, vol. 47, no. 4, Mar. 9, 1921, pp. 21-23. Suggestions for smelting of aluminum, copper, brass, nickel, zinc and rare-metal scrap.

SEAPLANES

Fairey Long-Distance. The New Fairey Long-Distance Seaplane. Flight, vol. 14, no. 3, Jan. 19, 1922, pp. 35-36, 3 figs. Top speed developed was 95 m.p.h. with a power load of over 19 lb. per hp., and a wing loading of over 10 lb. per sq. ft. Rolls-Royce "Eagle" engine.

SEMI-DIESEL ENGINES

Peugeot. The Peugeot Semi-Diesel Engine. Motor Transport, vol. 34, no. 882, Jan. 23, 1922, pp. 99-102, 12 figs. Describes two-cylinder two-stroke motor of original design which is being put into service in Paris by General Omnibus Co.

Vickers-Petter Manufacturing Methods. Semi-Diesel Engine Construction. Eng. Production, vol. 7, nos. 66 and 67, Jan. 5 and 12, 1922, pp. 13-19 and 37-41, 29 figs. Describes works practice of Vickers-Petters, Ltd.

SEMI-STEEL

Elongation and Compression. Elastic Limits of Elongation and Compression of Semi-Steel (Limites élastiques a la Traction et a la Compression de la Fonte aciérée), M. Portevin. Fonderie Moderne, no. 11, Nov. 1921, pp. 321-324, 5 figs. Gives results of tests from which curves are plotted and formula developed.

SHAPERS

Vertical. Production Work on Vertical Shapers, Edward K. Hammond. Machy. (N. Y.), vol. 28, no. 6, Feb. 1922, pp. 483-485, 5 figs. Operations advantageously performed on shapers of vertical type.

SILICA BRICK

Breakage Factor in Manufacture. Breakage Factors in Silica Brick Manufacture, Philip H. Jung. Chem. & Met. Eng., vol. 25, no. 5, Feb. 1, 1922, pp. 214-217. Critical discussion of those factors in manufacture of silica brick which determine breakage records; properties of silica rock; grinding; effect of bats; workmanship; drying; setting in kiln; burning; methods of firing.

South Wales Silica. The Refractory Silica Materials of South Wales, W. R. D. Jones. Colliery Guardian, vol. 123, no. 3181, Jan. 6, 1922, p. 11. Discusses importance of texture and correct grading of materials employed in silica brick manufacture; also refractoriness.

SPRINGS

Helical, Calculation of. Practical Helical Spring Calculation, Alex Taub. Am. Mach., vol. 56, no. 5, Feb. 2, 1922, pp. 179-183, 2 figs. Essentials of spring design. Analyzing spring troubles mathematically.

STANDARDIZATION

Basic Standards. Development and Construction of Standard Parts Making Use of Basic Standards (Entwicklung und Aufbau von Normteilen unter Benutzung von Grundnormen), R. Koch. Betrieb, vol. 4, no. 7, Jan. 14, 1922, pp. 83-89, 21 figs. It is shown on two definitely established standard parts that even the simplest standard part is composed of different individual standards, and on screwed pipe joints and plug cocks that a systematic development of suitable basic standards is of great advantage in standardization. Report of German Industry Committee on Standards (NDI).

Germany. Industrial Standardization in Germany. Mech. Eng., vol. 44, no. 2, Feb. 1922, pp. 136-137. Describes program being carried out in Germany. Organization and methods of work; work in special industries; system of "preferred numbers."

Importance. Significance of Standardization, A. A. Stevenson. Am. Mach., vol. 56, no. 4, Jan. 26, 1922, pp. 138-139. Points out need for coöperation between industry and Federal Government. Work of committees in harmonizing conflicting standards and formulating new ones. (Abstract.) Paper presented before Am. Eng. Standards Committee.

STANDARDS

German N. D. I. Report. Report of the German Industry Committee on Standards (Normenausschuss der Deutschen Industrie). Betrieb, vol. 4, no. 6, Dec. 24, 1921, pp. 73-77, 4 figs. Proposed standards for fastening of belt pulleys on transmission shafts, and for ball hand cranks. Problems of the working committee for screws.

STEAM

Generation and Utilization. Fuel Economy by the Adoption of Scientific Management in Steam Generation and Utilisation, David Brownlie. Eng. & Indus. Management, vol. 7, nos. 2, 4 and 5, Jan. 12, 26 and Feb. 2, 1922, pp. 39-41, 6 figs., 117-120, 9 figs. and 131-132, 2 figs. Jan. 12: Boiler and pipe coverings. Jan. 26 and Feb. 2: Steam traps.

STEAM ENGINES

Compound Drop-Valve. Compound Drop-valve Mill Engine. Mech. World, vol. 71, no. 1827, Jan. 6, 1922, pp. 11-12, 3 figs. Describes cross-compound jet-condensing type of engine, having cylinders 27 in. and 55 in., with a 5-ft. stroke, built by Hick, Hargreaves & Co., Bolton. Develops 1580 i.hp. at 65 r.p.m.; boiler pressure, 160 lb.

Schmidt High-Pressure. Schmidt Steam Engine More Efficient Than Largest Turbine, O. H. Hartman. Power, vol. 55, no. 6, Feb. 7, 1922, pp. 217-219, 2 figs. Results of tests indicate that it is feasible to generate and utilize steam at pressure of 800 lb. per sq. in. and over in reciprocating engines with probable gain of 20 per cent in efficiency as compared to best present-day turbine practice. Steam consumption of 5.12 lb. per i.hp. was obtained with 150-hp. engine. Translated from Zeit. des Vereines deutscher Ingenieure.

Uniflow. Modern Development of Uniflow Steam Engines (Die neuere Entwicklung der Gleichstromdampfmaschine), H. Bonin. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, no. 46, Nov. 18, 1921, pp. 372-374, 4 figs. Describes various working losses occurring in a reciprocating steam engine, and shows how these losses can be greatly reduced in a uniflow engine. Report of new edition of book entitled, Uniflow Steam Engines, by J. Stumpf.

300-HP. Uniflow Engine. Engineering, vol. 113, no. 2927, Feb. 3, 1922, p. 136, 7 figs. partly on p. 137. Describes engine recently constructed under John Davidson's patents by Clayton, Goodfellow and Co., Ltd., Blackburn, England. It has a single-cylinder, 24-in. diam. by 30-in. stroke, and operates with steam at 160 lb. per sq. in. and 150 deg. fahr. superheat.

STEAM METERS

Kent-Hodgson. The Kent-Hodgson Steam Meters, J. L. Hodgson. So. African Eng., vol. 32, no. 12, Dec. 31, 1921, pp. 243-245, 5 figs. Describes steam meter developed by the author and his firm (George Kent, Ltd., Lond.). Used in power stations and paper mills, collieries and cement works, due works and pumping stations, on locomotives and on ship board.

STEAM PIPES

Economical Diameter. The Most Economical Pipe Diameter for Steam Piping (Der billigste Rohrdurchmesser für Kraftdampfleitungen), O. Denecke. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, no. 49, Dec. 9, 1921, pp. 394-396, 1 fig. Determination of diameter taking only pipe friction into consideration; and taking the separate resistances into consideration; the cheapest diameters. Numerical example with high-pressure saturated-steam turbine.

STEAM POWER PLANTS

Auxiliary Drives. Driving Power-House Auxiliaries, W. H. Smith. Power, vol. 55, no. 5, Jan. 31, 1922, pp. 166-169, 3 figs. Types of auxiliary drives; heat-balance considerations that influence selection of drives; a.c. versus d.c. motors; suitable voltage for auxiliary motors; selection of motors for various drives.

Birmingham, Ala. Sloss-Sheffield Steel and Iron Company's Steam Generating Stations, M. M. Argo and H. Maulshagen. Blast Furnace & Steel Plant, vol. 10, no. 1, Jan. 1922, pp. 83-88, 14 figs. Describes their modern steam-generating plants at North Birmingham, Ala., including feedwater system and by-product power house.

STEAM TURBINES

Blade Proportioning. The Proportioning of Steam Turbine Blading, Harold Medway Martin. Engineering, vol. 113, nos. 2923, 2924, 2925, 2926 and 2927, Jan. 6, 13, 20, 27 and Feb. 3, 1922, pp. 1-3, 33-34, 66-70, 96-98 and 128-130, 14 figs. Determination of effective thermodynamic head and general dimensions of a compound turbine to operate with given indicated hydraulic efficiency; also relation between thermodynamic head and specific volume.

Increasing Efficiency. Possibilities of the Turbine, P. F. Coffin. Power, vol. 55, no. 4, Jan. 24, 1922, pp. 136-137, 1 fig. Points out that efficiency limitations reached in steam turbines may be overcome by using two vapors in series, such as mercury and steam. A 1000-kw. experimental unit has operated under conditions equivalent to producing 1 kw-hr. on about 11,300 B.t.u. (Abstract.) Author's contribution, "Utilization of Coal on a Multiple-Products Basis," to R. F. Bacon's and W. A. Hamor's forthcoming book, "American Fuels."

STEEL

Alloy. See ALLOY STEELS.

Boiler-Tube. Occurrence of Oxides and Nitrides in Boiler Tube Steel, A. E. White and J. S. Vanick. Am. Soc. for Steel Treating Trans., vol. 2, no. 4, Jan. 1922, pp. 323-330, 8 figs. Discusses examination of boiler tube which has been overoxidized, or allowed to absorb and retain an excess of oxygen and nitrogen.

Casting Ingots. Leaves from a Steel Melter's Note Book, Henry D. Hibbard. Iron Age, vol. 109, no. 7, Feb. 16, 1922, pp. 465-467. Experiences in casting

1860-1922

In our sixty-two years of bearing service to the railroads, power plants, industrial plants and manufacturers of America not one pound of anything but the finest procurable virgin material has ever been permitted to enter our metals. We have never used, and will not use, reclaimed or scrap metal of any kind.

During this sixty-two years we have not, to our knowledge, lost a single customer because of failure of our metal or for lack of uniformity. Three of the largest corporations in the United States have been our customers continuously for more than fifty years, several for more than thirty years, many for more than ten years.

For the past thirty years our metals have been alloyed by the process developed by the late A. W. Cadman. This process, by ensuring perfect distribution of the hardening medium, greatly increases the life of the bearing and removes the common causes of bearing trouble.

We cannot afford to ignore for one instant the traditions which make the name Cadman on a bearing metal a guarantee of perfect bearing service.

Can you?

steel ingots in cans How cracks were prevented Causes of hard spots in forging ingots.

Chrome. See CHROME STEEL.

Chrome-Nickel. See CHROME-NICKEL STEEL.

Fracture. Intercrystalline Fracture in Steel, D Hanson. Faraday Soc. Trans., vol. 17, part 1, no. 49, Dec. 1921, pp. 91–101, 13 figs. Discusses cases of failure which occur only under certain circumstances, in material of normal quality, when time during which stress is applied is prolonged.

Internal Service Strains. Internal Service-Strains in Steel, James E. Howard. Faraday Soc. Trans., vol. 17, part 1, no. 49, Dec. 1921, pp. 117 122. Deals particularly with original properties and characteristics of steels, and means by which these original properties are modified.

Nickel. See NICKEL STEEL.

Nitrogen in. The Determination of Nitrogen in Steel, Frederik Hurum and Henry Fay. Chem. & Met. Eng., vol. 25, no. 5, Feb. 1, 1922, pp. 218–222, 2 figs. Review of literature on the subject. Describes reagents and apparatus recommended for determination of nitride nitrogen.

STEEL, HEAT TREATMENT OF

Cost Analysis. Over-all Cost of Heat-Treated Parts, C. I. Ipsen. Iron Age, vol. 109, no. 7, Feb. 16, 1922, pp. 459–462, 6 figs. Electric current or fuel cost is only a portion of total cost. Percentage of rejection important. Cost of subsequent operations an item.

Effect on Properties. The Effect of Heat Treatment on the Properties of Steel, G. L. Thirkell. Commonwealth Engr., vol. 9, nos. 3 and 4, Oct. 1, and Nov. 1, 1921, pp. 69–74 and 109–114, 28 figs. Describes the iron-iron-carbide diagram. Notes on heating and cooling curves, effect of carbon on the change points, effect of heat on grain size, hardening and tempering.

Medium-Carbon Steel. Effect of Time in Reheating Quenched Medium-carbon Steel Below the Critical Range, Carle R. Hayward, Daniel M. MacNeil and Raymond L. Presbrey. Am. Inst. Min. & Metallurgical Engrs. Trans., no. 1111-S, 1922, 5 pp., 2 figs., and (in abstract) Min. & Metallurgy, no. 181, Jan. 1922, pp. 34–35. Results of investigation show that even 5 min. heating at 300 deg. cent. lowers considerably the strength and hardness and increases ductility; there is marked increase in ductility in passing from 400-deg. to 500-deg. treatment without equivalent lowering of strength; specimens reheated to 600 deg. cent. are nearly as ductile as annealed specimens, but have an elastic limit about 60 per cent greater.

Ordnance Purposes. Heat Treatment of Steel for Ordnance Purposes, H. F. Leary. Am. Soc. for Steel Treating Trans., vol. 2, no. 4, Jan. 1922, pp. 288–295. Discusses specification requirements for gun forgings so far as heat treatment is concerned.

STEEL, HIGH-SPEED

American Manufacture. American Practice in High-Speed Steel Manufacture, A. H. d'Arcambal. Chem. & Met. Eng., vol. 25, no. 24, Dec. 14, 1921, pp. 1097–1099, 3 figs. Impressions received on trip of inspection covering several plants. Importance of pure raw materials and metallurgical control of all steps in process is emphasized.

STEEL WORKS

Holland. Royal Dutch Blast-Furnaces and Steel Works in Course of Construction (De in aanbouw zijnde werken ven de Koninklijke Nederl. Hoogovens en Staalfabrieken), A. H. Ingen Housz and A. H. Van Rood. Ingenieur, vol. 37, no. 1, Jan. 7, 1922, pp. 1–12, 12 figs. Discusses work of committee for installation of a plant comprising blast furnaces, steel works and rolling mills, and describes construction of works at Kaaimuur.

STOKERS

Underfeed, Operation of. The Practical Operation of an Underfeed Stoker. Power, vol. 55, no. 5, Jan. 31, 1922, pp. 179–180, 3 figs. Article, based on actual experience with type AA 4 Taylor stoker, covers following subjects: Starting up; regulating draft and stoker speed; proper thickness and contour of fire; use and misuse of long stroke of lower ram; getting rid of troublesome clinkers; dumping ash; keeping lower ram from binding.

STREET RAILWAYS

Track Paving. The Pavement of Tracks in Street Railways Laid in Asphalt Roads (Befestigung der Gleisstreifen bei Strassenbahnen in Asphaltfahrstrassen), H. Henneking. Verkehrstechnik, vol. 39, no. 1, Jan. 6, 1922, pp. 4–6, 7 figs. Describes paving of track in Magdeburg, Germany. Roadbed between outside rails is covered with copper slag bricks on gravel base, and on either side of outside rail is a 50-cm. strip paved with copper slag bricks on concrete base with asphalt grouting of joints.

STRESSES

Concentrations Due to Notches. Stress Concentrations Due to Notches and Like Discontinuities, E. G. Coker and Paul Heymans. Engineering, vol. 113, no. 2923, Jan. 6, 1922, pp. 26–28, 6 figs. Brief account of experimental investigations made on discontinuities by photoelastic methods described in previous report, whereby stress distributions have been determined sufficiently completely to allow of fairly accurate value being assigned to maximum stresses experienced under given loads. (Abstract.) Report on Complex Stress Distribution, read before British Assn. at Edinburgh.

STRUCTURAL STEEL

Joints of Rigid Members. Tests on Joints of Rigid Members (Versuche mit Anschlüssen steifer Stäbe). H. Rudeloff. Zeit. des Vereines deutscher Ingenieure, vol. 66, no. 3, Jan. 21, 1922, pp. 68–69, 1 fig. Results of tests conducted at the State Material-Testing Bureau, Berlin-Dahlem, on rigid bars of angle and channel iron. (Abstract.) Berichte des Ausschusses fur Versuche im Eisenbau des deutschen Eisenbauverbandes, no. 3.

SUBSTITUTE MATERIALS

Germany. The Utilization and Improvement of German Raw Materials (Ausnutzung und Veredlung deutscher Rohstoffe), H. Schulz Zeit. des Vereines deutscher Ingenieure, vol. 66, no. 2, Jan. 14, 1922, pp. 37–42. Review of Prof. Kessner's book with above title, giving his experiences during war in use of German raw materials, with discussion of future utilization of these experiences. Deals with use of substitute materials for overhead lines, cables, insulated wirings, motors and transformers, etc.; substitute materials in general machine construction; fiber materials, graphite, lubricants, etc.

T

TEMPERATURE MEASUREMENT

Ardometer. The Ardometer, a New Measuring Instrument for High Temperatures (Ein neues Messgerät für hohe Temperaturen: das "Ardometer"), G. Quaink. Dinglers polytechnisches Jl., vol. 336, no. 23, Nov. 19, 1921, pp. 323–325, 5 figs. Describes new instrument by Siemens & Halske, which is said to combine advantages of the thermoelectric and the light-radiation pyrometers, and is especially adapted to measurment of internal temperatures of furnaces.

Ultra-Micrometer. The Application of the Ultra-Micrometer to the Measurement of Small Increments of Temperature, W. Sucksmith. Lond. Edinburgh and Dublin Philosophical Mag. & Jl. Sci., vol. 43, no. 253, Jan. 1922, pp. 223–226, 2 figs. Method used was to attach a metal bar to one of two opposite condenser plates and measure change in temperature by change in note produced in telephone.

TEXTILE MACHINERY

Flax-Stripping Machine. The Feuillette Flax Stripping Machine (Machine, système Feuillette, pour le teillage industriel du lin), E. Weiss. Le Génie Civil, vol. 79, no. 27, Dec. 31, 1921, pp. 590–591, 6 figs. Describes machine and its operation, and the process of stripping.

Manufacture. Building Textile Machinery. Eng. Production, vol. 4, no. 70, Feb. 2, 1922, pp. 109–114, 14 figs. Manufacturing methods and equipment of The British Northrop Loom Co., Ltd., Blackburn.

THERMIT WELDING

Joining Bars. Joining Bars by Thermit Welding, L. I. Grinnell. Am. Mach., vol. 56, no. 4, Jan. 26, 1922, pp. 132–133, 6 figs. Long bars needed for making lead screws of rifling machines; aligning the sections; making mold and weld.

TUBES

Brass, Internal Stresses in. Internal Stresses in Brass Tubes, H. N. Vaudrey and W. E. Ballard. Faraday Soc. Trans., vol 17, part 1, no. 49, Dec. 1921, pp. 52–57, 7 figs. Deals exclusively with brass tubes of circular section containing about 70 per cent of copper.

Elliptic, Thickness of. Thickness of Elliptic Tubes (Épaisseur d'un tube elliptique), Gay Georges and Gay Albert. Annales de l'Énergie, vol. 1, no. 6, Nov.-Dec. 1921, pp. 217–219. Calculation based on resistance of materials.

U

UNEMPLOYMENT

Causes and Remedies. The Unemployment Problem. Nat. Indus. Conference Board, research report no. 43, Nov. 1921, 91 pp., 9 figs. Deals with extent, causes and suggested remedies for unemployment.

Insurance Scheme. Unemployment Insurance With Special Reference to Individual Firms and Industries, Henry Lesser. Jl. Indus. Administration, vol. 1, no. 8, Dec. 1921, pp. 227–239. Discusses a scheme for administration of unemployment insurance in individual firms, with ultimate object of its expansion and application to each organized industry as a separate, self supporting entity. (Abstract.) Paper read before Inst. Indus. Administration.

V

VALVE GEARS

Governor-Controlled. The Most Favorable Motion of Governor-Controlled Valve Gear (Ueber die günstigste Bewegung zwangläufig gesteurter Ventile), W. Borth. Wirtschaftsmotor, no. 7, July 1921, pp. 15–19, 10 figs. Writer discusses theoretical conditions for the best valve motion and seeks to establish most favorable lift curve.

Reversing. Reversing Gears (Ueber Umsteuerungen) W. Jung. Zeit. fur angewandte Mathematik u. Mechanik, vol. 1, no 6, Dec. 1921, pp. 455–463, 17 figs. Discusses different types of reversing gear, including the Stephenson gear favored in rolling-mill engines, and a more recent American reversing gear, the Baker Pilliod.

VALVES

Gate, Loss of Head in. Experiments Show Measurement of Valve Loss Dependent on Piezometer Location, Charles I. Corp. Wis. Engr., vol. 26, no. 4, Jan. 1922, pp. 61–62, 4 figs. Describes experiments carried out to determine loss of head due to flow to water.

Johnson-Boving. The Johnson-Boving Valve. Engineering, vol. 113, no. 2923, Jan. 6, 1922, p. 24, 4 figs. Describes large valves constructed by Glenfield & Kennedy, Ltd., Kilmarnock, England, consisting of a cylinder which, when valve is closed, rests against a seating in the main, and, when valve is open, is telescoped back into a casing so as to have a large free waterway.

VENTILATION

Katathermometers. Ventilation and Human Efficiency, Leonard Hill. Mech. World, vol. 71, no. 1830, Jan. 27, 1922, p. 69. Better health due to attention to good ventilation, and increase in efficiency and output due to cooling power adjusted to severity of work. Notes on electric and recording katathermometers. From paper read before Instn. Min. & Met.

W

WAGES

Piece-Price Systems. Should Piece-Price Systems Be Abandoned? James H. Delany. Factory, vol. 28, no. 2, Feb. 1922, pp. 175–176, 2 figs. Writer tells why he believes that piece-price systems should be scrapped and how scrapping will bring lower wages without cutting piece rates.

WASTE ELIMINATION

Research and. Elimination of Waste in Industry Through Research, F. A. Wardenburg. Mech. Eng., vol. 44, no. 2, Feb. 1922, pp. 115–116. Outlines plan of a large corporation. Suggests coöperative plan. (Abstract.)

WASTE HEAT

Utilization. Heat Utilization and Economy in Steam Power Plants (Wärmeausnutzung und Wirtschaftlichkeit in Dampfkraftanlagen), W. Graulich. Chemiker-Zeitung, vol. 45, no. 153, Dec. 22, 1921, pp. 1233–1238. Study of waste-heat utilization Notes on volume of heat required for generation of steam; arrangements for utilization of waste-heat energy; purpose and limitations of waste-heat utilization.

The Utilisation of Waste Heat in Generating Stations. Electrician, vol. 88, no. 2280, Jan. 27, 1922, pp. 94–95, 2 figs. Abstract of paper by Ingham Haden suggesting combination of heat distribution in form of steam or hot water with electrical generation so as to utilize our fuel resources to better advantage, effected by converting generating stations, which would otherwise be discarded, into heat stations, and of paper by F. H. Whysall dealing with practical and economic difficulties of such a scheme. Read before joint meeting of Instn. Elec. Engrs. and Instn. Heat. & Vent. Engrs. See also editorial on pp. 90–91.

Utilization of Waste Heat. Eng. & Indus. Management, vol. 7, no. 4, Jan. 26, 1922, pp. 102–105, 2 figs. Suggests combination of heat distribution with generation of electric current as possible means of using coal to better advantage. Based on paper presented before (British) Instn. Elec. Engrs. by V. Ingham Haden.

WELDING

Locomotive Boilers. Locomotive Boiler Welding. Welding Engr., vol. 7, no. 1, Jan. 1922, pp. 26–28, 19 figs. Special committee of Master Boiler Makers' Assn. reports best methods of reconditioning boilers. To be presented before Master Boiler Makers' Assn. convention.

Wire Specifications. Welding Wire Specifications and Folios. Am. Welding Soc., Bul. no. 1, Dec. 1921, 16 pp. Report of committee.

[See also ELECTRIC WELDING, ARC; FUSION WELDING; OXY-ACETYLENE WELDING; THERMIT WELDING.]

WELDS

Test Standards. Committee Recommends Standards for Tests of Welds. Automotive Industries, vol. 46, no. 1, Jan. 5, 1922, pp. 19–20, 6 figs. Describes the shop, commercial and research standards of tests which Am. Bur. of Welding committee finds are desirable.

Standards for Testing Welds. Am. Welding Soc., Bul. no. 1, June 1921, 16 pp., 14 figs. Report of committee.

WINCHES

Pneumatic. Comparative Tests on Pneumatic Winches (Vergleichende Versuche an Presslufthaspeln), M. Schimpf. Glückauf, vol. 57, no. 51, Dec. 17, 1921, pp. 1245–1249, 9 figs. Results of tests on described machines are numerically and graphically compared. Points to necessary dewatering of compressed air underground and shows that through increasing temperature of compressed air at point of consumption, great savings can be effected.

WIND TUNNELS

Design and Equipment. The New Four-Foot Wind Tunnel at the Massachusetts Institute of Technology, William H. Miller and John R. Markham. Aerial Age Weekly, vol. 14, no. 20, Jan. 23, 1922, pp. 472–473, 4 figs. Describes construction and equipment of two new tunnels, one having a 4-ft. and the other a 7 $^1/_2$-ft. diameter.

Motor Regulators and Manometer. Langley Field Wind Tunnel Apparatus, D. L. Bacon. Aerial Age Weekly, vol. 14, no. 22, Feb. 6, 1922, pp. 518–519, 2 figs. Deals with regulators for speed of wind-tunnel drive motor; and a Vernier manometer with adjustable sensitivity. Technical Note, Nat. Advisory Committee for Aeronautics.

MECHANICAL ENGINEERING

Volume 44 May, 1922 Number 5

Power Development in the Southeast

Utilized and Undeveloped Water-Power Resources of Five Southern States Discussed—Present State of Muscle Shoals Project and Future Possibilities Described

By CHAS. G. ADSIT,[1] ATLANTA, GA.

In considering the power development in the Southeast, it is perhaps in order to give a brief history of the development and use of hydroelectric power since this form of energy predominates in this section.

It has been found that some form of water wheel was in use with primitive peoples as far back as any record is available, the first ones raising water for irrigation and for grinding grain. Water wheels have gone slowly through the various steps of development from these early times, but it was not until their application to driving electric generators that improvement of design and efficiency began. Since that time, they have grown from a few horsepower to 50,000-hp. units. The serious construction involved in the application to hydroelectric power, began in the early 90's, but at that time its use was still restricted by the limitation of transmission. In 1897, the highest voltage of transmission was 20,000; in 1900 this had grown to 40,000; in 1903, to 60,000; in 1908 to 100,000; in 1913 to 150,000; and today there are two lines being built in California whose operating voltage will be 220,000. One of these lines is approximately 250 miles long, the other something more than 300 miles.

The increase in voltage has made available many hydroelectric developments which in former years were too far from the center of application for the power to be transmitted, since the location of hydroelectric possibilities are not usually in sections which lend themselves to a large growth of population.

As the use of electric power became more and more general, and was not confined merely to lighting, the improvement and increase in size of generators became rapid, and the ease with which electric current could be applied to lighting and power purposes, made its application imperative throughout a very wide field, at present embracing some 3000 distinct uses.

It has been said that the growth of any community—large or small—depends largely on two factors, transportation and available power. It is therefore of the greatest benefit to any community to do everything possible to promote power developments and to show its public utility companies the greatest consideration.

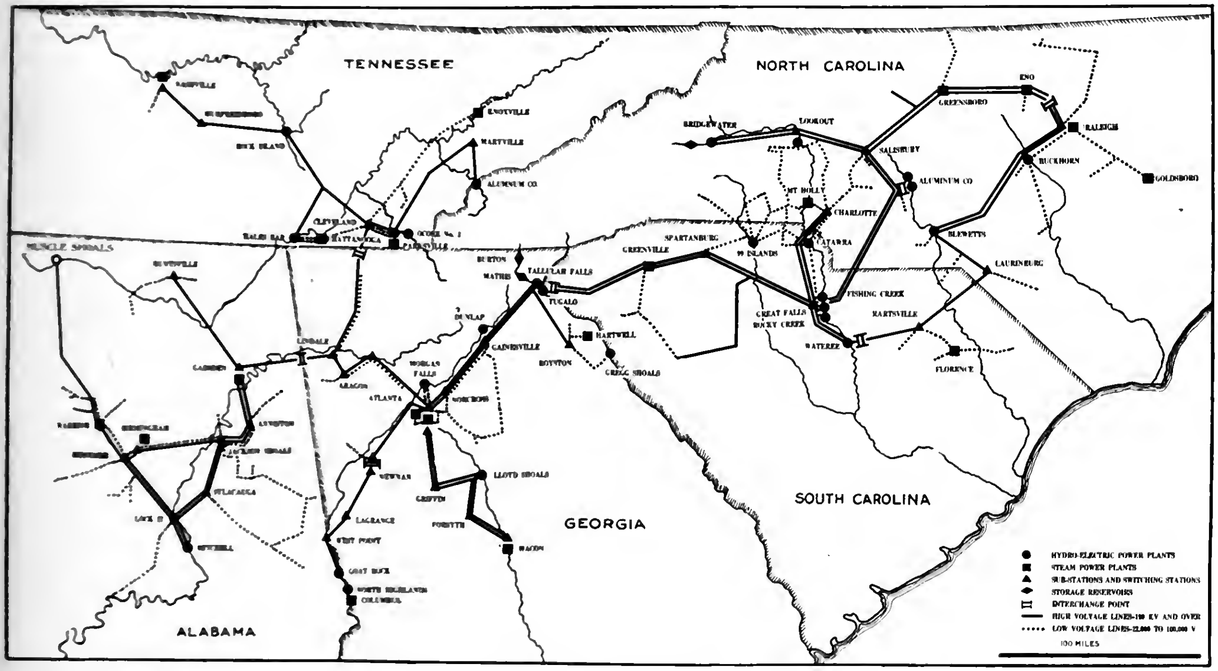

Fig. 1 Five-State Transmission System

Power Resources of the Southeast

The southeastern section is traversed by the great Appalachian Mountain Range, which rises to an altitude of from one to seven thousand feet above sea level, and enjoys an average annual precipitation greater than that of any section of the United States, the average ranging from 50 in. to 85 in. per annum. In the foothills of this mountain range are many streams and rivers which have a fall, as a rule, too great for them to be navigable and so lend

---

[1] Director and Executive Engineer, Georgia Railway & Power Co.

For presentation at the Spring Meeting, Atlanta, Ga., May 8 to 11, 1922, of The American Society of Mechanical Engineers. Copies may be obtained gratis upon request. All papers are subject to revision.

themselves admirably to economical development. This region also enjoys a climate of even temperature not subject to severe winters or ice conditions. The mean annual temperature varies from 55 deg. at an elevation of 2000 ft. above sea level to about 60 deg. at 500 ft. elevation.

The region is somewhat heavily timbered, especially on the head waters of the streams, and this to a large extent prevents a sudden run-off or great floods except during periods of extraordinary precipitation.

Five-State Development

It is intended to deal herein largely with the water-power and steam-generating stations that are now connected to the transmission system covering the five states of Alabama, Tennessee, Georgia, and North and South Carolina. The transmission system as shown in the accompanying map, Fig. 1, includes the five states mentioned, forming a trunk line some 900 miles long with several thousand miles of main line connected. It is operated at 110,000 volts, 3-phase, and at 60-cycle frequency. All of the large water-power and steam-generating stations in this territory are connected to this transmission system, making it possible to transfer power from one locality to another. This relieves power shortages due to periods of drought at water-power stations, or shortage of coal at steam plants or any other unforeseen circumstances which may interfere with the power supply in the different sections. In several instances, every power station connected to this system has been operated in parallel at the same time and with marked success. During the month of October, 1921, a part of Georgia and a part of North Carolina suffered a severe shortage in water due largely to the fact that the precipitation for the preceding six months was considerably below normal, but by means of the existing transmission system, both the affected areas were fully supplied with power from other parts of the system. Had this great transmission system not been in service, and interconnected, the industrial load in these two localities would have been necessarily dropped, since the power companies could not have supplied a larger amount of power than that required by the municipalities which they also serve. However, the other power companies by lending their assistance prevented any shutdown whatsoever in the industrial plants and the consequent unemployment of many thousand operators.

The table under Fig. 2 gives the installed capacity of the various power developments which are connected to the system under discussion. From this table it will be noted that the total installed capacity is 1,010,355 hp. The total output of the system during 1921 was approximately two billion kilowatt-hours.

New developments are constantly being made by the various power companies comprising this system, and there is now under construction an additional 310,000 hp. capacity in generating equipment. This does not include 90,000 hp. which will also be installed as an addition to one of the new plants at a later date, nor the much-discussed Muscle Shoals hydroelectric development, mention of which will be made later.

Water-Power Reserves

The steam generating stations of the Southeast, generally speaking, are used for the purpose of supplementing the water-power production. Many of the water-power plants are, however, also backed by large storage reservoirs, making their annual output practically continuous regardless of dry months or dry years. On the head waters of the Catawba River, the Southern Power Company has constructed a very large storage reservoir at Bridgewater, N. C., which has a capacity of 13,500,000,000 cu. ft., representing 90,000,000 kw-hr. under present conditions at the various water-power plants already constructed below. The Georgia Railway & Power Company has two storage reservoirs on the Tallulah River, one at Burton containing 5,280,000,000 cu. ft. and one at Mathis containing 1,369,000,000 cu. ft. This total storage on the Tallulah River represents approximately 70,000,000 kw-hr. at the present developments and makes available for use in power production at the plants below, about 95 per cent of the annual stream flow. This storage will later be equivalent to 125,000,000 kw-hr., when other developments contemplated and under construction are completed.

The diagrams given in Fig. 2 show the scheme for the complete development of the Tallulah River with reservoirs and power plants. These developments when completed will have an average annual output of 535,000,000 kw-hr., the reservoir capacity falling through 1220 ft. head. In this section the average annual precipitation is about 65 in., and the average annual run-off about 40 in.

The entire section of the Southeast is fortunate in having water power available which can be depended upon so completely due to the fact that great droughts seldom occur. There is no section of the United States with the exception of that adjacent to Niagara Falls, or in sections where the streams are fed from perpetual snows, where the flow of the streams and rivers can be so thoroughly depended upon. This insures a continuous supply of power to the various industries located in this section, with very little secondary power available or desired.

It may be interesting in passing to note that the power connected to the transmission system under discussion represents 17.75 per cent of the total water-power development in the United States.

Undeveloped Resources

While the Southeast has enjoyed extensive hydroelectric development already, it still has many sources of potential water power available for development as rapidly as the demand for electric power increases, and it will be many years before the entire possibilities of the streams in this section are exhausted. There are many industries not supplied at present with hydroelectric power which are depending upon the cheapness of fuel in the section where they are operating, and which in time will turn to electrical energy for their power needs. The electrification of the railroads of the South, which cannot be put off for many more years, will also provide an outlet for a large block of electric power, many of the trunk trail lines being already paralleled by transmission lines of sufficient capacity to meet their requirements.

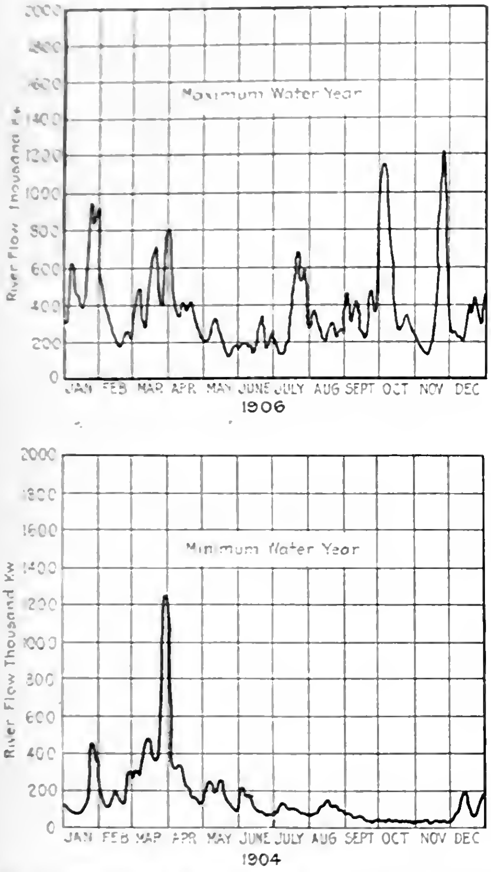

Fig. 3 Hydrographs of the Tennessee River at Florence, Ala., for 1904 and 1906

It has been found in communities where electric power is available and generally used, that the consumption amounts to approximately 500 kw-hr. per inhabitant per annum. As stated above, the total output per year of the various power companies connected to the system under discussion now amounts to 2,000,000,000 kw-hr. while the population of the territory served by this system is approximately 11,819,585, showing that there is only 34 per cent saturation in this territory, based on the consumption of electric power in communities where it is in more general use.

Muscle Shoals Conditions

Anything that is said or written about the power developments in the Southeast cannot pass without some reference to the Muscle Shoals hydroelectric development, especially that part of this development known as the Wilson Dam or Dam No. 2.

The Muscle Shoals section of the Tennessee River is the name applied to the fifty-mile stretch between the railroad bridge south of Florence, Ala., and Brown's Island, near Decatur, Ala., which is not now navigable during periods of low water comprising approximately six months of each year. The Shoals are located approximately 150 miles southwest of Chattanooga, Tenn., and are about 125 miles northwest of Birmingham, and a similar distance from Memphis, Tenn. They are about 200 miles in an air line from Atlanta.

Sometime prior to 1890 the effort of various individuals and organizations to do something with Muscle Shoals was begun, and the matter has been more or less active ever since that time. Every effort until recently has been in the nature of forcing the Federal Government to develop Muscle Shoals for the ostensible purpose of improving the navigation of the Tennessee River, with which very little navigation has ever existed, with the secondary object of producing hydroelectric power.

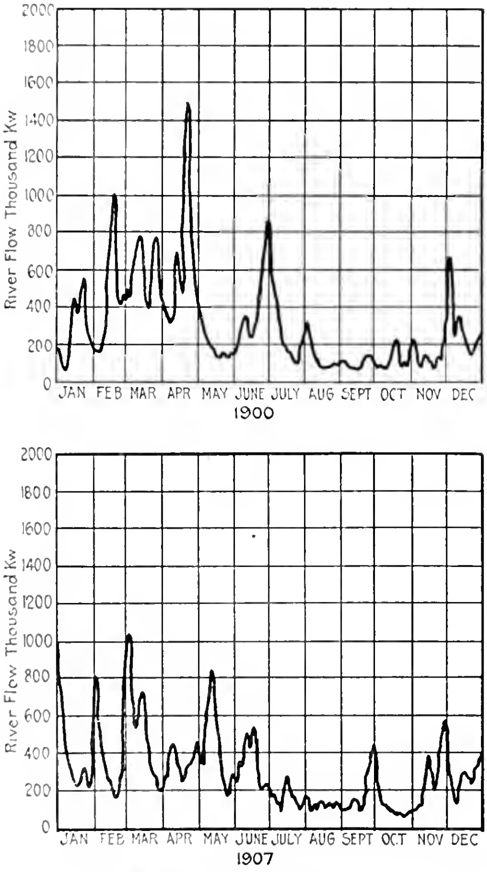

Fig. 4 Hydrographs of the Tennessee River at Florence, Ala., for 1900 and 1907

In the year 1890 a canal was cut around the Shoals by the Federal Government for the purpose of improving the navigation at this point, and this constituted the first step in the Government's activities at this location. Since that time, various bills have been introduced in Congress for the continued improvement of the river, but all plans have carried with them the idea of developing the hydroelectric power.

As soon as it became apparent that the United States would be ultimately drawn into the European war, it was brought to the attention of the Government that an interference with the supply of Chilean nitrates (sodium nitrate, $NaNO_3$) would seriously cripple the ability of the United States to supply ammunition for itself and associated nations in the war. So a clause was inserted in the National Defense Act of 1917, which appropriated twenty million dollars for the purpose of investigating the advisability of, and taking the necessary preliminary steps toward, the erection of a plant for the fixation of atmospheric nitrogen, the idea being that such a plant should be erected at or near some water-power site, remote from the sea coast, where the large amount of electric power required by the process would be cheaply available. The authority for this investigation and action was vested in the President, and he in turn selected a committee to carry out the intention of the Act.

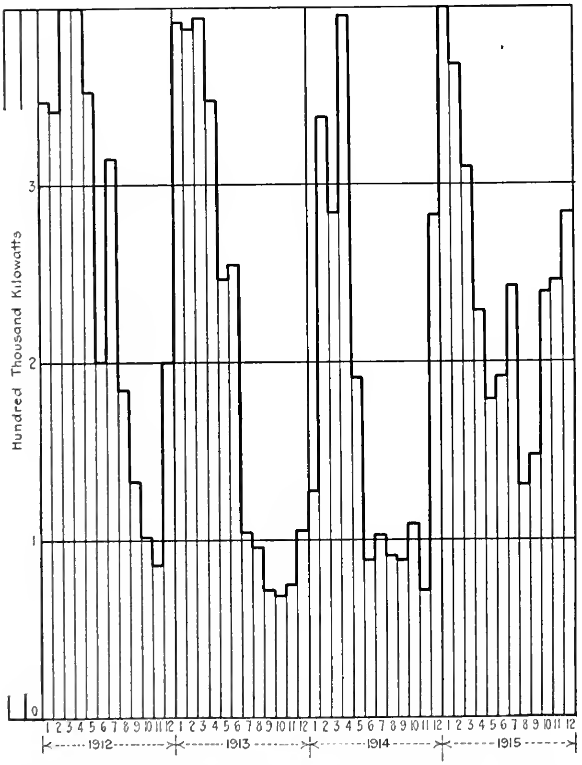

Fig. 5 Powergraph of Tennessee River from 1912 to 1915

Present Development

An early investigation of the water-power situation at Muscle Shoals indicated that the hydroelectric power plant could not be built in time for service during the war in connection with the nitrate plant, and as a consequence a steam plant was constructed at Nitrate Plant No. 2, with a capacity of 60,000 kw. in one three-part turbo-generator unit, room being provided in the plant for the later installation of a second unit of 30,000 kw. It is a modern, up-to-date plant, well designed and thoroughly efficient. The construction of this plant was carried out by the Government and cost approximately thirteen million dollars.

In addition, a steam unit of 30,000 kw. capacity was installed by the Government at the Warrior River steam plant of the Alabama Power Company, 90 miles from Sheffield, Ala., and connected with the nitrate plant by a 110,000-volt transmission line, the total cost of this improvement being approximately five million dollars. Also, a limestone quarry was purchased and opened at Waco, Ala., for the purpose of supplying the nitrate plant with the lime necessary in the production of calcium carbide.

To get back to the subject of the Muscle Shoals hydroelectric development: It was decided early in 1918 to call the dam the Wilson Dam, since the decision as to its construction was originally vested in President Wilson and it was he who directed that the project be carried out. At the time it was decided to proceed with the development, the property was more or less completely in the hands of the Muscle Shoals Hydroelectric Power Company. This company did not desire to stand in the way of any improvement which would further the prosecution of the war, and therefor surrendered all of its holdings, including dam sites, water right and plans to the Government for "one dollar and other considerations." As a consequence of these earlier negotiations, actual construction work on the project was begun during the spring of 1918.

The plans call for a dam about 100 ft. high and almost one mile in length, and include two locks for navigation requirements on the northern end of the dam with two 50-ft. lifts, said to be the highest-lift locks anywhere now contemplated. The dam is to be fitted with crest gates 18 ft. high for flood control, the gates to be counterweighted and operated by electric motors. The dam is to be of liberal gravity section, and will be constructed with a downstream apron which extends approximately 100 ft. below the toe of the dam, to protect the river bottom from the overfall. There is to be a highway bridge across the top of the dam above the gates. The dam will contain 1,250,000 cu. yd. of concrete. The power house is to be constructed on the southern end of the structure and built integral with the dam. It will contain a total of eighteen units, four of which have already been contracted for and built. They will be of the usual vertical type with 30,000-hp. water wheels, directly connected to 22,500-kw. generators, together with all the usual auxiliary equipment. It is now contemplated that the fourteen remaining units will be built with 36,000-hp. water wheels, and 27,500-kw. generators, making the total capacity of the plant in generating equipment approximately 400,000 kw. The power house is being constructed at this time for the full ultimate installation.

The Government has prosecuted this work somewhat intermittently since it was started, and has completed, up to the present time, a four-track bridge below the dam across the river for construction purposes, and the excavation for the power house. Two hundred and fifty thousand cubic yards of concrete have been laid in the dam structure on the north end, a portion of the excavation for the locks has been completed, and about 60 per cent of the excavation for the dam, of which there is a total of 620,000 cu. yd.

All of the work done on this project to date has cost approximately seventeen million dollars, and estimates covering the work necessary to complete the project vary from twenty to thirty-five million dollars. The work today is about 20 per cent complete and has been entirely shut down for more than a year.

Much has been said from time to time about the foundations at this dam site. A thorough investigation has been made by both diamond drills and well drills, and the records of these operations indicate that the foundations under the main part of the dam are satisfactory. There is, however, a seam appearing in the southern abutment which extends for a long distance into the surrounding country, and this is now being investigated by tunneling to see if it is or can be made watertight.

Possibilities

Volumes have been written in the Government records and in the press regarding the hydroelectric-power possibilities of Muscle Shoals. It is distinctly a run-of-river proposition, as no storage is created by the dam except that required to control the daily flow of the river. The Government at the present time has a requirement in existence for the benefit of navigation below, which will not allow the control of river flow under 10,000 cu. ft. per sec.

Boiler-Room Performance and Practice of the Colfax Station, Duquesne Light Company

By C. W. E. Clarke,[1] New York, N. Y.

IT IS the purpose of this paper to describe in some detail the operation of the boiler plant in the Colfax Station of the Duquesne Light Co., located at Cheswick, Pa. Fig. 1 is a cross-section of the boiler house and part of the turbine room of this plant. The Colfax Station at present contains one three-element-compound Westinghouse turbine of 60,000 kw. capacity and an additional similar machine will be installed this summer. The present plans for this station contemplate an ultimate capacity of 360,000 kw. The boiler plant contains seven boilers, 18 tubes high by 51 wide, each containing 20,867 sq. ft. of heating surface; and four additional boilers, 20 tubes high by 51 wide, each containing 22,914 sq. ft. of heating surface, are being installed this summer. The station is designed for base-load operation. Under present conditions it is possible to maintain a load in excess of 50,000 kw. for most of the day. For the night periods, from about midnight until seven or eight in the morning, the load may fall as low as 30,000 kw.

The boiler room was designed with a view to securing the highest ultimate efficiency in point of fuel, labor and fixed charges. It will be noted that the labor per horsepower is very small. The area covered by the boiler house per boiler horsepower is only 1.37 sq. ft.

Fuel and Fuel Handling

Coal is brought to the station on a standard-gage railway in 50-ton hopper-bottom cars from the Harwick Mine, which is owned by the Duquesne Light Company and located about a mile and a half from the power station. A space about 1000 by 400 ft. just north of the power station is provided for coal storage and is large enough for the storing of about 150,000 tons of coal. A rope-operated gantry bridge is now being erected for handling coal into and out of this storage.

At the plant, coal is dumped into receiving hoppers under the tracks. Crushers are located below the hoppers and the crushed coal is raised by two pivoted bucket elevators to distributing belt conveyors over the bunkers. As the coal goes to the crushers, water is added to help keep down the dust, and as an aid to combustion.

A representative sample of each day's coal is secured by taking individual samples of about 75 lb. from each carload as the cars are dumped. These are placed in airtight cans and so kept until they are to be used. The whole day's samples are then run through an automatic crushing and sampling machine which extracts a 3 to 4 per cent sample, amounting at the present time to about 40 lb. This 40-lb. sample is quartered on a clean floor and two 3-lb. samples are taken out and put in sealed containers. One of these is sent to the laboratory for analysis and the other is held at the plant until satisfactory analysis of the laboratory sample has been completed.

To secure samples of the coal as fired, a sample of about 1000 lb. is also taken from the stoker hoppers at 7 a.m. daily. This sample is treated in the manner described above. Table 1 shows the average of a number of proximate analyses of the fuel and Table 2 a representative ultimate analysis.

The coal bunker is of reinforced concrete and has a capacity of about 240 tons per boiler. Coal is not permitted to remain in the bunker longer than about three days, which practically eliminates any possibility of spontaneous combustion in the bunkers. Distribution of the fuel to the individual stoker hoppers is by means of two weighing larries each having a capacity of 10 tons. A number of openings in the bottom of the bunker are provided with short cast-iron spouts equipped with chain-operated gates and permit coal to be taken from any part of the bunker.

Stokers and Clinker Grinders

Each stoker is provided with an extension hopper, the capacity of the grate and hopper together being about 25,000 lb. The stokers are of the Westinghouse underfeed type and have 17 retorts of 20 tuyeres each. The projected grate area of each stoker is approximately 403 sq. ft.

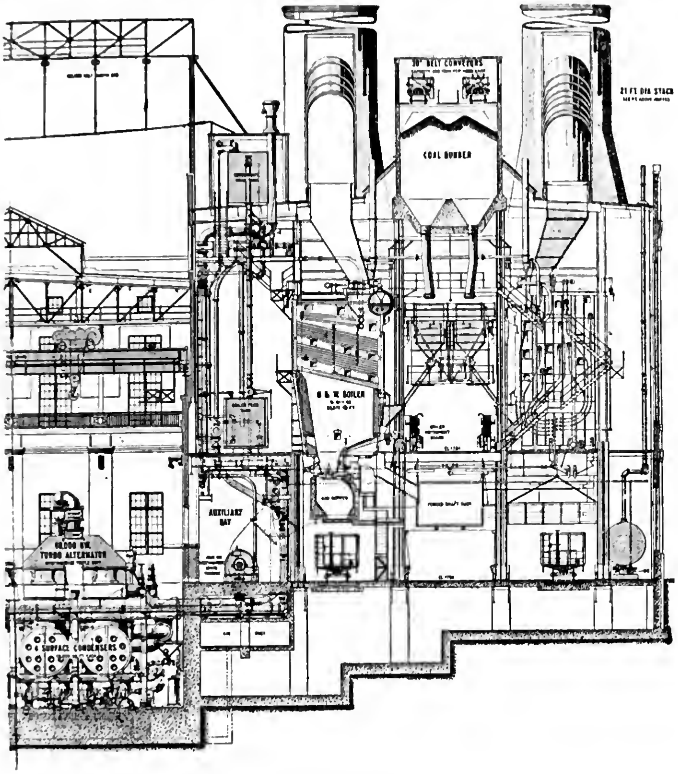

Fig. 1 Cross-Section of Boiler House and Part of Turbine Room

TABLE 1 PROXIMATE COAL ANALYSES

	As Received		Moisture-Free	
	As Unloaded	As Fired	As Unloaded	As Fired
No. of samples	25	30	25	30
Moisture, per cent	2.9	4.1	...	...
Volatile matter, per cent	34.5	34.1	35.5	35.6
Fixed carbon, per cent	53.0	52.5	54.6	54.8
Ash, per cent	9.6	9.3	9.9	9.6
Total, per cent	100.0	100.0	100.0	100.0
Sulphur, per cent	1.0	1.1	1.1	1.2
Calorific value, B.t.u. per lb.	13,351	13,237	13,758	13,895

The difference in moisture between the coal as unloaded and as fired is due to the addition of water at the crushers mentioned above.

TABLE 2 REPRESENTATIVE ULTIMATE ANALYSIS OF FUEL

	As Received	Dry Coal	Moisture-and Ash-Free
Ash, per cent	8.88	9.30	.....
Sulphur, per cent	1.09	1.14	1.26
Carbon, per cent	72.92	76.40	84.23
Hydrogen, per cent	5.39	5.12	5.64

B.t.u. per lb. by analysis	13,199	13,828	15,246

---

[1] Dwight P. Robinson & Co. Mem. Am.Soc.M.E.

Abstract of a paper to be presented at the Spring Meeting, Atlanta, Ga., May 8 to 11, 1922, of The American Society of Mechanical Engineers, 29 West 39th Street, New York. All papers are subject to revision.

Each stoker is driven by a 15-hp. variable-speed direct-current motor, equipped with both armature and field control. Current for these motors and for the clinker-grinder motors is supplied by two 2200-kw. 440-volt a.c. to 125-volt d.c. motor-generator sets located in the auxiliary bay of the turbine room.

The stoker operator is guided entirely by observation of the fires and of the wind-box pressure. The forced-draft-fan speed and consequent wind-box pressure are automatically controlled by variations of the steam pressure in the main header. Wind-box pressure is for this reason somewhat of an indication of load condition. The pressure over the fire is maintained at from 0 to minus 0.1 in. of water by means of balanced-draft damper controllers.

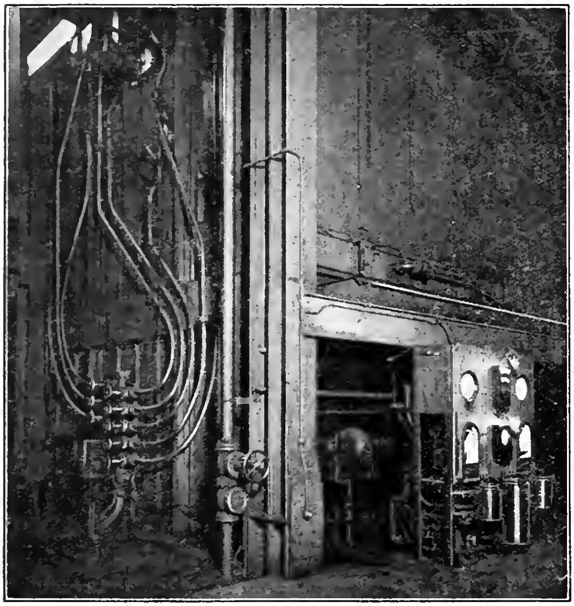

Fig. 2 General View of Boiler

In this type of stoker the upper and lower rams are linked together, but the movement of the lower rams is made much less than that of the upper through lost motion in the linkage. In case the fire piles up on the lower end of the grate this lost motion may be taken out by means of U-links which are left on until the fire is in proper condition. The stoker drive is capable of very close speed regulation and with ordinary care and the occasional use of the U-links, an even fuel bed suitable to the load may be maintained.

Each boiler is provided with an individual instrument and control board shown at the right in Fig. 2. At the top are two pressure gages connected to either end of the boiler drum. Between them is a three-in-one draft gage which indicates the pressure in the wind box, over the fire, and in the boiler uptake. Below the draft gage is a combined CO_2 and furnace-pressure recorder. Each of the two boiler-feed lines is provided with a Simplex venturi meter, the recorders for which are at the bottoms of the two side panels. Each of these meters has a capacity sufficient to feed the boiler at over 250 per cent of rating. The stoker and clinker-grinder motor controllers are bolted to the frame below the board, with the stoker-motor controller in the center and the clinker-grinder controllers at either side. This places practically the entire control for each boiler at one point so that but one stoker operator is required for 4175 nominal boiler horsepower, which is over 9000 developed boiler horsepower at 220 per cent rating, the normal daytime condition. No centralized control is provided as such a system is of doubtful advantage. The management of stokers, aside from that which can be made automatic, must be almost entirely through visual observation of the fuel bed. There are few factors of stoker control that can be centralized in such a way as to save either labor or fuel. Fig. 2 shows the general arrangement of the boiler, gage board, etc.

When this installation was first put in operation some difficulty was encountered with clinkering. After considerable experimenting it was definitely determined that this was due in part to periods when there was pressure over the fires and in part to improper water distribution in the clinker pits. Particular care is now taken to maintain a furnace pressure below atmosphere at all times, and the water distribution has been improved as described below with the result that clinker trouble has been practically eliminated.

Some trouble was at first experienced due to burning out of the lower front-feed wedges. This trouble has been largely eliminated by allowing air to blow through from the wind box, thus keeping the wedges cool. To facilitate replacement, the air-box tops and grinder-pit aprons have been made sectional instead of as in the original design.

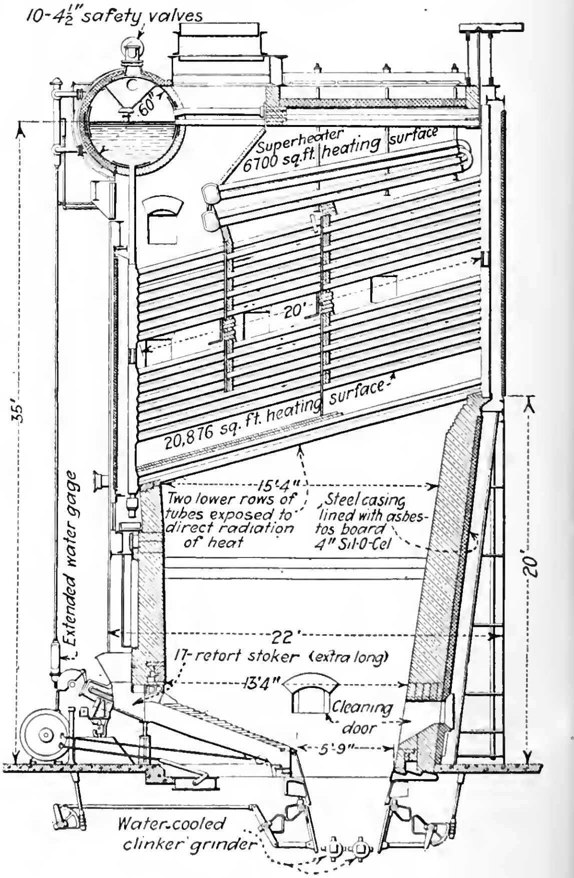

Fig. 3 Cross-Section of Boiler and Setting

The stokers are provided with double-roll clinker grinders, divided in the center, with the rolls turning toward each other. The two halves are driven by separate motors, separately regulated, giving individual control over the two halves of the grinder. The rolls are driven through reciprocating pawls and ratchets which may be disengaged on either roll. It has not been found desirable to operate the rolls continuously. Under normal operating conditions the rear rolls are operated rarely, the front rolls being run for periods of from two to five minutes in every twenty minutes, which means from six to eight revolutions in one hour. Grinder operation is governed entirely by observation of the ashpit. The top of the ash bed is kept above the top of the rear wall air boxes.

To prevent the formation of clinker masses in the ashpit and to cool the clinker rolls, water is introduced above the rolls. Upper-grate box tops having a down-turned projecting lip are installed,

under which lip is placed a horizontal spray pipe perforated with quarter-inch holes six inches apart. This pipe introduces the water high up in the ashpit and quite effectually prevents the formation of hard clinker masses. The introduction of water high up in the ashpit tends to quench the ash before combustion is as complete as could be desired, thus increasing the amount of combustible in the ash. At the present time this seems to be the lesser of two evils. The sprinkling system requires about fifty gallons per minute for each boiler.

Ash Handling and Sampling

The clinker grinders discharge into firebrick-lined reinforced-concrete ash hoppers with an approximate capacity of 60 cu. yd. These hoppers will hold the refuse of from one and a half to two days' normal operation. It is the regular practice, however, to remove the refuse from all working boilers twice a day.

A sample of ash from each boiler is taken every other day. A gross quantity of about 400 lb. is taken from the total 24-hr. dump from each boiler, the sample being taken from six different points in the pile, at a depth of about three feet below the surface of the pile. The whole sample is then hand-crushed and quartered until about three pounds remain, which is sealed in a container and sent to the laboratory to be analyzed for combustible. The method of analysis is in accordance with the specifications of the American Society for Testing Materials.

Boilers

There are at present seven boilers of the Babcock & Wilcox cross-drum type, 18 tubes high by 51 wide, with 20,876 sq. ft. of heating surface and with the so-called "Alert" baffling. There are 918 tubes in each boiler proper and 102 circulating tubes connecting the uptake headers with the drum, making 1020 tubes in all. Fig. 3 is a cross-section of the boiler and setting. It will be noted that the combustion space is large. The present settings contain 0.345 cu. ft. of combustion space per square foot of heating surface and those to be installed this summer will be the same.

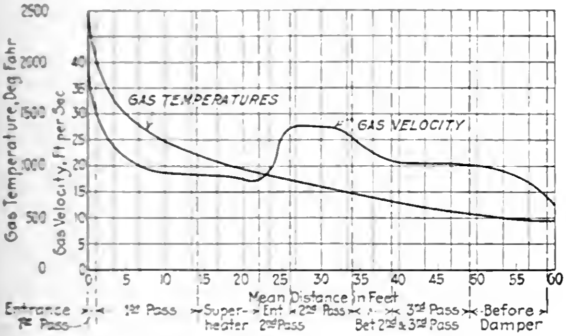

Fig. 4 Variation of Temperature and Velocity of Flue Gas Throughout the Boiler

Each boiler has two water columns with high- and low-water alarm whistles. When one of these alarms sounds the operator examines the feed regulators for possible sticking, and if necessary cuts it out and uses hand control until repairs can be made. If the regulator is found to be all right he checks up the feed pressure and if necessary starts another pump or puts on the auxiliary feed.

Furnace temperatures vary from 2500 to 2800 deg. fahr.; at the top of the first pass this approximates 1000 deg. fahr., between the second and third passes it is 530 deg. fahr., and the exit gas temperature varies from 450 to 480, usually being about 470 deg. fahr. Fig. 4 is a chart showing the temperature range and gas velocities through the boiler. Typical temperature and CO_2 traverses are given in tabular form in the complete paper.

Slagging on the boiler tubes is slight and has never been sufficient to cause trouble. The use of distilled make-up water eliminates trouble from scale and consequent tube renewals. The total commercial operation of the seven boilers now installed has been approximately 39,922 boiler-hours up to February 1, an average of 5703 hr. per boiler and but two tubes have been replaced.

Each boiler is equipped with eighteen soot-blower elements, nine on each side. These soot blowers are operated three times a day with the dampers opened wide.

In the past boilers have been taken off for cleaning and repairs after 30 to 45 days of service, but it is expected that in the future service periods will be from 90 to 100 days. This increase is due to some slight modification of the settings and increased knowledge of the performance of the equipment. The work of inspection and repair ordinarily takes from 10 to 11 days. Full efficiency is not reached until from four to seven days after the boiler is put on the line.

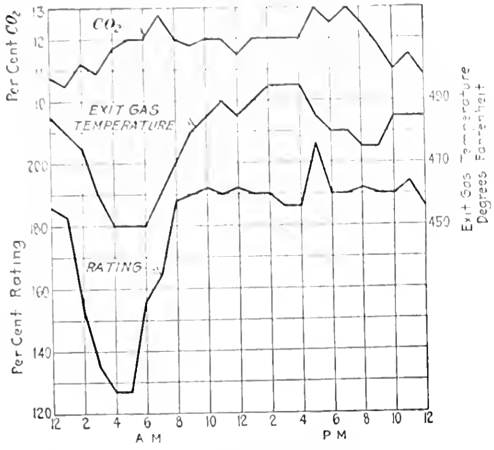

Fig. 5 Hourly Variation in Rating, Gas Temperature and CO_2 for Typical 24-Hr. Day

The settings are of firebrick throughout, the brick walls being 18 in. thick. Sil-O-Cel and asbestos millboard fill the $4^1/_4$-in. space between the firebrick and the steel casing. Deterioration of the setting is very slight.

The formation of clinker on the furnace walls is prevented by air cooling, Bernitz and Drake blocks being used. These blocks did not altogether prevent clinkering on the side walls and side-wall tuyeres have been installed, which have practically eliminated it.

The superheaters are located over the tube banks between the first and second pass. Considerable trouble has been experienced because of insufficient superheat. The normal superheat should be 180 deg., but 145 deg. has seldom been exceeded. The boilers to be installed this summer will have the superheaters located above the sixth row of tubes, and with this arrangement no trouble from deficient superheat is anticipated.

There is one forced-draft fan for every four boilers. The fans are of the radial-flow type, and have a capacity of 250,000 cu. ft. of free air per minute at a maximum static pressure of 6 in. of water. The fans are driven through reduction gears by 420-hp. turbines. Each fan turbine is provided with a speed controller actuated by variations of steam pressure in the main header. Ordinarily no control of the stoker air other than that provided by the automatic, forced-draft-fan speed control is used, although individual wind-box dampers are provided that may be used in case of emergency. There is one main forced-draft duct, 9 ft. 6 in. by 15 ft., running beneath the firing-aisle floor, from which all stokers are supplied. This duct is provided with sectionalizing dampers located midway between the fan inlets. At each boiler a branch duct runs from the main duct to the stoker wind boxes. The duct system is of $^3/_{16}$-in. sheet steel made practically airtight without welding.

The generator-cooling-air discharge is carried to the main air-supply duct from which the fans take part of their supply. In addition to this, large openings are provided at the tops of the fan chambers through which air may be drawn from the top of the auxiliary bay. In winter the openings between the fan chambers and the boiler-room basement are closed. This is done to prevent freezing of piping due to drawing large quantities of air from outdoors through the boiler-room basement.

Fig. 5 shows the hourly variation in boiler-room operation over a typical 24-hr. period. Fig. 6 shows the average efficiency, rating and gas temperature for all boilers for the period from July, 1921 to February, 1922. This clearly shows the steady increase in efficiency as conditions were improved and as the operating force became more familiar with the equipment. The low point at the beginning of December was due to a period during which there was considerable trouble with clinker.

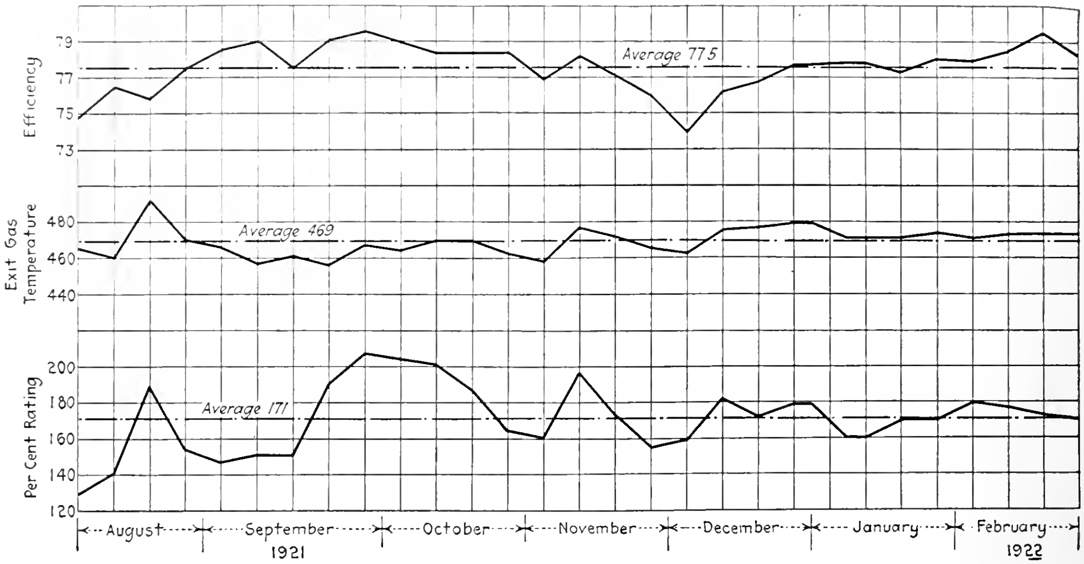

Fig. 6 Average Weekly Boiler Performance for All Boilers

Note—The points on this curve are the weighted averages of the average weekly efficiencies for the individual boilers, hence the variations at some points.

Piping System

The piping system for boiler feeding consists of a main and auxiliary header. The main header runs below the firing-aisle floor and between it and the forced-draft duct. A feed line is carried up each side of the boiler (these boilers are provided with feed connections at both ends of the drums) and is controlled by globe valves at the boiler-room floor level. Automatic boiler-feed regulators are provided on the feed lines at the boiler drums, part being Stets and part Copes regulators. The auxiliary header runs over and at the rear of the boilers. The auxiliary feed line on one side of each boiler is provided with a by-pass through the automatic controller, that on the other side being provided with hand control only. The boiler-feed system in general is described below.

The piping system was installed in accordance with the general piping specification given in the complete paper.

Feedwater System

The feedwater cycle is shown diagrammatically in Fig. 7. All water in the system is distilled. Make-up water is provided by two evaporators of the double-effect, dry-tube type. Water from the evaporators is pumped directly to the head tanks, above the barometric condensers, which serve as feedwater heaters. The average make-up required is about 1.9 per cent of the total amount flowing in the system. The tail pipe of the barometric condenser is sealed in the boiler-feed tank from which the feed pumps take their suction. Two V-notch meters are provided in this tank; one measures the water going to the feed pump and the other the overflow. All overflow from the system is piped to the boiler-feed tank so that it is recorded by this meter. Overflow from the boiler-feed tank flows to the main storage tank mentioned below. There is some variation between the water quantities recorded by the venturi and V-notch meters, but it is the venturi-meter readings which have been used as a basis for all results given in this paper.

There are three 4-stage 1500-g.p.m. turbine-driven centrifugal boiler-feed pumps, regulated to maintain a pressure in the feed system of 350 lb. per sq. in. One pump is sufficient to supply the total feedwater for a load of about 60,000 kw.

Condensate from the main unit goes first to a surface heater where its temperature is raised about 4.5 deg. fahr. by the transformer- and turbine-oil cooling water. It then goes to the evaporator condenser serving there as a circulating medium, and its temperature is increased about 32 deg. fahr. From the evaporator condenser it goes to the head tank and then through the barometric condenser. The exhaust from the house turbine and that part of the exhaust from the auxiliaries which is not used in the evapora-

tors is here condensed, bringing the temperature of the mixture to about 205 deg. fahr.

The storage tank employed has a capacity of 200,000 gal. and serves to take up fluctuations in the demand for feedwater and to provide a reserve supply for emergencies.

The evaporators have in general given satisfactory service. They are so connected that either river or deep-well water may be used. The river water, although very dirty, was found to contain less scale-forming salts than that from the wells, and is therefore generally used. The effects are reversed every four hours, thus minimizing scale formation. The thermal efficiency of the evaporators is practically 100 per cent, and with the modifications now being made it is thought they will give no trouble.

Water qualities throughout the cycle are closely watched. A multiple-point, indicating conductivity meter with cells located at various points is used to observe the water purity continuously. This instrument immediately indicates leakage of circulating water into the condenser and permits a close check in the quality of the distillate from the evaporators. No condenser leakage has as yet been detected, but much useful information on the performance of the evaporators has been obtained.

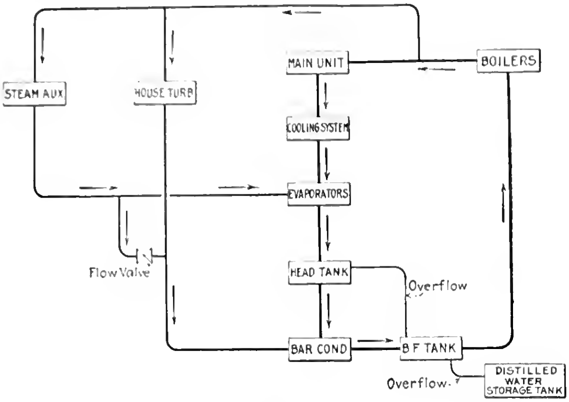

Fig. 7 Diagram of Steam and Feedwater Cycle

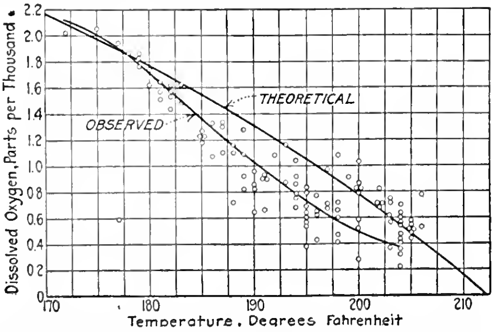

Fig. 8 Comparison of Actual Dissolved Oxygen in Colfax Boiler Feedwater with Theoretical Solubility at Varying Temperatures.

It has been found that dissolved oxygen in the feedwater tends to pit the boiler drums. It has also been determined that this pitting takes place during banked periods, there being practically

none when the boiler is active. In order to decrease the quantity of dissolved oxygen to the lowest possible point, all parts of the feed cycle are effectually sealed against air. The feed temperature is maintained at 205 deg. or higher to drive out the entrained air. Further experiments are being carried on to determine whether a lower feed temperature with a higher vacuum in the barometric condenser will improve this condition.

Fig. 8 shows the relation between temperature and oxygen content as observed at Colfax. Table 3 gives the results of observations of dissolved oxygen in the boiler feedwater taken from the condensate-head tank and the boiler-feed tank.

Tables 4 and 5 show the personnel of the boiler-room organization with one unit as at present, and as it will be when a second unit is installed.

Table 6 is a summary of boiler-room operations for the month of December, and Table 7 a recapitulation for the six months, August to January, inclusive.

The heat balance for the station is worked out daily. Table 8 shows the averages of the heat-balance figures for the months of October to January, inclusive.

Conclusions

In considering the results given in the paper the following points should be borne in mind:

a The operating results given are from the records of the operating department of the Duquesne Light Company

b The plant is not equipped with heat-reclamation equipment such as economizers or air preheaters

c The efficiencies given are not test results but have been made with the regular operating force and can be maintained year after year. The results are good but do not represent the best performance possible with the equipment. Some further improvement is expected as the operating force becomes more familiar with the equipment

d The amount of combustible in the ash is high, but as explained above, the necessity for early quenching of the ash to prevent clinker makes improvement in this respect doubtful. In the light of over-all efficiency the slight excess in combustible is a lesser loss than the formation of hard clinker masses would occasion.

POWER DEVELOPMENT IN SOUTHEAST

(*Continued from page 294*)

The lowest stream flow ever recorded was 6900 sec-ft., which corresponds to a load of 43,125 kw. under the proposed plans for the development.

The greatest fluctuation in any stream in the Southeast probably occurs in the Tennessee River. The United States Government in planning a development at Muscle Shoals recognized this fact and contemplated an installation of 400,000 kw., only a portion of which can be depended upon for continuous power. According to the hydrographs of the river at this point, the amount of strictly primary power at Muscle Shoals averages about 100,000 hp., and even this figure is based on the assistance of some steam capacity which must be maintained. It is a source of considerable regret to engineers who are familiar with the Tennessee River to read in the press of the enormous amount of power allotted to Muscle Shoals development, usually stated as 1,000,000 hp., and the consequent misleading of the general public on this much discussed project. The development has distinctly a stream-flow characteristic, the discharge of the river varying widely from month to month, and more markedly from year to year. The contemplated capacity of 400,000 kw. at Muscle Shoals could be operated under full load only at widely separated intervals, since the river flow does not equal this amount of power except on an average of less than thirty consecutive days per year.

In Fig. 3 are shown hydrographs of the Tennessee River at Florence, Ala., for the year 1906, which is the maximum water year recorded, and for 1904, which is the minimum water year recorded. It will be noted from the curve for 1904 that for a large part of the year the flow at Dam No. 2 would have produced only approximately 50,000 kw., while in the maximum water year, for a large part of the time, the flow falls below 200,000 kw. In studying the hydrographs of this stream covering a period of approximately thirty years, the years 1900 and 1907 have been found to represent about the average conditions of river flow. The hydrographs for these two years are shown in Fig. 4, and it will be noted that the continuous output that can be depended upon throughout these average years is in the neighborhood of 100,000 kw.

In Fig. 5 is shown a powergraph of the river for four consecutive years, 1912, 1913, 1914, and 1915, which are typical years, based on an installation of 400,000 kw. capacity, as proposed by the United States Government at Dam Site No. 2. It will be noted that in each of these years except one the stream flow at some times falls below 100,000 kw., and that only at widely separated intervals does the stream flow equal or approach the 400,000-kw. mark. It can be seen from these hydrographs that the statement of one million horsepower which has appeared in the press repeatedly, is a gross exaggeration of the output to be expected from the plant at this location. There are many undeveloped water-power sites in the Southeast which can be developed on a commercial basis to much greater advantage than the development at Muscle Shoals.

From the foregoing it can be seen that the Southeast is open for great industrial development, as it either has or can develop the necessary hydroelectric power, and enjoys the natural advantage of an even and salubrious climate, together with a very large store of raw materials in both its agricultural and mineral resources.

Results of an investigation made by the U. S. Geological Survey in 1921 show that the total water power developed in the United States is now 7,852,948 hp., the figure representing the capacity of the water wheels installed in plants of 100 hp. or more. There are 3116 such plants; 79 per cent of their total capacity is in public-utility plants and 21 per cent in manufacturing plants. Undeveloped water-power resources are shown to be a minimum of 27,943,000 hp., based on low-flow data.

Modern Shop Practice in the Building of Revolving Flat Cards

Details of Special Machines Developed for the Work—Production Cost Per Unit Lowered by Efficient Shop Arrangement, Careful Machine Designing and Standardization

By F. E. BANFIELD, JR.,[1] NEWTON UPPER FALLS, MASS.

BEFORE taking up the details of manufacture of the modern revolving flat card, it may be of interest to trace briefly the development of this machine in order that one may better appreciate the extent to which the art of its manufacture has been developed.

The primitive method of carding or cleaning cotton fibers was by means of hand cards which consisted of brushes made of short pieces of wire instead of bristles, the wires being fastened into a sheet of leather at a certain angle, and the leather fastened into a flat piece of wood about twelve inches long by five inches wide and provided with a handle. The cotton was spread upon the surface of one of these cards and then combed with another until all the fibers were straight, after which it was stripped off in the form of a roll.

The first attempt to card by the rotary motion of a cylinder was covered by the English patent taken out by Lewis Paul in 1748, but it was not until 1790, when Samuel Slater, an Englishman who had settled in Pawtucket, R. I., built the first cards to be operated in this country that carding or cleaning cotton fibers by machine was introduced here.

In 1857 Evan Leigh produced a card embodying all previous developments and having the additional advantage of being equipped with a mechanical device to automatically strip the tops or flats. This type, known as the revolving flat card, was destined to come into almost universal use and is today the standard of the world for carding cotton fibers. Although many modifications and improvements in the construction of this machine have since been made, its fundamental features remain the same.

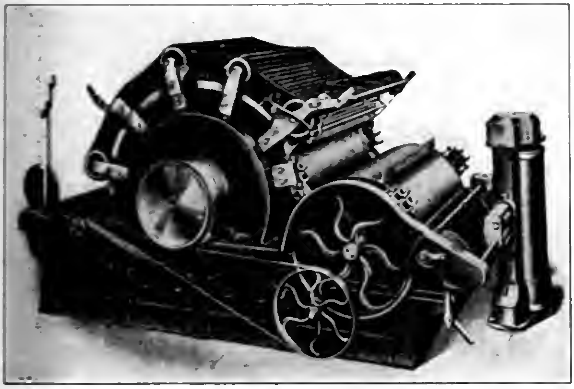

FIG. 1 MODERN REVOLVING FLAT CARD

In Fig. 1 is shown a revolving flat card as it is built today. While there are several different makes of these machines, varying somewhat in details of design, the essential features and characteristics are the same in all.

It was not until the year 1884–1885 that American manufacturers came to realize that the efficiency of this type of card was at least 100 per cent higher than the best of the wooden-top flat cards. As soon as this advantage was made apparent to mill owners the demand for these cards became large, and during the next decade English cards of this type were brought into this country by the shipload. It therefore became necessary for the American machine manufacturer to adopt this new design for his product in place of the old-style machine, in order to compete successfully with the English builders. He was not prepared to manufacture this radically different and highly developed machine. Many of its component parts were so designed that they were not readily adapted to machining on standard commercial types of tools. A start was made by purchasing from England such machines as were available, but it soon became apparent that it was up to the American manufacturer to devise and build special-purpose tools and equipment if he hoped to succeed against the English competitor.

It is the purpose of this paper to show some of the results of the efforts in this direction by describing some of the more important machines which have been developed for this work. In designing these machines the one object which has been constantly borne in mind has been that they must not only do the work cheaper, but it must be of better quality.

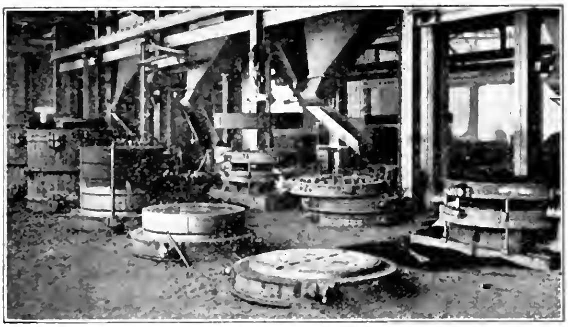

FIG. 2 CYLINDER MOLDING FLOOR

One of the first requisites for economic machine-shop production on a quantity basis is carefully molded uniform castings; otherwise satisfactory work cannot be obtained from the jigs and fixtures employed in holding the castings for the subsequent machining operations. For the average card casting with its more or less deep draws and flanges, the stripping-plate type of molding machine has been found best suited. An iron pattern once properly fitted to a stripping plate is good for almost a countless number of castings, and thus made their accuracy in no wise depends upon the skill of the molder. In fact, an ordinary laborer can in a few days be taught to make as good castings from a stripping-plate pattern as a skilled molder who has served his time in a foundry.

Developments in molding machines in recent years have made it even possible to adapt the cylinder and doffer patterns to stripping-plate machines and in Fig. 2 we have a view of the cylinder floor showing some of these machines and illustrating the method by which the molds are built up. This equipment consists of four jolt stripping-plate machines, the drag, the cope, the core and cheek, the first two being seen at the center and the right of the photograph. The molds are shown from the right to left in their successive stages of completion. To provide for the flanges on the inside surface of the cylinder, the core is built up in four sections, one of which is seen suspended from the overhead crane by which it is handled. Each section is built upon a cast-steel arbor which serves as a means for handling and also provides a support for the upper cores. After the cores are in place the cheek is lowered into posi-

[1] Superintendent, Saco-Lowell Shops. Mem. Am.Soc.M.E.

Abstract of paper for presentation at the Spring Meeting, Atlanta, Ga., May 8 to 11, 1922, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. All papers are subject to revision.

tion and the mold is then closed with the cope and ready for pouring. This is done through a central sprue passing down through the cores and thence through radial gates in the drag to the cylinder wall.

Fig. 3 is a view of the card-side floor showing the pattern mounted on a stripping-plate machine at the right. The drags are made from this machine while the copes are rammed up on the plate at the left. In the foreground may be seen two drags ready for the cores to be set. Over 70,000 molds have been made from this pattern and it is still in serviceable condition.

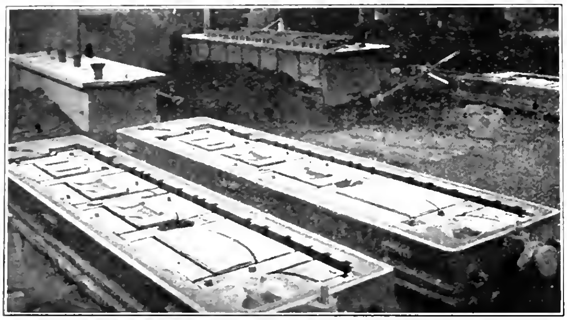

Fig. 3 Card-Side Molding Machines

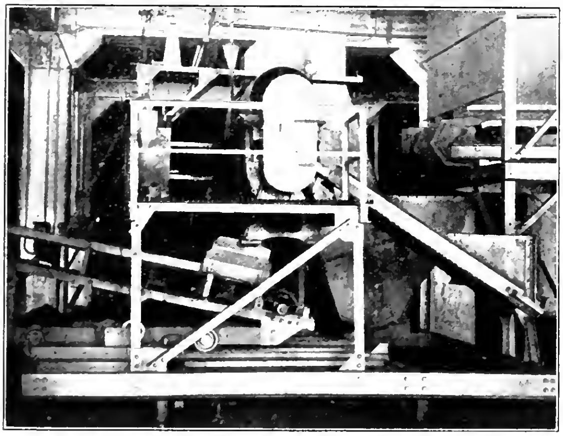

Fig. 4 Sand-Mixing Machine

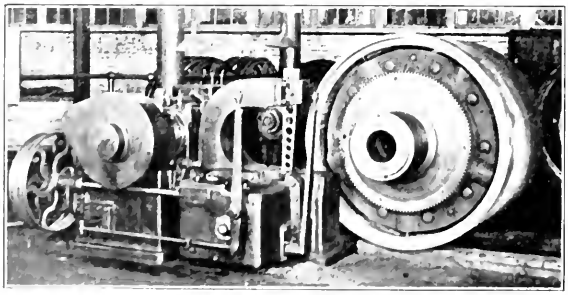

Fig. 5 Cylinder-End Milling Machine

After pouring, the molds are shaken out over gratings in the floor, through which the sand falls into hoppers located in the basement. Serving these hoppers is the sand-mixing machine or car, shown in Fig. 4. A hopper is located on the right from which a slow-moving feeder delivers the sand to the hopper of a bucket elevator mounted on the car. This elevates the sand to the mixing machine where it is riddled, tempered and mixed and then dropped on to a belt conveyor which delivers it to the bucket elevator at the left ready for the hopper over the molding floor above. This sand car is operated on a track, running the length of the foundry and so located that the car serves all of the hoppers in the bay in which it operates. This equipment does away with the laborious work of shoveling the sand and it also mixes and prepares it much more thoroughly than is possible by hand, thereby producing not only better but cheaper castings.

For transportation of materials, an electrically operated monorail system has been installed. Not only are the cars electrically driven but the switches are also operated in this manner, being controlled by a button in the operator's cab. Special cars are also arranged with ladles for carrying the molten iron from the cupola to the molding floors, and arranged so that the tilting of the ladle for pouring is done by the operator of the car. This system has aided materially in reducing the cost of transportation as well as increasing the capacity of the foundry by speeding up the work.

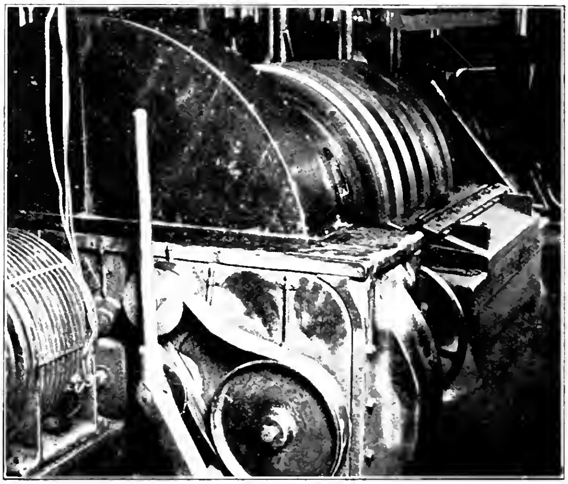

Fig. 6 Cylinder Roughing Lathe

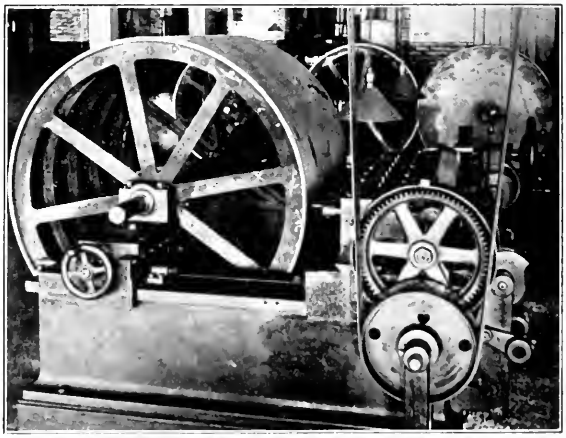

Fig. 7 Cylinder Drilling Machine

Machining of the Castings

Upon the solid construction, the true running and the perfect balance of the card cylinder, depends to a large degree the successful operation of the card. Its surface is covered with card clothing which in turn is set to run but a few thousandths of an inch away from the surfaces of the lickerin, the flats and the doffer, and it is

Fig. 8 Shaft Roughing Lathe

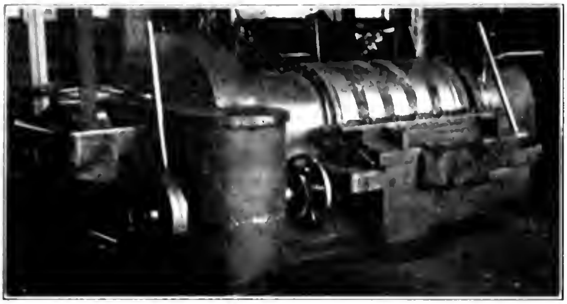

Fig. 9 Doffer Roughing Lathe

essential that this small clearance be accurately maintained as otherwise serious damage might result to the clothing. This cylinder has a diameter of 50 in., a length of 40 or 45 in. according to the width of the card, and runs at a normal speed of 165 turns per minute. It is the largest of the parts entering into the assembly of the card and its machining operations are such as require the use of several of the special single-purpose tools heretofore mentioned.

The first operation on the cylinder consists of squaring up and boring out the ends to receive the spiders. For a long time this was done on boring out lathes designed and built for this purpose in England, several of which were purchased and brought to this country.

Then in order to obtain an increased production and at the same time eliminate the possibility of inaccuracy, it was decided that a milling machine was the type best suited to produce these results. Accordingly the special machine shown in Fig. 5 was designed and built for this work. The cylinder is held on an expanding arbor or chuck, one end of which carries the feed gear corresponding to the rack of the ordinary milling-machine table. The cutters are mounted on the inner ends of two spindles, one on each side of the machine, these spindles, in turn, being driven by spur gears from a motor-driven cross-shaft at the rear. The spindles are mounted in quills so arranged that they may be fed into the ends of the cylinder to the desired depth after it has been rolled into place. A sliding-drive pinion is then moved into mesh with the feed gear on the chuck; this pinion being driven from the cross-shaft shown on the side of the machine. A tight and loose pulley on this shaft receives a belt from a pulley on the motor shaft, the feed being started and stopped by the shifting of this belt. The arbor on which the cylinder is mounted is held in position in the horizontal U-shaped bearings of the machine by means of the steel wedges shown. The photograph shows the cylinder ready to be rolled into position. The head carrying the cutter spindles is adjustable and when once set for a certain diameter of cutter, work of uniform dimensions is produced and is not dependent on the care of the operator, who merely loads and unloads the machine. This machine is capable of finishing one cylinder per hour, one-third the time required on the previous lathes.

When bored or milled out the cylinder is taken to the roughing lathe (Fig. 6) where it is held by the bored ends and a roughing cut is taken across its outer surface. To convey an idea of the size of this machine, it may be of interest to state that the head- and tail-stock spindles are both 30 in. in diameter, the former carrying a driving gear 6 ft. in diameter. The spindles are of cast iron and run in cast-iron bearings, which have shown no appreciable wear during ten years of continuous service. The tool block carries six tools spaced at equal intervals so that each tool travels but one-sixth of the length of the cylinder, the entire surface being finished by this movement.

A spider is then driven into each end of the cylinder where it is securely bolted and doweled in place. The holes are then line-reamed to receive the shaft, which is pressed into place in a heavy horizontal power press, 0.005 in. being allowed for the forced fit. As a further precaution, a $^5/_8$-in. dowel pin is driven through the hub of the spider and shaft at the driving end. This method of construction obviates any possibility of the shaft becoming loose from long-continued operation and insures a true-running cylinder.

It is then mounted on its own bearings in a special finishing lathe where a continuous chip is taken from one end to the other with a single tool, after which it is ready to be drilled for the wooden plugs which are driven into its surface and to which the clothing is tacked. This drilling operation is performed in the horizontal gang drilling machine shown in Fig. 7. The drills used here are of the flat type and so shaped as to drill and ream a tapered hole suitable for receiving the wooden plug.

After plugging, the cylinder is carefully ground on a special cylinder grinder. Operations on the spider, consisting of boring and reaming the hub, of turning the outside circumference to size and of facing one side of the rim, are done on a boring mill so equipped that all of these operations may be performed at one setting of the work.

Finishing the Shafts

The shafts used in the cylinders and doffers are of cast iron and each end is finished to three different diameters, one to fit the spider, one the bearing, and the third, or outer one, the pulley. For rough-turning these shafts the special machine shown in Fig. 8 was developed to turn both ends of the shaft at the same time. As

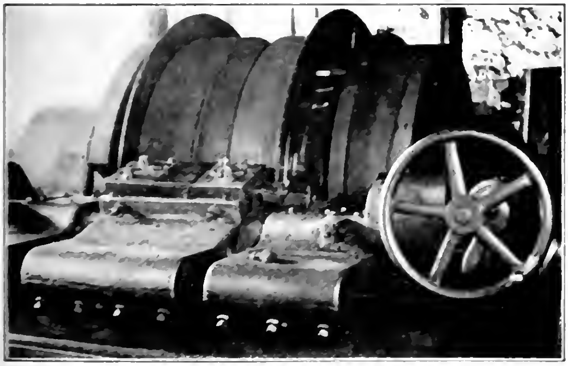

Fig. 10 Arch Milling

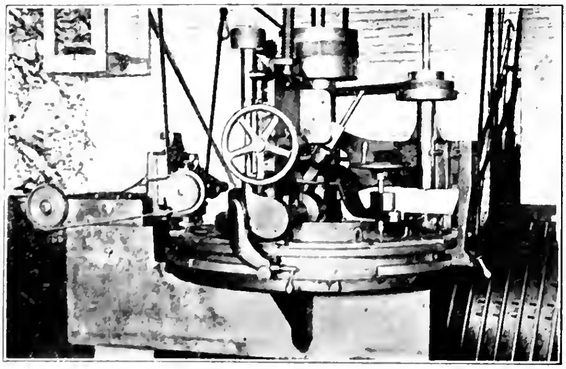

Fig. 11 Arch Milling, Drilling and Tapping

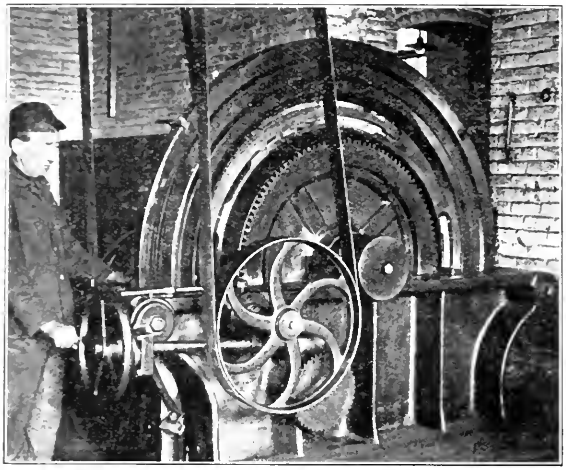

Fig. 12 Flexible-Bend Milling Machine

will be seen, the central head carries a hollow spindle driven by a gear on the main driving shaft at the rear of the machine. On each end of this hollow spindle is mounted a special concentric chuck for centering and gripping the casting to be turned. The tailstock spindles, one at each end of the machine, are arranged in horizontal turrets or drums which may be rotated in their respective heads and whose axes are located below that of the driving spindle. These turrets are also fitted with a rotating center drill, the driving gears of which are thrown into mesh as it is moved up into line with the axis of the shaft. The third position of the left-hand turret carries a stop which locates the work in the machine, while the corresponding position of the right-hand one is provided with an opening through which the work is passed into and out of the machine. Each carriage is provided with a front and back tool block, the former carrying two turning tools, while the latter carries a single inverted one. Thus, three tools are in operation at each end of the shaft, one for each of the three diameters.

The shaft then goes to a lathe equipped with two carriages, each of which is fitted with a tool block arranged with tools for squaring the shoulders to length. It is then ready for the grinder where both ends are carefully ground to size. After cutting the keyway for the driving pulley with a vertical end mill, the hole for the oil screw is drilled and tapped in the end and the shaft is completed, ready to be pressed into the cylinder.

The operations of finishing the doffer follow closely those of the cylinder, the rough-turning being done on the machine shown in Fig. 9, which greatly resembles the cylinder roughing lathe (Fig. 6). After the spider and shaft are in place, the doffer is drilled, ground, and balanced in a manner similar to the cylinder.

The sides and arches of the framework of the cards are finished by special machines since the successful manufacture of these parts requires close adherence to accuracy in order to insure interchangeability and to reduce to a minimum the fitting required in the erecting room. In order to secure a straight and even surface on which to erect the card and attain proper alignment of the bearings, the top surfaces of the sides are further finished on a special planer type of grinder carrying a vertically mounted motor-driven ring wheel.

The arch which is that portion of the frame carrying the stands which support the flats and their driving and adjusting mechanism as well as the sheet-iron casing below them, is by the nature of its design, the most awkward as well as one of the most important parts of the card to machine. The proper settings of the different parts require the accurate location of the various spottings on which the stands are mounted. The first operation after squaring off the bottom of the feet is the milling of the outer rim, this being done on the machine shown in Fig. 10. The rotating drum carries a pair of these arches, one right and one left hand. As this drum rotates slowly the circumference of the rim of the arch is carried past the cutter, plainly seen in the photograph, while below this cutter, but hidden from view, are two face mills so located as to mill the inner and outer sides of the rim. Means are also provided for automatically changing the space between these two cutters to allow for the thicker portion of the rim on one side of the arch.

The final operations on the arch are accomplished at one setting on the machine shown in Fig. 11. The casting is clamped to the table in a horizontal position on its back and the pair of cutters mounted on the horizontal slide at the left side of the machine serve to mill the spottings to which the arch stands are bolted, while the pair of cutters carried on the vertical head in the center of the picture finish the spottings on both sides of the flange. In addition to these milling operations, the holes for the capscrews securing the stands in place are drilled and tapped. The table of the machine is revolved by hand to its successive positions under the horizontal cutters, while the vertical milling, drilling and tapping heads are free to swing about the central axis to any desired position. The locations of the various spottings and holes are all determined by tapered slots in the rim of the table into which plungers, mounted on their respective heads, are thrust to locate the spotting or hole to be finished.

Against the outer rim of the arch, the flexible bend, over which the flats travel, is held by its adjusting blocks. It is essential that this bend be close to the milled surface of the arch and its sides must therefore be true and even. The finishing of these sides is accomplished as in the case of the rim of the arch, by feeding the bend between two properly spaced face mills and removing the scale from both sides of the casting at the same time. This operation is shown in Fig. 12. It will be noted that this machine is of a type similar to some of the continuous milling machines which have been recently developed, where the loading and unloading is carried on while the machine is in operation. A rough casting may be seen entering the cutters, while in the rear the finished one is just coming into sight. The cutters are hidden from view in the cut,

The Value of Clean Blast-Furnace Gas

Savings Resulting from the Use of Clean Gas in Hot-Blast Stove and Boiler Operation—Superiority of Dry Cleaning Over Wet Cleaning—Possibilities Held Out by the Electrical Cleaning Process

By N. H. GELLERT,[1] PHILADELPHIA, PA.

THERE are so many factors entering into the general problem of making iron from iron ore that the blast-furnace superintendent is often at a loss to determine which of all of these is most important. The experienced operator has undoubtedly long ago arrived at the conclusion that many contingent, equally important factors make up his general problem, and looks for no panacea to remedy all his ills. Some operators, having tried several remedies, and having failed to find them as effective as originally supposed, have despaired of discovering in the future definite specifics for blast-furnace troubles. Such operators are few today and will be fewer in number tomorrow.

Steel and fuel have made our country strong and powerful among nations. We must look to our continued supremacy in these to maintain ourselves in that eminence of world power to which they have helped to raise us. This supremacy, however, can be maintained only by the most careful conservation of all our fuel resources, so that it may be possible for steel men to produce the sinews of world industry with the minimum expenditure of power.

Our geologists tell us that we are reaching the end of our known fuel resources, and that at the present rate of consumption, the end is measured by scores of years and not by centuries. In view of such a condition, it becomes not only the advisable business policy to effect a rigid conservation of our fuel resources, but the major part of duty also. Such conservation can be effected in a large measure by steel men. Each stage of steel making requires its huge quota of fuel. In each stage of steel making savings can be secured.

We are especially interested at this particular moment, however, with the consideration of the savings to be effected by the cleaning of blast-furnace gas. To this specific consideration, therefore, the remainder of the discussion will be confined.

THE VALUE OF CLEAN GAS IN STOVES AND BOILERS

The value of clean gas as against dirty or raw gas has been so well demonstrated that it might seem superfluous to most blast-furnace men to start any discussion on such a score. The policy of our largest and most progressive steel companies has been definitely established by the expenditure of millions of dollars to install cleaners, so that raw gas may not be fed to the boilers and hot stoves.

If the gas issuing from a blast furnace were a small item, overlooking its importance might be permissible, but the facts are these:[2]

1 Forty-eight to fifty per cent of the thermal value of the coke charged into the blast furnace issues from it in the form of latent and sensible heat of combustible gases.

2 Thirty per cent of the gas generated is used for increasing the temperature of the blast.

3 Sixty per cent of the gas is used in boilers or engines for power.

Consider for a moment what clean gas will do for hot stoves. At Duquesne[3] tests were made on hot-stove operation using gas in three different conditions. The results obtained as given in Table I, are at least interesting.

TABLE I AVAILABLE HEAT IN CLEAN AND DIRTY GAS

Kind of Gas	Dust content, grains per cu. ft.	Moisture content, grains per cu ft.	Temp. of gas, deg. fahr.	Available heat, per cent
Raw gas	3.0	35.0	400	77.03
Partly clean gas	...	saturated	125	71.33
Clean gas	0.2	7.98	70	79.51

Mr. Diehl's conclusions, drawn from a careful investigation of his data, were that at 1913 prices the following savings were made:

1 Increased stove efficiency	$0.0998
2 Saving in limestone	0.0072
3 Saving due to increased production	0.0521
Total saving per ton of iron	$0.1591

Now in none of these figures was any consideration taken of the increased life of the stoves, of the more continuous operation because of a decreased number of cleaning periods, or of the savings due to better combustion and other beneficial results when using clean gas in the boilers. Unfortunately, no really determining data have been made available to enable us to determine just what such savings might be. It is evident, nevertheless, that they must be considerable, as to them must be credited savings (1) in checker brick in stoves, (2) in stove linings, (3) in combustion-chamber brick, (4) in boiler-setting brick, (5) in boiler tubes, (6) in boiler fuel, and (7) in labor cleaning outside of boiler tubes.

Interesting data on boiler efficiencies were given by Mr. Diehl in the paper already mentioned, and results which he has tabulated indicate that when burning clean gas the average thermal efficiency was 66.1 per cent, while when burning raw gas it was 62.3, making a gain of 3.8 per cent when burning clean gas. Since, however, the clean-gas tests were run after the boiler tubes had been cleaned and the whole boiler put in good shape, it is obviously impossible to say just how much of this saving is due to the burning of clean gas. It may be said, however, that the results indicate clearly that a saving is to be procured when burning clean gas, since the removal of dirt from the tubes and the burning of clean gas made it possible to get the high efficiencies recorded. Such a conclusion is checked by other tests reported by Mr. Diehl in which one boiler burning raw gas had an average efficiency of 49.8 per cent, while another burning clean gas—both using common burners—had an efficiency of 51.2 per cent.

DRY VERSUS WET CLEANING

Now if it is conceded, by force of common practice and such data as can be used for argument, that clean gas is to be preferred above dirty gas in stoves and boilers, there remains but one other question to be answered: Shall gas be cleaned by a wet process or a dry process?

Heat Value of Dry-Cleaned Gas. Suppose we consider the operation of a 500-ton furnace here in the Birmingham District. If every ton of iron required 2500 lb. of coke, the total coke tonnage per day will be 625 tons. If we take 48 per cent of this to be in the form of gas, then 301 tons must be used for fuel purposes outside of the furnace. Here is presented a possibility for control that should result in savings.

Now there will be about 170,000 cu. ft. of gas generated per ton of iron made. At a 500-ton furnace this would give 85,000,000 cu. ft. of gas per day, 3,540,000 cu. ft. of gas per hour, or 59,000 cu. ft. per min. at 29.92 in. of mercury column pressure and 62 deg. fahr.

Assume the gas has a percentage analysis as follows: CO_2, 12.5; CO, 25.4; H_2, 3.5; N_2, 58.6. Assume also that the temperature of the gas in the mains is 400 deg. fahr. and the moisture at standard conditions is 35 grains per cu. ft.

The thermal value of the gas depends on (1) its latent heat of combustion and (2) its sensible heat; and if the products of combustion escape at, say, 600 deg. fahr., there will have to be subtracted from the total heat the sensible heat of the escaping products of combustion.

Latent Heat. First consider the thermal value of the gas.

Table 2, the author believes, is the first published attempt to assemble the data given from a number of sources so as to collect the most probable values of the constants involved. In addition,

---

Abridgement of a paper read before the Birmingham Section of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, Birmingham, Ala., October 28, 1921.

values have been calculated to correspond to a temperature of 62 deg. fahr., the temperature at which most technical gas calculations are made.

By the aid of this table it now becomes a fairly simple task to develop the latent-heat value of the gas which is being considered.

We have available 59,000 cu. ft. of gas per minute at 62 deg. and 29.92 in. mercury column. Of this amount 14,986 cu. ft. are carbon monoxide and 2065 cu. ft. hydrogen. The hydrogen has a total latent-heat value of 676,100 B.t.u. and the carbon monoxide a total latent-heat value of 4,771,100 B.t.u., or for all the combustible elements, a total latent-heat value of 5,447,200 B.t.u. per min. See Table 3.

[1] From Olsen's Manual. [2] Calculated. Columns 2 and 3, values from Liddell's Met. and Chem. Handbook; columns 4, 6, 7, 12, and 13, calculated; column 5, values from Poole's Calorific Power of Fuels; column 8, values from Babcock and Wilcox' Steam; columns 9, 10 and 11, from Pratt's Principles of Combustion.

Since, however, the water vapor formed in the combustion of the hydrogen is not condensed in the products of combustion, the lower heat value, 52,920 B.t.u. per lb., should hold. There must therefore be subtracted the difference between these two values for the total latent heat, or (62032 − 52920 =) 9112 × 10.9 = 99320.8 B.t.u. must be deducted, making the net value of the latent heat 5,347,900 B.t.u.

TABLE 3 LATENT HEAT OF COMBUSTION
(59,000 cu. ft. of blast-furnace gas per min.)

Constituent	Per cent by volume	Cu. ft. per min.	Weight per cu. ft. at 62° F., lb.	Total wt., lb.	Per cent by weight	Latent Heat in B.t.u. Per cu. ft. at 62° F.	Latent Heat in B.t.u. Per lb.	Latent Heat in B.t.u. Total
Carbon dioxide	12.5	7375	0.1163	838.3	18.6	...	...	....

Total				4500.7				5,447,200

Sensible Heat. To this, however, must be added the value of the sensible heat of the gas. This may be determined from the formulas given in Table 4, which hold true for values of gases up to 2000 deg. cent. (3600 deg. fahr.) in temperature.

TABLE 4 THERMAL CAPACITIES OF GASES PER POUND FOR TEMPERATURES UP TO 2000 DEG. CENT. (3600 DEG. FAHR.)[1]

Gas	Pound-Calories	B.t.u.
Hydrogen	$3.370 + 0.0003t$	$3.370 + 0.00017t$
Nitrogen	$0.2405 + 0.0000214t$	$0.2405 + 0.0000119t$
Oxygen	$0.2104 + 0.0000187t$	$0.2104 + 0.0000104t$
Carbon dioxide	$0.19 + 0.00011t$	$0.19 + 0.00006t$
Carbon monoxide	$0.2405 + 0.0000214t$	$0.2405 + 0.0000119t$
Aqueous vapor	$0.42 + 0.000185t$	$0.42 + 0.000103t$

[1] Tabulated from data in Richards' Metallurgical Calculations.

We may approach our problem then in one of two ways:

1 We may find the mean specific heat of the gas between the limit $(0-t_1)$, and also the mean specific heat of the same gas between the limits $(0-t_2)$. From the total sensible heat found in the first instance we may subtract the total sensible heat in the second leaving us a net result. Or,

2 We may find the mean specific heat between the limits (t_1-t_2) and use this direct to obtain our net sensible heat. For ease in calculating specific heats the formulas in Table 5 may be used.

TABLE 5 FORMULAS FOR SPECIFIC HEAT

Gas	B.t.u. per lb. per degree
Hydrogen	$3.370 + 0.00017t$
Nitrogen and carbon monoxide	$0.2405 + 0.0000119t$
Oxygen	$0.2104 + 0.0000104t$
Aqueous vapor	$0.42 + 0.000103t$
Carbon dioxide	$0.19 + 0.00006t$

Take 500 lb. of carbon dioxide at 400 deg. fahr., to find its net sensible heat value if it enters a boiler when the air temperature is 70 deg. fahr. by the first method:

Specific heat of CO_2 (0°–400°) = 0.2140

Total sensible heat at 400 deg. fahr. = 0.2140 × 500 × 400 = 42,800 B.t.u.

Specific heat of CO_2 (0°–62°) = 0.1936

Total sensible heat at 62 deg. fahr. = 0.1936 × 500 × 62 = 6,002 B.t.u.

Net sensible heat (62°–400°) = 36,798 B.t.u.

In the above calculation the first method is used since it lends itself to greater clarity of thought and develops information as to the actual degree of heat energy of the gases in their various phases and at their various temperatures.

Now calculating the specific heat of the gas at 400 deg. fahr. the following results are obtained:

	Mean specific heat in B.t.u. per deg. fahr. per lb.
Carbon dioxide	0.2140
Carbon monoxide	0.24526
Hydrogen	3.438
Nitrogen	0.24526
Aqueous vapor	0.4612

Attention is here called to the fact that the specific heats here calculated do not agree with those obtained in later determinations of specific heats. In his Principles of Combustion, Arthur D. Pratt calls attention to the work of Holborn and Henning, Langen, Pier, and Austin, and considers the values as obtained by them the most authoritative for such investigations as we are here making. But since most of the past calculations have been based on Richards, the formulas given by him have been used in the present discussion.

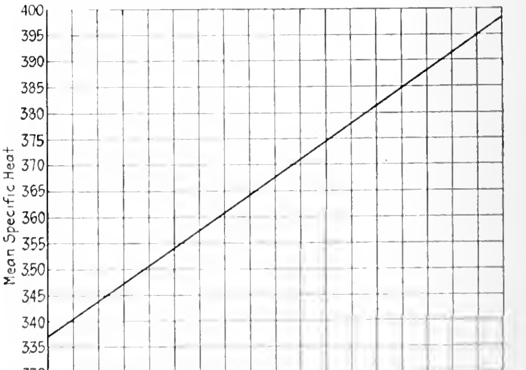

Fig. 1 Mean Specific Heat of Hydrogen between Limits 0 Deg. Fahr. and t Deg. Fahr.

Let us see now how the values of the specific heats may be used in our calculations.

In Table 6 we consider the weights of the components of the gas and the sensible heat they possess by reason of their specific heat at 400 deg. fahr., the temperature at which they are passed through the hot-stove and boiler burners for combustion.

This determination of sensible heat is based on values of specific

heats between the limits 0 deg. and 400 deg. fahr. To get an exact value they should be based on limits—temperature of air and 400 deg. fahr. Since this temperature varies from day to day and season to season, no data developed would hold exactly true. For purposes of comparison the method of determination used should give just as accurate, if not more accurate, results than a method in which daily temperatures must be estimated.

Assume, however, that this average temperature is 62 deg. fahr., the temperature used as a standard for gas-measurement comparison. We can then compute the total sensible heat at limits 0 deg.–62 deg. fahr. as in Table 7, and this subtracted from the sensible heat at the limits 0 deg.–400 deg. fahr. gives:

TABLE 6 DETERMINATION OF SENSIBLE HEAT OF BLAST FURNACE GAS AT 400 DEG. FAHR.

Given 1 Total cu. ft. per min. at 62 deg. fahr. and 29.92 in. Hg dry basis = 59,000
2 Moisture per cu. ft. dry basis 35 grains = 0.005 lb.
3 Temperature of gas = 400 deg. fahr.
4 Percentage analysis, dry basis CO_2, 12.50; CO, 25.40; H_2, 3.50; N, 58.60

Constituent	Per cent by volume	Cu. ft. at 62° F.	Wt. per cu. ft. at 62° F.[2]	Weight lbs.	Per cent by weight	Specific heat at 400° F.	B.t.u. per lb. at 400° F.	Total B.t.u.
CO_2	12.5	7,375	0.1163	838.3	18.6	0.2140	85.6	71,750
CO	25.4	14,986	0.0736	1103.2	24.6	0.24526	98.1	108,220
H	3.5	2,065	0.0053	10.9	0.2	3.438	1375.2	14,650
N	58.6	34,574	0.0737	2548.3	56.6	0.24526	98.1	249,990
[1]H_2O			[4]0.005	295.0		0.4612	184.5	54,430
Total	100.0	59,000		4795.7	100.0	[3]0.2414	996.57	499,040

[1] Aqueous vapor.
[2] Per cubic foot on basis of dry gas.
[3] Average calculated value mean specific heat dry blast furnace gas of above analysis.
[4] Per cubic foot dry gas.

Sensible Heat of Gas at 400 deg. fahr. = 499,040 − 74,390
= 424,650 B.t.u. per min.

TABLE 7 SENSIBLE HEAT OF BLAST-FURNACE GAS AT 62 DEG. FAHR.

Constituent	Weight lb.	Sp. ht. at 62° F.	B.t.u. per lb. at 62° F.	Total B.t.u.
Carbon dioxide	838.3	0.1937	12.0	10,100
Carbon monoxide	1103.2	0.2412	14.9	16,460
Hydrogen	10.9	3.3805	209.6	2,380
Nitrogen	2548.3	0.2412	14.9	37,970
Aqueous vapor	295.0	0.4264	25.4	7,480
Total	4795.7	0.2505		74,390

Total Heat of Gas. The total heat of the gas at 400 deg. fahr. will therefore be:

(1) Net latent heat of combustion	5,347,900
(2) Sensible heat of gas	424,650
Total thermal value	5,772,550 B.t.u. per min.

Combustion Products. Some of this heat will be lost in the escape of products of combustion at a temperature of 600 deg. fahr.

Now in a previous table the most probable values have been used as obtained from a number of sources, while the air and oxygen required were obtained from a source in which air was taken to consist of 23.15 per cent by weight of oxygen and 76.85 per cent of nitrogen. Since, however, our data show oxygen to weigh 0.0841 lb. per cu. ft. at 62 deg. fahr., while nitrogen weighs 0.0737 lb. per cu. ft. at the same temperature, the proportional parts in a cubic foot of air will be as given in Table 8.

TABLE 8 AIR-OXYGEN RATIO

Gas	Per cent by weight	Wt. per cu. ft.	Proportionate volume	Per cent by volume	Air-Oxygen by weight	Ratio by volume
Oxygen	23.15	0.0841	275	20.89	1.00	1.00
Nitrogen	76.85	0.0737	1043	79.11	3.32	3.79
Air	100.00	0.0761	1318	100.00	4.32	4.79

If, therefore, gas be burned by the combination with air, there will be present in the products of combustion, in addition to the new compounds formed, inert nitrogen amounting to 3.32 times the weight of the oxygen combined with the burning gases.

The combustion products when burning carbon monoxide and hydrogen will be as given in Table 9.

It is now possible to proceed with the calculation of the combustion products of the 59,000 cu. ft. of gas at 62 deg. fahr. with which we started our discussion.

TABLE 9 COMBUSTION DATA

		Air Required		Products of Combustion					
				Lb. per lb.			Cu. ft. per cu. ft.		
Constituent	Symbol	Lb. per lb.	Cu. ft. per cu. ft.	CO_2	H_2O	N_2	CO_2	H_2O	N_2
Carbon monoxide	CO	2.47	2.391	1.58		1.89	1	..	1.891
Hydrogen	H_2	34.56	2.391		9.00	26.56	..	1	1.891

By developing the calculations further (see Table 10) we find that when the gas is burned the total products of combustion are:

Carbon dioxide	2,581.3 lb. or	22,361 cu. ft.
Water	393.1 lb. or	8,289 cu. ft.
Nitrogen	4,922.7 lb. or	66,818 cu. ft.
Total products of combustion	7,897.1 lb. or	97,468 cu. ft.

Sensible Heat of Combustion Products. These escaping products of combustion take with them out of the stack and into the air a portion of the heat by virtue of their thermal capacities. To know what heat is available for useful work, the sensible heat of these products must be determined at a temperature of 600 deg. fahr. Using the formulas in Table 6, we are able to obtain the following values bearing on this determination:

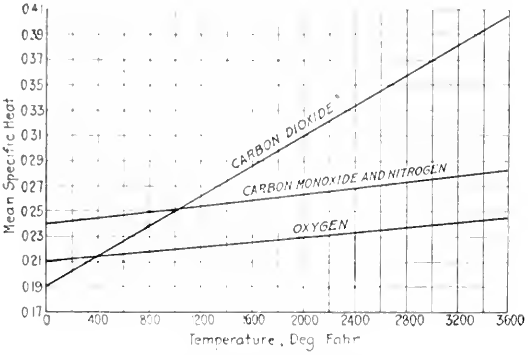

FIG. 2 MEAN SPECIFIC HEATS OF CARBON DIOXIDE, CARBON MONOXIDE, NITROGEN AND OXYGEN BETWEEN LIMITS 0 DEG. FAHR. AND *t* DEG. FAHR.

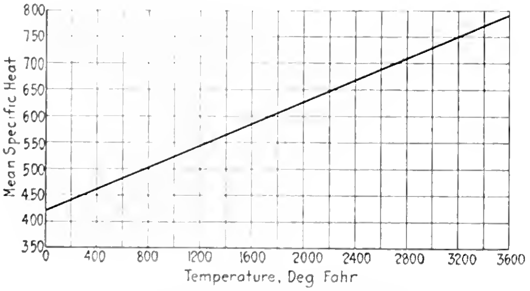

FIG. 3 MEAN SPECIFIC HEAT OF AQUEOUS VAPOR BETWEEN LIMITS 0 DEG. FAHR. AND *t* DEG. FAHR.

	Mean Specific Heat in B.t.u. per Deg. Fahr. per Lb.
Carbon dioxide	0.2260
Aqueous vapor	0.4818
Nitrogen	0.24764

At 600 deg. each pound of product will have 600 times the thermal capacity here shown. The full analysis of the total thermal capacity of all the products can then be developed and this total

TABLE 10 PRODUCTS OF COMBUSTION OF BLAST-FURNACE GAS
(59,000 cu. ft. per min. at 62 deg. fahr.)

		Per cent				Total Air needed		Products of Combustion					
								Total lb.			Total cu. ft. at 62° F.		
Constituent	Symbol	by vol.	by weight	Weight, lb.	Volume in cu. ft. at 62° F.	lb.	cu. ft.	CO_2	H_2O	N_2	CO_2	H_2O	N_2

sensible heat calculated to be 1,194,800 B.t.u., as shown in Table 11.

Here we must make the same corrections as made for the sensible heat of the gas. Our sensible-heat calculations for gases between the limits 0 deg. and 62 deg. fahr. are as given in Table 12 and the net sensible heat of the products of combustion will be 1,194,800 − 114,380 = 1,080,420 B.t.u. per min. We then have:

Total value of the original gas for both latent and sensible heat	5,772,550 B.t.u.
Net sensible heat of the products of combustion	1,080,420 B.t.u
Gross available B.t.u.	4,692,130 B.t.u.
Less 10 per cent lost because of original loss in gas	469,213 B t.u.
Net available B.t.u. per minute	4,222,917 B.t.u.

TABLE 11 DETERMINATION OF SENSIBLE HEAT OF PRODUCTS OF COMBUSTION OF HOT GAS AT 600 DEG. FAHR.

AVAILABLE HEAT AND FLAME TEMPERATURES IN DRY CLEANING

All these figures are based on the assumption that blast-furnace gas is delivered at 400 deg. fahr. to the burners of the hot stoves and boilers. This is, of course, what a dry-cleaning device would enable the operator to do. If, however, he is forced to clean his gas by a wet process there must necessarily be a reduction in temperature of the ingoing gas. This reduction in temperature, it is true, will reduce the moisture content of gas. Whether this reduction in moisture content is of any considerable value, or whether it can compensate for the losses in heat incident to the cooling of the gas, is something that might well be determined. To arrive at a conclusion approaching a semblance of accuracy, two things must be taken into account:

1 The comparison of the flame temperature of the burning gases
2 The comparison of net available B.t.u. of the gas.

We have already started our study of the available B.t.u. of hot gas containing 35 grains of moisture per cubic foot at 62 deg. fahr. and 29.92 in. Hg.

Flame Temperature. Let us consider for a moment the theoretical flame temperature of this gas.

$$T = \frac{\text{B.t.u. produced}^1}{W \times S_m}$$

where T = the elevation in temperature
W = weight of products of combustion, and
S_m = mean specific heat of products between temperature of fuel and air and that of products.

The exact value of S_m cannot be found until the value of T is known. For that reason a trial method of computation must be adopted.

The average temperature of the fuel and air will depend on the temperature at which each was delivered to the point of combustion. The gas was delivered at 400 deg. fahr., the air at 62 deg. fahr., and the temperature of the mixture can be shown to be about 251 deg. This figure is interesting but not necessary to our calculations as we already have the total thermal value of the gas before burning.

TABLE 13 SENSIBLE HEAT OF PRODUCTS OF COMBUSTION PER DEGREE

Constituent	Total wt., lb.	Sp. ht. at 2180° F.	Sensible heat per deg.	Sp. ht. at 2400° F.	Sensible heat per deg.	Sp. ht. at 2380° F.	Sensible heat per deg.
Carbon dioxide	2581.3	0.3388	875	0.3340	864	0.3328	860
Nitrogen	4922 7	0.2700	1330	0 2691	1320	0.2688	1320
Aqueous vapor	393.1	0 6754	265	0 6672	262	0.6651	260
Total		0.2138	2470		2446		2440

Proceeding now to the determination of flame temperature, let us assume 2480 deg. fahr. as the correct value. Then, dividing the B.t.u. produced by the sensible heat per degree at 2480 deg. fahr., as given in Table 13,

$$T = \frac{5{,}772{,}500}{2470} = 2340$$

It is evident that this is the wrong temperature. Assuming 2400 deg. as the flame temperature,

$$T = \frac{5{,}772{,}500}{2446} = 2360$$

Again, taking 2380 deg.

$$T = \frac{5{,}772{,}500}{2440} = 2370$$

For our purposes we may take the halfway point between 2380 and 2370 or 2375 deg. fahr., as the correct flame temperature. Greater accuracy may of course be obtained by another trial.

AVAILABLE HEAT AND FLAME TEMPERATURE IN WET CLEANING

So far there have been determined for the gas which is considered as cleaned by a dry process:

1 A value for the available heat which has been found to be 4,222,917 B.t.u. per min. This is the net value after all losses are accounted for.

2 A value for the flame temperature which is 2375 deg. fahr.

We now approach the discussion of these same values when the gas is wet-cleaned. In this instance the gas will have the same analysis as before but its temperature will be 70 deg. fahr. and its moisture content 7.98 grains per cu. ft. of dry gas at 62 deg. and 29.92 in. Hg.

Latent Heat. Its latent heat will be exactly as before since the heat values of the combustible constituents of the gas have not changed. This gross latent-heat value was found to be 5,447,200 B.t.u. per min.

From this amount there was subtracted the difference between the gross and net value of the heat generated by the combustion of the hydrogen, since there was no condensation of the moisture in the products of combustion before escaping through the stack. In addition there was deducted a 10 per cent loss in gas itself.

With the deduction for the lower thermal value of hydrogen there was a net latent-heat value left of 5,347,900 B.t.u. This holds true with wet-cleaned gas also.

Sensible Heat. When we consider the matter of sensible heat, however, we have some differences to take into consideration.

The mean specific heats of the component parts of the gas at 70 deg. fahr. as calculated by the formulas in Table 5 are as follows:

Carbon dioxide	0.1942
Carbon monoxide and nitrogen	0.2413
Hydrogen	3.3819
Aqueous vapor	0.4272

With these values and such other data as we have already obtained, we may develop a table similar to Table 7 giving a total of 77,620 B.t.u. per min. for the sensible heat of all the gases. The total heat of the 59,000 cu. ft. of gas per min., therefore, is 5,347,900 + 77,620 = 5,425,520 B.t.u. per minute.

Combustion Products. Turning to the consideration of the products of combustion of this gas, we find that all the products will be the same excepting the moisture content which will be less by the difference between 295 lb. as found in gas containing 35 grains of moisture per cu. ft. and 67.3 lb. as found in gas containing only 7.98 grains per cu. ft. This difference is 227.7 lb. The products of combustion will therefore be:

Carbon dioxide	2,581.3 lb. or	22,361 cu. ft.
Aqueous vapor	165.4 lb. or	3,480 cu. ft.
Nitrogen	4,922.7 lb. or	66,818 cu. ft.
Total	7,669.4 lb. or	92,659 cu. ft.

These products must be assumed to escape at the same temperature as before in order to get a reasonably accurate comparison. If the stack temperature is 600 deg. fahr. as before, the specific heats of the products will be the same as before. The total sensible heat of each product will also be the same as before, excepting that of the aqueous vapor. In the previous calculation 393.1 lb. of aqueous vapor had a total sensible heat value of 113,640 B.t.u. or 289.08 B.t.u. per lb. Then 165.4 lb. of aqueous vapor will have a sensible-heat value of 47,814 B.t.u. and the total sensible heat of the combustion products will be: (CO_2, 350,020) + (N_2, 731,320) +

---

[1] From Pratt's Principles of Combustion.

(H_2O, 47,220) = 1,128,560 B.t.u. per min. From this total there must be subtracted the heat energy present at 62 deg. fahr.

This will be the same as before, excepting for the aqueous vapor. In the former case 393.1 lb. aqueous vapor had a heat energy of 9980 B.t.u. per min. Then 165.4 lb. of aqueous vapor which we have to deal with in this latter case will have a heat energy at 62 deg. fahr. of 4190 B.t.u. per min. and the total energy will be: (CO_2, 31,000) + (N_2, 73,400) + (H_2O, 4,190) = 108,590 B.t.u. per min.

The net sensible heat of the products will therefore be 1,128,560 − 108,590 = 1,019,970 B.t.u. per min.

It is now possible to determine our net available heat.

Latent and sensible heat of gas	5,425,520
Less net sensible heat of combustion products	1,019,970
Gross available B.t.u.	4,405,550
Ten per cent gas loss	440,555
Net available B.t.u. per min.	3,964,995

Savings. We have already found that the net available B.t.u. per min. when burning hot gas with 35 grains of moisture per cu. ft. = 4,222,917, and now we have the net available B.t.u. per min. when burning cold gas with 7.98 grains of moisture per cu. ft. = 3,964,995, giving a difference in favor of hot gas of 257,922 B.t.u. per min. or 371,407,680 B.t.u. per day saving in using hot gas over wet-cleaned gas.

On the basis of 500 tons per day the saving will amount to 371,407,680 ÷ 500 = 742,820 B.t.u. per ton. Now Birmingham coke contains about 14,290 B.t.u. per lb. on a dry basis.[1] This would mean that 742,820 ÷ 14,290 = 52.0 lb. of coke is saved per ton of iron made. It is not unfair to take $6 per ton as the price of coke charged into the furnace. Then the saving in the use of hot gas will be (52 ÷ 2000) × $6 = $0.156 per ton of iron made for coke alone.

Flame Temperature. We have now to consider the flame temperature of this wet-washed gas, and then we are through with our discussion as to heat values. Let us assume the flame temperature to have a value between 2000 and 2400 deg. fahr. See Table 14.

TABLE 14 FLAME-TEMPERATURE CALCULATIONS

Constituent	Total lb	Sp. ht. 2000° F.	B.t.u. per deg.	Sp. ht. 2200° F.	B.t.u. per deg.	Sp. ht. 2400° F.	B.t.u. per deg.	Sp. ht. 2380° F.	B.t.u. per deg.
Carbon dioxide	2581.3	0.3100	800	0.3112	805	0.3340	860	0.3328	860
Nitrogen	4922.7	0.2643	1300	0.2667	1315	0.2691	1320	0.2688	1320
Aqueous vapor	165.4	0.6260	100	0.6466	105	0.6672	110	0.6651	110
Total			2200		2225		2290		2290

Dividing 5,425,520 respectively by the values 2200, 2225, and 2290 from that table gives 2460, 2450 and 2370 deg. fahr., and we may therefore accept the flame temperature at 2375 deg. fahr., the mean between 2370 and 2380 deg. fahr.

Curiously enough the flame temperatures of the dry-cleaned and wet-cleaned gases as discussed thus far are the same. Practical experience bears this out also, as Diehl's observations indicate that during reasonable test periods the combustion chamber temperatures are 2040 deg. fahr. on wet-cleaned gas and 2030 deg. on hot raw gas.[2] If the latter had been cleaned, our calculations show it would have had as high a temperature as wet-cleaned gas.

Our discussion on heat values of gas may therefore be summed up as follows:

1 Dry-cleaned gas at 400 deg. fahr. even if it contains 35 grains of moisture per cu. ft. has a greater available heat value than wet-cleaned gas at 70 deg. fahr. and 7.98 grains moisture per cu. ft. This heat is 6.5 per cent greater for the former gas than for the latter. At $6 per ton for coke charged into the furnace it means a saving of $0.156 per ton of iron made, in favor of using hot-cleaned gas.

2 There is no difference in flame temperature between the two gases.

Savings Due to Dry Cleaning

We have taken up at great length the question of net heat values of the gases. There are, however, many more factors to be considered in the discussion of wet versus dry cleaning. These factors will be dealt with only briefly at this time.

The costs of wet versus dry cleaning are of interest. If we take the cost of water to be 3 cents per 100,000 cu. ft. of gas cleaned we will be figuring below the average. Let this, however, represent the cost of cleaning the gas, as labor items will be alike for both wet and dry cleaning.

Now, in the dry-cleaning plant about to be described there is but one expense outside of labor, namely, the power cost. Since about 0.3 kw. is used per 100,000 cu. ft. of gas, if power is charged at 2 cents per kw., the cost of cleaning will be 0.6 cent per 100,000 cu. ft. of gas. This means a saving of 2.4 cents per 100,000 cu. ft. or 4.1 cents per ton of pig iron made.

It is, of course, impossible to calculate in dollars and cents all the benefits to be derived from the dry cleaning of gas, as there are factors on which accurate data cannot be obtained.

If, however, we consider the factors already discussed for which a money approximation has been developed, we find

	Per ton pig iron made
Saving due to use of wet-cleaned gas in hot stoves over raw gas	$0.159
Saving in thermal value due to using hot clean gas over wet clean gas	0.156
Saving in operating dry over wet cleaner	0.041
Total calculable saving	$0.356
Estimated saving in using dry clean gas over wet gas in boilers	0.050
Estimated saving in hot-stove brick, boiler brick, etc.	0.060
Total calculable and estimated savings	$0.466

When making 500 tons of pig iron a day, these savings become—

	Calculable	Estimated	Total
Per ton pig iron	$0.356	$0.11	$0.466
Per day (500 tons)	$178	$55	$233
Per year (365 days)	$64,970	$20,075	$85,045

We have then definitely calculated savings of $64,970 per year, not including increases in boiler efficiencies and increased life of boiler tubes, boiler settings, stove checkers and stove linings.

If we are willing to accept the estimated savings which the writer believes are conservative, then an additional $20,075 may be credited to the dry cleaning of gas as against raw gas. The total savings then are $85,045 per year. The calculable savings are about 60 per cent return, and the total savings about 80 per cent return, on the cost of a dry cleaner.

One other benefit to be obtained by dry cleaning is that there is no effluent problem. Two methods of handling the discharge of a wet cleaner are open to the operator. He may empty it into a stream, or he may recover a large amount of the sludge and discharge a more or less muddy effluent into the stream. In either case he discharges a nuisance. If the stream is polluted he may be restrained by law from killing, by cyanide in solution, anaerobic bacteria which digest the contamination and prevent its becoming a nuisance. If the stream is not polluted he may be restrained by law because of his being a public nuisance.

There therefore seems to be no brief for the wet washer as against the dry cleaner. Far-looking blast-furnace men have realized this for years. Some have had enough daring to pioneer for the dry cleaner, and to them belongs a large measure of credit for what dry-cleaner men have accomplished in the last few years.

Electrical Cleaners

The writer has in a previous paper discussed dry cleaners in general, and has given detailed descriptions of the electrical cleaners now in use.[1] Those who are interested in the details are referred to that paper.

There are now operating—or were before the steel industry had to take a vacation—two electrical cleaning plants.[2] These are commercial units which have been operating under as severe conditions as any cleaner can be subjected to. They have regularly been cleaning gases up to 900 deg. fahr. in temperature, under conditions of slip and subject to all the other irregularities of blast-furnace operation. Such difficulties as were first encountered, common to all new undertakings, were overcome long ago and one of them is now in its third year of operation.

Under the best conditions they have cleaned gas to less than 0.1 grain of dust content per cubic foot, and under difficult conditions to 0.4 grain per cubic foot. They have handled gases directly from the dry-dust catchers with dust contents varying up and down as is common in blast-furnace gas.

These cleaners are built on the electrostatic principle, and in sim-

[1] Electrical Cleaning of Gases as Applied to the Blast Furnace, Phila. Section A.I.S.E.E., Nov., 1919.

[2] One at plant of American Manganese Mfg. Co., Dunbar, Pa., and one at Sheridan Furnace, Lavino Furnace Company, Sheridan, Pa.

ple form may consist of a single vertical pipe with a chain suspended through its center. This chain hangs from an insulator, while the pipe is grounded. The chain is connected to a mechanical rectifier, acting as a high-tension commutator and converting alternating current to unidirectional current. This high-tension alternating current is supplied at from 30,000 to 35,000 volts by a transformer built especially for this work. The current from the transformer is furnished through a switchboard from the plant power lines at single phase and low tension. Three-phase current is supplied to the synchronous motor operating the rectifier.

A full-fledged electrical cleaning plant contains a small substation in which switchboards, rectifiers, motors, resistance and transformers are located. This house may be elevated or not, as desired, and occupies but a small amount of space.

All the electrical equipment is installed in units. The high-tension pieces are thoroughly caged and the operator is guarded by interlocking electrical devices. Only low-tension equipment is available to him for operation when the current is on.

The cleaners themselves are of steel, vertically built in small cylindrical units filled with tubes and chains—one chain for each tube. They are compactly built and have a high structural factor of safety to withstand excessive temperatures.

Operating a cleaning plant is simple. Gas may be discharged into the cleaner under its header plate from which the tubes are hung. It will pass down around the outside of the tubes and up through the tubes into the top of the cleaner, thence out to the hot stoves and boilers. As long as the current is off this gas will be uncleaned. Now if the rectifier is put into operation so that it may be in shape to convert alternating to unidirectional current at high voltage, the single-phase current may be impressed on the transformer. The corona discharge will then take place from the negative electrodes to the pipes and cleaning will begin, and as there is no complicated mechanism to operate, an unskilled workman handles a whole battery of cleaners as they are controllable from one substation in which he is located.

When cleaning has proceeded for one-half to one and one-half hours, depending on the dust content of the gas, the current is taken off and the pipes are rapped. This causes the dust to drop to the bottom of the cleaner into the hopper devised for that purpose. At the end of the day the hopper may be emptied into a car or conveyor system as desired.

Since the tubes have a total cross-sectional area greater than the mains leading to the cleaners, there is no greater back pressure than is found in the mains.

The cleaners are rapped one at a time so that most of the plant is operative during the cleaning periods. To make rapping as easy as possible, automatically controlled and operated mechanisms have been developed to close the dampers, cut off the current, rap the pipes and chains, open the damper and put on the current intermittently and successively on all the units.

One man can handle a whole battery of cleaners as they are controllable from one substation in which he is located.

All this goes to make possible a departure from past experience.

* * *

In the discussion following the presentation of the paper the author, in reply to various queries, stated that 6 to 7 units of 8 ft. 9 in. diameter would be proper for a 500-ton furnace and that each unit contains ninety 6-in. pipes. The units operated from an hour to an hour and a half before they had to be stopped and the dust knocked down, dependent upon the condition of the gas. If the gas dirt came about 2 to $2^{1}/_{2}$ grains it would be necessary to rap only about every hour or hour and a half. The rapping only takes about 20 seconds and about one minute if done by hand. Precipitators are now designed to handle gas at 15 ft. per sec. In cleaning ferromanganese the dry cleaner does not get rid of all the manganese fumes; if manganese fumes were a true gas it would not catch this gas. On pig iron it cleans to less than one-tenth of a grain, and he was sure that it would clean to two-tenths of a grain regularly if properly designed.

Mr. Swann stated that based on his experience with electric furnaces at Anniston manganese fume was a true gas. He further stated that he was operating electric precipitators on phosphoric acid and obtaining 85 per cent clean-up and had had practically no trouble with the electrical part of the installation.

MODERN SHOP PRACTICE IN BUILDING REVOLVING FLAT CARDS

(Continued from page 304)

but are mounted on the ends of the spindles, one on each side of the machine. Large-diameter pulleys for driving the cutters are mounted directly on the outer ends of these spindles. This method of driving a milling cutter directly by means of a belt has been found very efficient inasmuch as it eliminates vibration and tendency to chatter caused by a gear drive, the belt producing a certain cushioning effect, and cutters thus driven require less frequent grindings and may be operated at a higher speed than those driven through a train of gears.

Power for driving the card is applied to the main cylinder shaft where a pair of 20-in. tight- and loose-webbed pulleys receive the belt. On the other end of the shaft an 18-in. pulley serves to drive the lickerin and flats. These pulleys require a considerable amount of machine work inasmuch as each is made with one or more grooves on one side for driving a round belt in addition to the crowned face. The outer sides of the webs are also turned. A special lathe, Fig. 13, was developed for doing this work by forming tools which carry cutters the full width of the surfaces to be finished. Special attention is called to the massive design of this machine, the headstock spindle being 16 in. in diameter. The heavy heads absorb all vibration even under the heaviest cuts. A special tool block is arranged for each operation, two of which are shown at the base of the machine, the one at the left being used for forming the web and rim, while that on the right blocks out the grooves and half of the crown, the other half being finished in a second operation by turning the pulley around. A spring chuck clamps the pulley securely in place while turning. This machine also carries a boring bar by which the hole is bored and reamed while the turning operation is going on. The average time for finishing the pulley shown at the left of the machine is 11 minutes.

The boring out of the ends of the lickerin shell also proved to be an operation which could not be readily or economically performed on a commercial type of tool and many of the milling operations on the various smaller parts of the card are such as to require the use of gang or form mills.

Coming now to the erecting room, the cards are set up here in rows of twenty-five each as shown in Fig. 14. They are completely assembled with the exception of the clothing and the flats and are then run off and carefully inspected before boxing. Dowel pins are provided wherever necessary so that the work of assembling at the mill is reduced to a minimum.

From the foregoing descriptions and machines which have been illustrated, there are several points to which attention should be called. First, the all-important problem is to get the actual labor cost per piece as low as possible, consistent with the high standard of quality required. This problem is somewhat different from that of most production shops where the low cost of production is arrived at by getting as large a production per machine per day as possible. Many of these special machines are capable of turning out two, three and even four times the amount of work required and are therefore often stopped from one-half to three-quarters of the time. It has therefore been found advantageous to arrange the machines in groups so that one man by operating the group will produce the amount of work required from the machines in his group.

Second, in designing the special machines it will be noted that extremely liberal dimensions have been allowed, and that the lathe and milling-machine spindles have been made to approximate as nearly as practical the diameter of the work to be turned, or the cutter carried by the spindle. In many instances these spindles are made of cast iron, running in bearings of the same material, the surfaces of which when glazed over are almost impervious to wear. The large masses of metal in these spindles and other parts have been provided so as to absorb all vibration and prevent any tendency to chatter even under heavy cuts and feeds.

Third, each machine is designed to do one or more operations on one special part and is suitable for no other purpose. Equipment of this kind is possible only where the product has been thoroughly standardized and is not subject to major changes in design.

Maintenance of Textile Machinery

Purpose of Ball Bearings and Importance of Proper Lubrication Common Abuses and Suggested Corrections

By EDWIN H. MARBLE,[1] WORCESTER, MASS.

A MEMBER of a well-known firm of appraisal engineers recently stated that it was not practical to adjust values of textile machinery by any known annual depreciation percentages. Two machines placed in operation in different mills, receiving attention or lack of attention, will be represented on the valuation sheet by quite varying figures. It is the hope of the writer of this paper that some suggestion may be made that will bring the two valuations nearer together and assist in a better maintenance of the textile machinery that has been installed in so many of the mills.

While there is a difference in the character of the machinery used in the various processes incident to the manufacture of fabrics, the mechanical principles are the same, and adjustments or regulations are very similar for all types of machines.

We will take for specific illustrations that class of machines with which the writer is most familiar, namely, cloth-room machinery. The suggestions, however, will apply equally well to most of the machinery found in our textile mills. When machinery is being constructed by the builder, the frame is carefully leveled and the various bearings are adjusted and the machine when placed in its proper position on the mill floor should be carefully leveled and then securely fastened in its position. Several times we have had called to our attention a very careless carrying out of this suggestion. "The legs seem to be firm on the floor and the machine must be all right," was the report. This leveling is particularly important with machinery that has considerable length along the line of the main driving shaft, such as spinning frames, or with machines that have fine adjustments, such as shearing machines.

Having attended to this particular feature at the installation of the machines, it is well to repeatedly test out the stability of the leveling from time to time, particularly when the installation is in a new mill where the floors have not assumed permanency.

With the machine in position and various attachments and revolving parts in place, see that the bearings are not too snug and that each roll or shaft turns freely. We all expect a certain degree of stiffness in new machines and no matter how finely the builder may have made his fits, the transferring of the machine from one floor to another will have varied the adjustment to some extent, and a slight readjustment may be necessary.

With the machine starting off smoothly, what suggestions can we make to assist in maintaining its operating condition? Lubrication is possibly one of the prime considerations. Often it is no oil, an unstable oil, or a surplus of oil. The same oil cannot well be used on the high-speed spindle and the slow-revolving main shaft. The type of bearing may not be suitable for some of the heavy non-fluid oils. A regular system of oiling up should be practiced. Every morning the operator should see that any exposed oil holes are carefully cleared out and enough suitable oil applied to lubricate each bearing.

Oftentimes you will see on an automobile oiling chart, *A*, *B*, and *C* are to be oiled every five hundred miles; *H*, *K*, and *M* once in a thousand miles and by this means the maker of the auto endeavors to educate the owner in maintenance of his purchase. And more than that he specifies the quality of oil he thinks it best to use.

The textile-machine builder would like to furnish a similar chart and specify the grade or quality of oil, but the conditions under which his machines are used are so entirely different that it is not considered feasible.

However, requests for such charts have been received and it may be possible to construct such a chart at some later date.

On many textile machines, you will find ball bearings of various makes and they require considerable attention. First, we would ask why were these particular devices installed? Reducing all the answers to their lowest terms we find three reasons; they reduce bearing friction and save horsepower; they render good service by the saving of oiling troubles; or they were installed because some salesman convinced some one that he had a panacea for most of the ills mechanical devices are troubled with. The first answer is a rather limited one, for while the actual saving of horsepower is in many cases quite an item, the application of ball bearings to a particular revolving body should be considered carefully and the condition of working load examined and charted before any new installations are made.

In almost all cases the machine builder has looked the designing of his machine over pretty carefully before he has sent it out and is a fairly good judge of when and what kind of a friction-reducing bearing can be used to advantage.

Now regarding the second reason, which concerns the lubrication side of the ball-bearing question, any ordinary bearing must be oiled frequently. The installation of a proper ball bearing will in many cases reduce to a considerable extent both the time required to oil and the amount of oil used. The frequent oiling of ordinary bearings oftentimes breeds carelessness, and the surplus oil, conveyed to stock or fabric, produces damaged goods. This can be prevented in a great measure by a careful consideration of the application of a suitable friction or lubricant retaining bearing.

But don't for one moment think your troubles are ended when your ball bearing is installed. A ball bearing allowed to run dry can do as much damage as can any other type of dry-running bearing and perhaps from a financial point of view much more damage. We cannot attempt to tell how often a ball bearing should be repacked with suitable heavy oil or grease. The load under which it runs, the speed of the shaft and type of lubricant retaining washers or felt that is used, all have an influence on this. Three or four times a year may be necessary for one bearing, while another bearing can be allowed to run for six months without injury. But plainly speaking, every bearing must receive attention or your maintenance costs mount upward rapidly.

In the textile industry more than in any other, the ball-bearing salesman seems to have found a large number of gullible customers. Draft rolls on a cotton-brushing machine, approximately $1^{1}/_{2}$ in. in diameter, revolving 60 to 100 turns per minute, have been equipped with expensive self-alignment, self-adjusting, felt-washered, oil-retaining bearings, guaranteed to reduce the horsepower required to run the machine from 30 to 50 per cent. The large percentage of the horsepower required is consumed in drawing the cloth through the machine. The friction load on the bearing is very small and rarely have we seen any noticeable saving in power by such an application. On the other hand we have noticed on some machines ball bearings subjected to a heavy working load that have failed to stand up; due to not understanding the conditions or afraid to ask too high a price for the installation, the salesman had equipped the machines with bearings much too light for the duty required. Hence when in doubt about ball-bearing equipment on an old type of textile machine, ask the maker.

Many machines receive power in some of their parts, through friction clutches, and few mechanical movements have been subjected to so much abuse as have these devices. From a standing position you throw into action from $^{1}/_{2}$ to 10 hp., and expect an immediate response at approximately full speed. Promptness of action is demanded, yet little attention is given to the mechanism that must respond to the demand. The cone, or actuating part, is probably scored by the lever being too tightly pressed against it; as the clutch is handled the starting load is in excess of the best efforts of the friction band. Most clutches are designed to produce a pressure rapidly increasing toward the end of movement, yet the movement is often so rapid that the start is not made until the

[1] President, Curtis & Marble Machine Co., Mem. Am.Soc.M.E.

For presentation at the Spring Meeting, Atlanta, Ga., May 8 to 11, 1922, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, 29 West 39th St., New York, N. Y. All papers are subject to revision.

extreme throw is completed. Through severe use the friction-creating surfaces are roughened so that instead of a gradually increasing friction application, the action is a grip or bite, demanding an immediate response on the part of the standing portion. Every application of the lever increases the roughness and necessitates more serious consideration of the remedy which eventually must be applied.

Give a little attention to the friction creating surfaces, cleaning them from gum or grease, smoothing any irregularities that may have been formed and particularly adjusting the toggle or connecting unit between the cone or actuating part. In fact, see that the clutch, as a whole, is in condition to respond to the call for its services. You are not dealing with a yielding movement like a leather belt, but rather a somewhat rigid device that depends on the frictional contact between two metallic surfaces for the transmission of energy—a splendid device when properly cared for, but usually one of the most abused attachments on any textile machine.

The moment any one says, "Use belting in a textile plant," some one else has his dissenting viewpoint. Every belt has to adjust itself in passing over a pulley, according to its thickness and flexibility. A stiff, thick belt on a small pulley is giving the operator about 60 per cent of the value of the proper belt. An overcrowned pulley of small diameter is another loss of power. Any piece of leather or perhaps canvas is good enough to transmit power, seems to be the idea of some of those in charge of textile plants, and one will find stiff and non-flexible belting being used to transmit power to a series of rollers running at a high speed and equipped with comparatively small pulleys. The result is that the belt will not conform to the arc of the pulley and hardly has time to straighten itself after leaving one curved surface before it must reverse its curvature in going around a second pulley. A pliable single belt of good quality will transmit more power and maintain more uniform speed. Then belts are often put on with little attention to conditions. The leather is stiff, dry and without flexibility and the belts are united by heavy hooks or plates, driven into the leather, with the ends probably not cut off square, so that the joint is irregular. Anything to get the machine started seems to be the policy, and yet every dollar saved by this poor method means several dollars lost in effectiveness of the machine.

Perhaps a final word will suffice about belt hooks, lacing, plates or other means of connecting the ends of belts. The nearer the joint is to the thickness of the belt and the more flexible its character the better.

How many machines are deprived of much of their usefulness by a disregard of the small things which enter into their construction. A thumbscrew may hold some attachment in position; it is lost and a piece of string or frequently a strip of cloth is used in its place. This makeshift is so inadequate that more or less loose motion continually takes place, and due to the resulting constant wear the attachment is soon either discarded or becomes inoperative. A cover is flopping about because some one broke the hinge or tore it from the wood or ironwork. Even a belt shipper is rendered unsafe by the wearing of the retaining section. We find shipper levers retained in place by a stick or block of wood and the discovery of this condition by a safety inspector prevented serious accidents in two cases known to the writer. "A stitch in time saves nine" can be applied to mechanical devices as well as to a pair of trousers.

Have any of you noticed the treatment which bearings receive in different textile plants? A driving shaft of suitable size has been installed on a machine by the maker. It is subjected to some hard usage, runs at a somewhat high speed and is carried in well fitted bearings lined with some anti-friction or babbitt metal. It may have been $1^{15}/_{16}$-in. diam. originally but neglected by the oiler eventually both the shaft and babbitt wear down and you have perhaps a $1^{13}/_{16}$-in. shaft running in an oblong hole 2 in. by $2^{1}/_{8}$ in. The result is a worn shaft wobbling around in a somewhat restricted space. At last the operator or foreman succeeds in calling a mechanic's attention to the condition and when the latter has time he takes out the shaft, removes it to the machine shop, finds it is out of round, turns it over to any odd size, takes off the bearings, knocks out the old babbitt and proceeds to rig up some blocking to rebabbitt. Without taking pains to center the shaft or to line up the bearings, he pours in his metal, chips off the surplus and repeats the operation on the cap to the bearing. He then endeavors to replace the bearing in its old position but not being true in alignment, he either packs up his bearing or the cap with cardboard or paper and finding he can turn the shaft in its revamped housing, goes off contented, "with other worlds to conquer" before him. Now this is not a notion or fiction, but has been found by the writer in more than one case. Let us suggest a plan of procedure. Turn your shaft to some special size, and carefully center the shaft in the bearings while they are in position. Then pack up under the shaft so as not to occupy quite one half of the bearing, pour your bearing, and repeat the operation with the cap, packing up the ears to the cap so as not to have a full half of the shaft in the cap. But remember one thing, the shaft that you use to babbitt the boxes in has been subjected to considerable heat. Take it back to the machine shop, true it up and then scrape your babbitted bearings to this straightened shaft until you have a good running fit. See that you have cut new oil grooves in both box and cap and on leaving your completed job, quietly suggest to the operator that a little more attention to lubrication would assist you indirectly.

Many of the incidents herein cited occurred during several recent visits of the writer to textile mills in the South and perhaps their presentation here will result in lessening the evils and abuses to which textile machinery is frequently subjected.

Hydroelectric Power Development on the Kings River, Cal.

One of the largest hydroelectric power development projects for which the Federal Power Commission has recently granted a license is that to be undertaken by the San Joaquin Light & Power Corporation on the North and West Forks of Kings River, Cal. An ultimate installed capacity of 266,000 hp. is planned, and if the present rate of growth in power consumption in the vicinity of the project continues, it is expected that it will be necessary to make the total capacity available by 1930.

The project, which will involve an estimated expenditure of \$51,000,000, will occupy about 14,000 acres of land in the Sierra and Sequoia National Forests. It will consist of three storage reservoirs designed to provide a combined storage capacity of 204,000 acre-feet; eight diversion dams ranging from 15 to 80 feet in height; and nine conduits of which 34 miles will be tunnel and one mile open ditch. Of the seven power houses planned, two will be built into storage dams and will operate under variable heads, the maxima being 175 and 245 ft., respectively; three will operate under heads of 365, 1420 and 1430 ft., respectively; and two, which will be among the very few plants in the United States operating under heads exceeding 2,000 ft., will operate under heads of 2,350 and 2,380 ft., respectively.

The main construction program is divided into five parts, for each of which the time of commencement and completion has been fixed subject to later modification with the approval of the Federal Power Commission, as follows:

Balch Development No. 1, May, 1922—June, 1924
Haas Plant, April, 1924—June, 1926
Kings River Plant, January, 1926—June, 1927
Balch Development No. 2, April, 1926—June, 1928
Farnham and Meyer Plants, April, 1927—June, 1929

Construction of the remainder of the project will be undertaken when market demands have grown to the extent which will warrant installation of additional capacity.

The developed power will be fed into the company's present transmission system through its substation at Sanger by means of a 110,000-volt transmission line to be built in two parallels, one of which will carry a single 3-phase circuit on wood poles, and the other, two 3-phase circuits on steel towers.

The entire development is covered by the license, but its provisions as to storage do not become effective until the corporation secures from the California department of public works the right to store water for power purposes. It now has the right to use the natural flow of the streams on which its diversion dams are to be built, except of Rancheria and Bear Creeks, tributaries, respectively, of the North and West Forks of the Kings River.

Extraction of Oil From Vegetable Matter

Together With a Description of the Operation of the High-Pressure, Yielding-Plunger Pump

By JOSEPH DAVIDSON,[1] ATLANTA, GA

THE vegetable-oil industry in the United States has grown from practically nothing forty years ago, until today there are about 800 mills in the Southern States, producing oil from cottonseed, and about 100 mills in other parts of the country producing oil from various other oil-bearing materials, such as linseed, corn germs, peanuts, soya beans and copra.

The growth and importance of the vegetable-oil industry in this country may be judged from the facts that the present investment represented by the industry is approximately $200,000,000, and the normal amount of oil now produced annually is approximately 2,500,000,000 lb., requiring the crushing of approximately 5,800,000 tons of seeds and other vegetable oil-bearing material.

The methods and machinery used, while considerably improved, are much the same in principle as they were forty years ago. To some extent the oil has been extracted by the solvent process, in which the mass of ground oil-bearing material is treated with a solvent which dissolves the oil and carries it out of the material; the solvent is then evaporated from the oil and used over again.

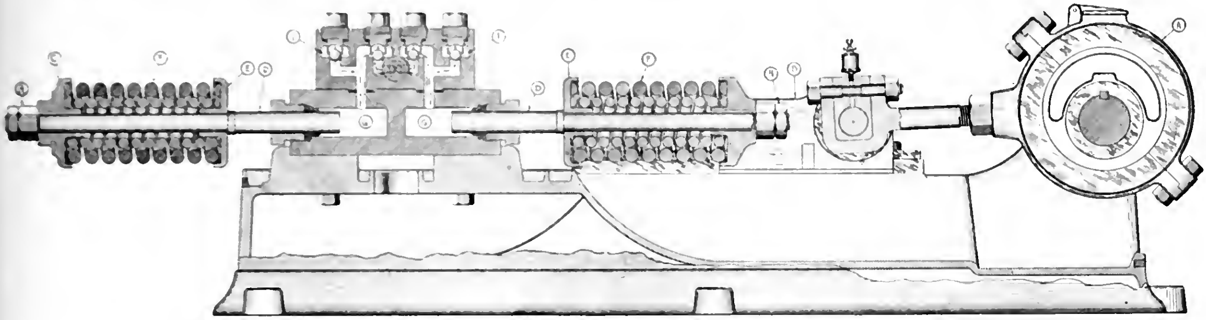

Fig. 1 Longitudinal Section Through High-Pressure Pump with Yielding Plungers

There is also in use to some extent a machine for extracting the oil by forcing the material under great pressure through a slotted barrel by means of a rotating screw.

However, the great majority and the most successful mills are still extracting the oil by hydraulic pressure. In this method the cooked or tempered material is formed into oblong cakes with an outer covering of cloth by a cake-forming machine operated by hydraulic pressure. The oil is forced from the material through the cloth, thence through the perforations and slots of the press boxes, and is collected in a suitable receiving tank. The pressure used against the ram in the press cylinder is 4500 lb. per sq. in., which exerts a pressure of approximately 2000 lb. per sq. in. on the cakes of material being pressed.

It has been found that the manner of applying the pressure has a very important bearing on the efficiency of oil extraction, and also in the economy of the cloth used for covering the cake.

A high-pressure yielding-plunger pump has been designed and put into general use, and has proved to be one of the most decided improvements recently made. This pump applies the pressure in a manner which gives a greater efficiency in oil extraction and saving in press cloth than any yet obtained in the hydraulic method.

A simple low-pressure pump is also used with plungers having a constant stroke, working in connection with a weighted accumulator and by-pass valve, which maintains a pressure of approximately 600 lb. per sq. in. This supplies the pressure in large volume up to 600 lb. per sq. in. on all presses, and also supplies the pressure for operating the machine that forms the material into cakes, preparatory to being put into presses.

Referring to Fig. 1, the eccentric *A* imparts a reciprocating motion to the crosshead *B*. Yoke *C* is connected to crosshead *B* by means of two rods (one on either side, not shown in this figure) and moves fixedly with crosshead *B*. The two plungers *D* are fitted loosely, one in *B* and the other in *C*. Each plunger *D* has a collar *E* fitted against a shoulder. Between these collars *E* and the crosshead *B*, in one case, and the yoke *C* in the other, is placed a double-coil spring *F*, which receives the thrust of the plungers. The initial tension in the springs will stand a pressure of approximately 1800 lb. per sq. in. against the plunger without yielding, but when the pressure in the pump barrels *G* reaches 1800 lb. per sq. in., the springs will begin to yield, and continue to do so, more and more, as the pressure increases. Thus the stroke of the plungers is gradually reduced until the maximum pressure is reached, when they will cease to move; then the maximum pressure is held constant until the extraction of the oil is completed. The pressure is then released, and the cakes discharged from the press, which is then refilled for another pressing operation.

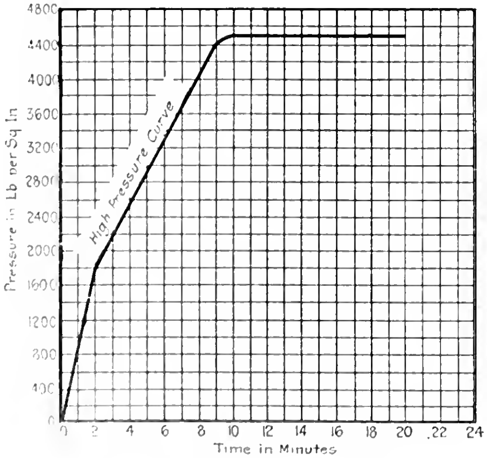

Fig. 2 Diagram Showing Pressure Curve

The pump can be set to maintain any maximum pressure desired, between the limits of 3000 and 5000 lb. per sq. in., by adjusting the nuts *H* on the ends of the plungers *D*. When this adjustment is once made, the plungers will continue to maintain

the same maximum pressure for a long period of time, without any further adjustment of these nuts.

Each chamber *I* around the discharge check has a $\frac{1}{2}$-in. discharge connection, and the common practice in applying pressure to vegetable-oil presses is to run a separate and independent $\frac{1}{2}$-in. pipe from each discharge connection to a press. Thus the high pressure on each press is supplied independently by one plunger, the pumps being constructed so as to provide one high-pressure yielding plunger for each press to be served. These $\frac{1}{2}$-in. high-pressure pipes are connected directly to each press cylinder, no valve being required to cut off the pressure. Each press is equipped with an inlet valve for low pressure and a discharge valve; also a check to prevent the high pressure from leaving the press cylinder through the low-pressure inlet valve. When the discharge valve on the press is closed, the high pressure is confined and builds up the pressure to the maximum required. The springs supporting the plungers are then in action, taking up the movement of the crosshead. When the discharge valve is open while the cakes are being discharged and the press boxes refilled, the plungers are moving full stroke and the springs are not being compressed; the volume of liquid being moved by these plungers merely circulates under no pressure through the press cylinder, and out of the open discharge valve, back into the tank supplying the liquid to the suction of pump.

The use of this pump in supplying pressure to the presses used in the vegetable-oil industry obviates the necessity for any outside controlling devices such as safety valves, retarding, or choker valves, etc.

The power required is the minimum for the amount of work being done. The peak load comes when the pressure reaches 1800 to 2000 lb. per sq. in., and while the plungers are still moving full stroke. But from the moment the plungers begin to yield, and the pressure continues to rise until it reaches the maximum, and the plungers cease to move, the power required decreases; so that the maximum pressure is maintained with little more power than is actually necessary to overcome the friction of the moving parts of the machine.

Fig. 2 shows the pressure curve obtained by this pump when the plungers are making 60 strokes per minute.

This constantly and gradually increasing pressure, especially above 1800 lb. per sq. in., secures the maximum oil extraction due to the fact that the density of the material being pressed is increased very slowly. This gives time for the oil to be forced out of the material, with the least possible resistance which would be set up in case the density was increased too suddenly by a rapid rise of pressure.

The minimum wear and tear on the cloth in which the material is folded is also secured, due to the cake's being much less distorted and exerting much less force against the unsupported parts of the cloth than is the case when the pressure is applied too rapidly.

The Southern Worker—His History and Character

How Industrial Life is Affected by the Development of the Cotton-Raising Industry; the Need for Vocational-Training Schools, Industrial Leaders and General Education

By FRANK H. NEELY,[1] ATLANTA, GA.

THE Odyssey of the southern worker is the story of his wanderings brought about by various economic and industrial changes that the South has undergone in the last one hundred or more years. The tale is picturesque in setting, emotional in action, and certainly inspiring in its present denouement.

Scattered loosely over a large territory, we find in the year 1800 many districts whose inhabitants are artisans, come over from England, Scotland, Ireland, Germany and Holland. These people were essentially of a manufacturing turn, and made of the South an industrial country, so much so, that up to 1810 the manufactured products of Virginia, the Carolinas, and Georgia were greater in value and variety than those of all the New England States.

This aspect continued until the invention of the cotton gin in 1793 by Eli Whitney which changed the whole face of the picture. Almost immediately cotton raising proved of such profit that all manufacturing was stopped and the artisan had in reality "lost his job." He was not an agriculturist, but wanted a high wage for a new pursuit which he was not able to control because of different training and lack of sufficient numbers. Cotton raising was so profitable that it behooved the southern planter to acquire all the land and slaves he could, as cotton brought over twenty-five cents per pound during the next forty years. The artisan was forced by this development to move farther back away from the plains, which were highly suitable for cotton raising, toward the mountains, where he formed a social group, with manners and customs of his own. He made now only the articles that he needed for the use of his family, for the slaves were taught all the homely arts that were needed for life on the plantations.

By 1860 these people were thoroughly settled near the foothills of the Blue Ridge where they became small farmers raising some cotton and grain, and carrying on small trades.

The call to arms in 1861 was answered not only by the men, but also by all boys who had reached the age of sixteen. After the four years of struggle, the man power of the South was depleted, plantations devastated and neglected, railroads torn up, bridges wrecked, the whole country, battle-scarred and desolate. Men straggled back to towns that were no more, living was precarious; men were broken in body and spirit, and their land and tools in no condition for the resumption of work.

Among those who formerly were in condition to help the less fortunate there was scarcely any difference, for the whole economic and social structure had been upset by the abolition of slavery.

The emergence from this condition was necessarily slow. The transition from an agricultural country employing slave labor to one semi-agricultural and manufacturing was difficult, and the years 1865 to 1872 were unfruitful in the development of manufacturing establishments.

However, one by one, cotton mills were built, and once more these artisans of the years before slavery came into their own and began to be what they now are, the foundation of the cotton-mill industry.

These first mills, then, and their builders were heralded at that time as the saviours of widows and children, who were largely without means of support, and the editorials of the day lauded the enterprise of these men and looked upon their activities as a godsend to the South and its population.

The Southern Worker

The characteristics of the industrial workers of the South make them at the same time good and bad factory artisans. Living largely in the mountains and by means of their own devices, they have had only such necessities of life as a poorly managed and fertilized farm would yield. Having no educational advantages, they are ignorant, in many cases illiterate; having for generations lived to themselves, they are sometimes unmoral, seldom immoral; but preëminently, because of their ancestry, they are proud. To some extent their word can be depended upon. They have common sense and are generous to a fault, yet their prejudices will sway them at times to unreasonable ends. They are improvident and wasteful, yet understand basic principles of business because of actual experience on their farms, which has taught them that they who do not produce cannot eat. It is easy for them to understand that a business may fail, because many times their crops have failed.

---

[1] Industrial Engr., Fulton Bag and Cotton Mills. Mem. Am.Soc.M.E.

For presentation at the Spring Meeting, Atlanta, Ga., May 8 to 11, 1922, of The American Society of Mechanical Engineers. Copies may be obtained gratis upon request. All papers subject to revision.

They are of a mechanical turn of mind because of the necessity through generations of shoeing their own horses, sharpening their plows, and doing carpentry work around their own homes and those of their neighbors.

When properly approached and when they are not distrustful of their leaders, they are easy to stimulate. From the time when their mode of life dated back to the period when they felt a certain aristocracy due to slavery surroundings, following through to the present day, they developed a sort of cult, and one must understand not only their present conditions, but also the conditions generations back to comprehend fully their frame of mind and overcome their strong prejudices. Their lack of training of hand and mind makes them difficult at first as factory workers, but their knowledge of the English language makes them, *when trained*, a group of the most satisfactory and able artisans.

Every point of leadership must be exerted to encourage the untrained and unlettered worker to exercise the proper effort for accomplishment. Response is not quick, but when once trained, he develops skill and ability, which added to his native *stability*, enables him to outclass in many cases the workers of other sections of the country. Manufacturers of the South have never understood that pride in artisanship is one of the prime moving forces of the southern worker. Moreover his home training has developed his respect for authority; he has lived in a patriarchy, in which the whole family follow the laws laid down by the father.

Eastern Immigrant Labor

When, then, the Southerner comes to work in a factory, he already has that respect for authority which is lacking in the immigrant worker who has come to America only recently; searching, expecting, and demanding freedom from every American institution, national and local, civic and commercial. The newcomer ignores the voices of his parents who have not yet learned our language and our customs, and he totally misunderstands the symbolism of the Statue of Liberty.

Foreign workers in New York, Boston, or Philadelphia, make of the factory a veritable tower of Babel, speaking various languages, unimpressed with the fundamental principle that they who would eat must work, failing to realize that the "tools belong to the hands that can wield them." They cannot be made to see that production is the source of all wealth and that buildings and equipment are of no avail unless properly organized to produce. They cannot be made to understand the parallel between the idle farm and an unproductive factory. Deceived at times by unscrupulous management, they are skeptical and distrusting, so that a satisfactory understanding with them is difficult. They are suspicious of authority, and are continually looking for injustices. Such a frame of mind constantly aggravates actual conditions. The result is an unstable working force, difficult to control. There are continual demands of unreasonable individuals; there are high training costs brought about largely by lack of understanding of the instructions given by English-speaking foremen to the many-languaged workers.

Middle-Western Workers

In St. Louis and New Orleans we find conditions which make for better factory control as there is a stability which is due to the predominance of German and French elements. These people have been in these sections of the country for more than a generation. They have learned confidence in the constituted authority of the Government and therefore in the constituted authority of organization. They can speak the language, and are more energetic and better educated and more intelligent than the southern worker. They take training quickly in particular trades, yet their stickability is somewhat less than that of the Southerner.

The control and operation of plants in widely separated sections of the country present, then, problems of management that involve not only the differences of the men in control, but also present the differences of the individuals and the characteristics that make up the *working force*.

When we were training an army we had discipline born of military necessity. The rapidity of the training depended on the ability to discipline the soldier regardless of his type, or the locality of the training camp, and on enforced uniform methods.

If uniform results are to be secured in factory organizations, certain well-defined methods of control must be practiced. Not having the absolute power of the army, our discipline must be built on leadership, fair play, and the necessities of the plant as a whole. All workers must be judged by their performance, as shown by fair, equitable, and scientifically set standards.

When the Gantt methods began years ago to point the questioning finger at our many organizations throughout the United States, they inspired the campaign for facts, which facts every honest factory manager had to answer sooner or later. The eternal question of why the fall-down, if honestly answered, placed the responsibility upon the managerial control of the plant, and in most all cases showed that the worker was the scapegoat.

Good Management Essential

The answer always lay in planning, scheduling, disciplining, and training. The most important of these elements of good management as we view the many kinds of people in the various parts of the country, is training. It is comparatively easy to plan the work in New York or to schedule a factory's operations in San Francisco, but the accomplishment of such plans and the carrying-out of such schedules is absolutely dependent upon the training, discipline, and control of the organization wherever located.

During the most trying period that the productive forces of industry have ever passed through, our experience has proved that equal results *can* be secured regardless of the locality of the factory or the type of the worker. We further know that such results only come with the proper training and that such training is only possible when all favoritism is eliminated from an organization and well defined principles of discipline are insisted upon among our superintendents.

The South needs training schools to teach all arts. Having been raised through the generations to do things in a crude manner, no artisanship has been taught to the mass. The South needs leaders in the management of every industry. Specific and scientific methods of training and scientific methods of carrying on operations must be developed. The worker cannot train himself—he needs help—he needs instruction, and must have it.

Industrial leaders must be furnished by our technical schools. General education must be made available for the majority, so that the South may take its just place in the industrial world.

American Labor as Viewed by a British Business Man

B. Seebohm Rowntree, a well-known business man and a director of the Industrial Relations Department of the British Munitions Bureau during the war, is of the impression that on the whole an unskilled man emigrating to American today improves his condition. If he is a Britisher his real wages in the new country may not be better than in the old country, but he has a better chance of promotion. An immigrant from Eastern Europe receives more money immediately, and in addition to that has a chance of progress. The skilled worker in America is decidedly better off than a man in similar position in England.

There is more "push," youthful enthusiasm, willingness to take chances in American business than the author found in England. Hand in hand with this goes, however, as he points out, the fact that the American employer is on the whole a better administrator than the English one. He is more alert, more critical of his methods, and quicker to adopt improvements.

The author was particularly impressed by the excellent research work which was being carried on in America, and, as an example, he cites the case of the laboratories of the National Electric Light Association in Cleveland, about which he says that as he came away he felt that no country that is not determined to make the widest possible use of science can long hope to remain in competition with America.

As regards the situation in the labor organizations, the author is a good deal less enthusiastic. He is inclined, however, to blame the employers, who he claims are adopting the same attitude toward the unions as the British employers did 30 or 40 years ago, and, in his opinion, will have to pay for their mistake by years of labor unrest.—*The Century Magazine*, April, 1922, pp. 944–949.

SURVEY OF ENGINEERING PROGRESS

A Review of Attainment in Mechanical Engineering and Related Fields

The Still Engine

THE Still engine which was first described in a paper by Frank B. Ackland before the Royal Society of Arts in May, 1919, is a combination of internal-combustion engine of the high-compression type and a steam engine. It is being developed by the Still Engine Co., London, and its licensee, Scott's Shipbuilding and Engineering Co., Greenock.

Extensive tests have been carried out on this engine—in particular, those lately conducted by Capt. H. Riall Sankey, former president of the Institution of Mechanical Engineers. Besides its main feature of combining an internal-combustion engine and steam engine in which steam generation is a by-product of the main engine operation, in the Still engine steam is utilized for cooling the piston, and as a certain amount of superheat is added to the steam during that process, the efficiency of the steam cycle is thereby improved. Also, by burning oil in the regenerator, steam may be used for starting and maneuvering.

The experimental engine described in the present article, known as the Scott-Still engine, was built to cover a range of power varying from about 700 to 7000 b.hp., and has cylinders 22 in. in diameter and 36 in. stroke. Such an engine running at a speed of 120 r.p.m. was estimated to give a normal brake horsepower of 350 in one cylinder and an overload of about 400 b.hp.

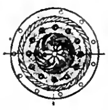

Fig. 1 Combustion-Cylinder Ribbing, Still Engine

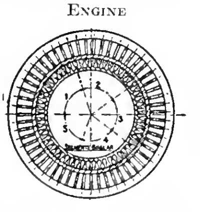

Fig. 2 Piston-Head Ribbing, Still Engine

The crankshaft and the bed plate were designed so as to be suitable for six cylinders of this size in line. As however, it was considered desirable to work the experimental engine on the compound principle on its steam side, so that its working condition might approximate as closely as possible those which will obtain in a multi-cylinder engine on board ship, a small independent single-acting high-pressure steam engine with a cylinder of 14 in. diameter and 22 in. stroke was also constructed and coupled direct to the main-engine crankshaft. The cranks of the two cylinders are arranged at the same angle relative to the dead centers so that the pistons move up and down together. By this arrangement the steam side of the main or combustion cylinder which forms the low-pressure stage is ready to take steam just as the high-pressure cylinder begins to exhaust. The steam side of the main cylinder is 180 deg. of crank angle behind the oil side, so that the engine is double-acting in its operation with this limitation, however, that the power developed on the steam side is considerably less than that developed on the oil side.

Cylinders are provided with liners, which, in this case, are only $^5/_8$ in. thick in the body (see Fig. 1).

The main idea underlying the design of the Still engine liner is the reduction of the temperature differences and consequent heat stresses between its inner and outer walls to the lowest possible minimum, and the provision of ample surface for the rapid transfer of heat to the jacket water. The whole combustion load is taken by the breech end of the liner, and transmitted through the conical joint to the large steel bolts. There is no cylinder cover on the engine in the sense in which a cover is understood in oil-engine practice.

The steam and the exhaust valves, of which there are two and four, respectively, of simple piston type, are carried well on to the cover head to reduce the steam clearance volume to a minimum, and are directly connected to their operators bolted on to the cover flange.

In this connection it should be understood that the combustion and steam cylinders are rarely component parts of the whole with a common piston.

The piston is made in two parts. The skirt calls for no remark, but the head is spirally ribbed internally as shown in Fig. 2, to guide the flow of steam over the crown in as long a path as is reasonably possible. At the same time this formation provides the piston with some degree of flexibility and allows it to adjust itself to temperature conditions without danger of fracturing the ribs. The piston rod is deeply embedded in the piston head with spigot and flange, and the attachment of the two is made by studs and nuts. The piston head is pierced by six holes for the guidance of the steam to the piston head, and is enlarged in diameter at this part to maintain its strength. These holes, acting in conjunction with the steam valves and ports, convey the steam during the admission period into the cylinder by way of the ribbed space on the under side of the piston head, heating the steam and cooling the head, to the manifest advantage of both.

The piston-rod crosshead is of special design. It is well known that the crosshead bearings of most types of Diesel engines are very heavily loaded and frequently give trouble from that cause. In the Still engine, although the load is naturally reduced because of the cycle, the crosshead has been designed to still further reduce the load, and to insure cool and easy working under all conditions. The design adopted admits of the length and diameter of the pin on its underside being available for the downward combustion load. On its upper side the pin is secured to a saddle, which takes the half-bearings for the upward steam load. This saddle is bossed, and provides for the attachment of the complete crosshead to the piston-rod by cotter. In this construction the top and bottom bushes work on different bearing diameters, but these being concentric, no real objection can be taken to the design on this account, and in practice the whole bearing works satisfactorily.

As regards the valve gear when the engine is running, the only valves in operation are the fuel-injection valve on the combustion side and the steam-exhaust valve on the steam side. The former is worked automatically by the fuel,-injection pressure and the latter by oil under pressure. The fuel-injection pump has a solid plunger $1^1/_4$ in. in diameter with a stroke $^1/_3$ in. fitted to the pump barrel without backing. The timing of the fuel injection is fixed by the fuel cam and the period of injection by a spill valve. (The interesting operation of this spill valve is described in the original article.)

The oil-pressure system for operating the steam inlet and exhaust valves is such as to eliminate all layshafts, eccentrics and similar mechanism. Its operation is shown by Figs. 3 and 4 and is, as follows: A simple plunger type of pump worked from the main shaft supplies oil at a pressure of from 350 lb. to 450 lb. per sq. in. to the valves to be operated. The oil passes from the pump through a distributor worked by spiral gearing from the main shaft. Separate distributors are provided for the steam inlet and exhaust valves. These are shown in Fig. 3 at *A* and *B*, and sectionally in *C* and *D*, Fig. 4. The ports are so arranged in the cylinder and piston that once per revolution they register and give an impulse to the column of oil between them and the valves, thus opening the latter. An operator directly connected to each valve is interposed between this volume of oil and the valve, to receive and transmit the impulse. It is under a constant pressure of oil direct from the pump on its upper side, and is subject to an intermittent impulse pressure load on its under side. As soon as the impulse load is released the constant pressure closes the valve. The operator on its under side is of greater area than on its upper side, and this difference gives the upward load required to open the

valve when the ports which are used for operating the steam inlet valves to give a late cut-off when starting up the engine. This exhaust and starting distributor is fitted with a shuttle valve which is set by oil pressure for ahead and astern running. The steam inlet, on the other hand, is provided with a slipping arrangement on the plug coupling for this purpose.

The oil-pressure system is used also for starting up the engine and for maneuvering. During these processes the oil-pressure supply is obtained from an independently driven stand-by pump. The regenerator is a small boiler of 150 lb. working pressure, 5 ft. 6 in. in diameter and with 300 sq. ft. of surface.

In starting from cold the burner under the regenerator is lighted and steam is raised as in an ordinary boiler. The engine may be kept running on steam alone for any desired length of time, or fuel may be cut in as soon as it becomes warmed up, and the engine brought up to the required speed. The cutting of the fuel is accomplished simply and easily by means of the governor or hand-lever control acting on the spill valve above referred to.

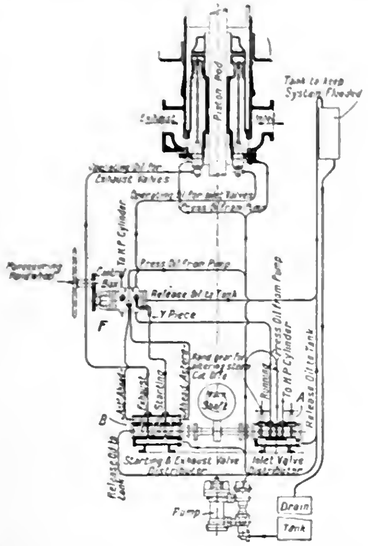

Fig. 3 Diagram of Oil Valve-Control System

Tests were made to determine the weight of steam generated in the experimental unit. The quantity of steam generated from waste heat by the single cylinder is 800 lb. per hr. at 120 lb. pressure per sq. in. when the combustion cylinder is working with about 80 lb. mean pressure equal to a normal load of about 340 b.hp. It increases as the load is increased and falls away as the load is reduced, until at about 35 lb. mean pressure in the combustion cylinder just sufficient heat is being recovered to equalize the radiation losses.

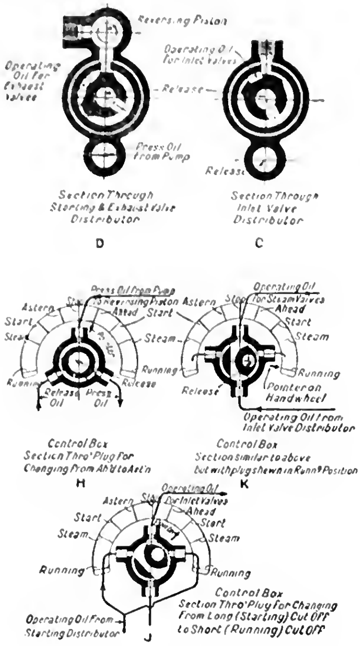

Fig. 4 Diagram of Oil Distributors

The preparation of power obtained from the steam side amounts to about 12 per cent of the total horsepower at full normal load. This applies, however, only to the single-cylinder engine and from 15 to 20 per cent are expected from the multi-cylinder engine. Extremely interesting data of tests are reported in the original article which cannot be abstracted owing to lack of space. (*The Engineer*, vol. 133, nos. 3451 and 3452, Feb. 17 and 24, 1922, pp. 180–182 and 204–207, 20 figs., *deA*)

The Manufacture of Iron and Steel Tubing and Pipe

By EWALD ROEBER

All iron and steel tubing and pipe may be divided into two main classes; viz., A, those with a longitudinal seam, and B, those without a longitudinal seam (seamless tubing).

There are quite a number of processes for making tubing and pipe in each of the two classes. The author considers the various processes, with the exception of cast pipe. Welded pipe is made now practically exclusively out of mild steel and no longer of wrought iron. The most important processes (*Verfahren*) for the manufacture of welded pipe are as follows:

I Butt welding by drawing
II Lap welding by rolling
III Water-gas welding
IV Autogenous gas welding
V Electric welding.

Seamless tubing is made practically exclusively from ingot steel by the following main processes:

VI Cross-rolling and rolling in pilgrim rolls (Mannesmann process)
VIIa Piercing-press and draw-press process (Ehrhardt process)
VIIb Piercing press and draw press for larger sizes
VIII Cross-roll piercing and continuous rolling
IXa Cross-roll (disk) piercing (Stiefel process) and duo-rolls (Swedish rolls)
IXb Press pointing, press piercing and duo rolling
IXc Press piercing (Ehrhardt) and duo rolling
IXd Cross-roll piercing and duo rolling.

In addition to these the following process is used for the manufacture of tubes of large diameter and comparatively short length:

X Press piercing, press drawing and rolling on special rolls.

The processes of manufacture of butt-welded pipe by drawing and lap-welded pipe by rolling (I and II) are the oldest by which pipe has been manufactured.

The material used in making welded pipe comes in the form of skelp, of which the length, width, and thickness correspond to the length, diameter, and wall thickness of the finished pipe. For the manufacture of seamless tubing, the material comes in the form of solid billets of round or rectangular section, those for the smaller sizes being rolled previous to piercing.

In process I of welded-pipe manufacture the skelp goes first to the cold shears where it is beveled on the edges and, to a certain extent, shaped. From the shears it goes to a furnace heated by coal or producer gas and is there brought to a welding heat. The white-hot skelp is gripped by tongs and drawn through a bell-shaped die in which it is simultaneously bent to proper pipe shape and butt-welded. First, before the skelp enters into the bell die the edges are subjected to a blast of compressed air, the purpose of which is to clean them of slag and raise the temperature so as to facilitate the welding. With this arrangement it becomes possible to complete the welding of pipe in one draw, i.e., in one heat. The welded pipes then go to sizing rolls where they are brought to proper dimensions; from these they go to straightening rolls, the purpose of which is indicated by the name, and thus, final shaping of ends and inspection.

In process II, lap-welded pipe, the preheated skelp goes to special rolls where its edges are beveled, and then it is passed on the same heat through the bell die and shaped into a tube. This tube with the edges apart is sent again, while still warm, to the heating furnace where its temperature is raised to welding heat. From the furnace the tube goes to the welding rolls where the actual welding is done. The larger sizes of pipe are bent to tubular shape not in bell dies but in plate-bending machines, from which they likewise go to the reheating furnaces.

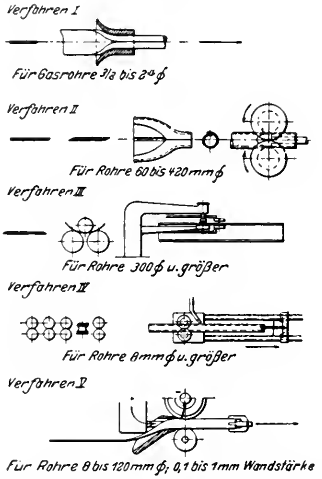

Fig. 1 Various Processes for the Manufacture of Welded Pipe
(For particulars see text.)

To some extent pipe may be made complete in one pass in the weld-heating furnace. As a rule, however, from two to three reheats are necessary. The welding rolls consist of a pair of grooved rolls in which the tubes are rolled over a mandrel which is supported by a long, strong bar. Lap-welded tubes after welding have also to be passed through sizing rolls, straightening rolls, etc., like butt-welded pipe.

In the water-gas welding process of pipe manufacture (process III) only the edges of the skelp are brought to welding heat. The skelp is beveled in beveling machines and then bent to pipe shape on plate-bending machines, this bending being carried out either in the cold or in the hot state, depending on the diameter of the pipe and its wall thickness. The pipe is then brought, spot after spot, to welding heat by a water-gas torch inside and out and welded over an anvil by steam, compressed air, or hand hammer. In some instances hydraulic pressure is employed instead of hammering. This kind of pipe comes out from the welding smooth and even. In processes IV and V (autogenous welding and electric welding), as in the previous process, only the welding edges are heated; in process IV, acetylene or hydrogen are used practically exclusively.

For producing seamless tubing on the Mannesmann cross-rolls and pilgrim rolls (process VI), it is necessary to start with solid round billets. These are preheated in a coal- or producer-gas-fired furnace, pierced on the cross-rolls and drawn out into long tubes on the pilgrim roll stand. In the case of pipes of more than 300 mm. (11.8 in.) diameter it has been so far necessary to put the billet through the cross-rolls twice, although there are new installations in which these tubes can be pierced in one pass. The tubes from the pilgrim roll stand are usually brought to the right size on draw benches or sizing rolls.

In process VIIa, press piercing and press drawing (cupping), square-section billets are used. These billets are preheated in a furnace and then pierced in a press in such a manner, however, that the hollow billet retains a solid bottom. The hollow block is then (on its original heat) put into a long horizontal press and mandrel attached to the press plunger is fixed into the billet which is then forced under pressure through a series of consecutively placed dies, and thus drawn out into a tube. Process VIIb is substantially the same as VIIa, only instead of having the dies in the draw press located consecutively one after another, the billet with the mandrel inside is passed through a single die, then drawn back and the die replaced by a smaller size, after which the process is repeated.

The cross-roll piercing and continuous rolling process (VIII) at the outset is like process VI with solid round billets, which are pierced in the cross-roll stand and on the same heat put over a long mandrel and sent through a set of consecutively located pairs of rolls, of which there may be seven. In processes IXa to IXd, inclusive, various special devices are used for piercing a solid block, but the duo rolls are used in all of them for rolling. For the Stiefel process (IXa) and for process IXd round billets are used, while for processes IXb and IXc square-section billets are preferred. The Stiefel stand is essentially similar to the Mannesmann stand, but is used for producing thinner-walled tubing than the Mannesmann.

In the piercing press of process IXb a mandrel is pushed through to the middle of the billet from both sides after which the billet thus pointed is put on a piercing press and there pierced entirely by a bigger-size mandrel. In the piercing-press operation in process IXc the square-section billets are pierced through by a single mandrel exactly as in processes VIIa and VIIb, but the hole goes clear through and no solid bottom in the billet is left. The hollow billet from the presses in all of these four processes goes to the duo rolls on its own heat. The duo rolls consist of several sets on which the hollow billet is rolled into a tube over a plug. The plug lays here in a groove between the two rolls and is supported by a bar located behind the rolls.

The stand in this roll is from 1.2 to 1.8 m. (47 to 70 in.) wide and contains a number of flat rolls placed side by side.

For some time now the practice has been to send the pipe coming from the duo rolls through finishing rolls to give it a smooth surface and possibly to size up closer the wall thickness. From the finishing rolls the pipe goes through sizing rolls, then straightening rolls, and after passing through anneal, on to inspection. Process X is the well-known Ehrhardt process for making large seamless hollow bodies. Billets are hollowed out in big presses similar in character to those employed in processes VIIa and VIIb, i.e., with solid bottoms (cupping process), and then further drawn in big cupping presses, after which the bottom of the cup is cut off and the hollow billet rolled in a special mill in which there are rolls inside and outside of the billet.

Figs. 1 and 2 show diagrammatically the essential features of the various processes (*Verfahren*) of manufacturing welded and seamless iron and steel tubing and pipe.

In Germany butt-welded pipe is made in sizes of up to 60 mm. (2.36 in.) in diameter and abroad in sizes up to 3 in. The wall thickness varies from 2.5 (0.1 in.) to 4.25 (0.16 in.) mm. for gas pipe, and 2.75 (0.108 in.) to 5 (0.19 in.) mm. for steam pipe. Pipe by this process is made in lengths of 5 to 6 m. (16 to 20 ft.). Lap-welded pipe by process II is not made by welding rolls in sizes less than 60 mm. (2.36 in.) outside diameter. The usual range for such pipe is 60 to 420 mm. (2.3 to 16.5 in.) although abroad such pipe is made in sizes up to 520 mm. (20.4 in.). With this process there is no trouble in making pipe of standard thicknesses for boiler use, and pipes with thinner walls can be also made without trouble. Such pipe is made in lengths up to 7$^1/_2$ m. (25 ft.).

Pipe welded by water gas (process III) is made with diameters

starting from 300 mm. (11.8 in.) and can be made in thicknesses up to 90 mm. (3.5 in.) and lengths up to 8 m. (26 ft.). Gas- (acetylene or hydrogen) welded pipe (process IV) can be made with diameters from 8 mm. (0.3 in.) up to the largest desirable, and in wall thicknesses from 0.5 mm. up to 10 mm. (0.019 up to 0.39 in.). Pipe in sizes from 8 to about 120 mm. in diameter (0.314 to 4.72 in.) and in length up to 9 m. (26 ft.) is made on special automatic machines. Larger sizes of pipe are welded by hand, and in such cases the length of the pipe is practically unlimited. The range of electrically welded pipe is the same as that of gas pipe. It must be noted, however, that its development has not progressed as far as that of the other methods in Germany, and it is only quite recently that methods have become known there for welding such pipe in wall thicknesses under 1 mm. (0.039 in.).

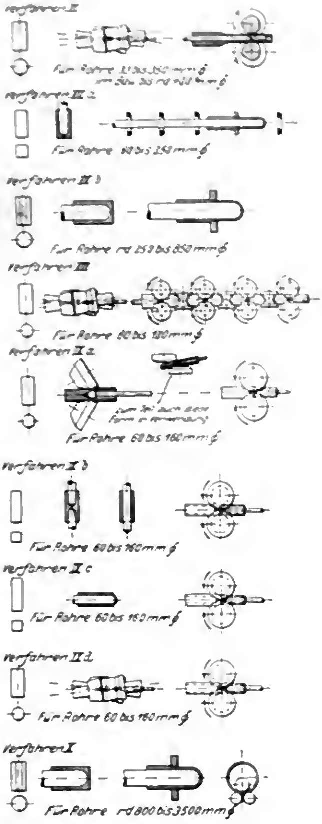

Fig. 2 Various Processes for the Manufacture of Seamless Tubing
(For particulars see text.)

As regards seamless tubing, the Mannesmann cross-roll and pilgrim-roll process (VI) gives pipe from 35 to about 350 mm. (1.3 to 15.7 in.) outside diameter with wall thicknesses of boiler-tube standard as a minimum, i.e., 2¼ to 9 mm. (0.08 to 0.35 in.). This kind of tubing is made chiefly in double lengths of 12 to 15 m. (0.47 to 0.59 in.). Longer tubing, however, can be made by this process.

By the Ehrhardt cupping process (VIIa) the smallest tubes made are 60 mm. outside diameter (2.36 in.) and the largest up to about 250 mm. (10 in.), but pipe with wall thicknesses less than 3 mm. (0.12 in.) have not been made here. Process VIIb is a very modern development. By it pipe is already made with outside diameters up to 850 mm. (33.5 in.) and lengths up to 5½ m. (18 ft.) with wall thicknesses of about 150 mm. (6 in.). Process VIII permits making pipe from 60 mm. to 120 mm. (2.36 to 4.72 in.) diameter and processes IXa to IXd, inclusive, pipe from 60 to 160 mm. (2.36 to 6.3 in.). In all of these processes the wall thicknesses range from about 3 mm. up to 15 mm. (0.11 to 0.59 in.), while the lengths vary from 7 m. to, say, 10 m. (23 to 33 ft.). Process X permits the making of tubular bodies from 800 mm. to 3500 mm. (31.4 to 138 in.) in diameter with wall thicknesses ranging from 10 to about 150 mm. (0.39 to 6 in.). The original article gives a diagram showing these various dimensions.

A comparison of the various processes for the manufacture of seamless tubing shows that for tubing in excess of 160 mm. (6.3 in.) in diameter and in lengths up to 6 m. (20 ft.) the Mannesmann process (VI) and processes VIIa and VIIb may be used, while for lengths in excess of 6 m. (20 ft.) the Mannesmann process alone is available. Tubing with diameters smaller than 60 mm. (2.36 in.) likewise tubing with wall thickness of less than 3 mm. (0.118 in.) have to be finished on hot or cold draw benches. (*Stahl und Eisen*, vol. 42, no. 7, Feb. 16, 1922, pp. 253 to 258, 5 figs., *d*A)

Short Abstracts of the Month

AIR ENGINEERING (See also Internal-Combustion Engines)

BUREAU OF STANDARDS (See Varia)

FUELS AND FIRING

Anthracite Briquetting in Canada

Briquetting Anthracite Fines with Crude-Oil Residuum. Description of the briquetting plant of the Nukol Fuel Company, located at Port Stanley, a few miles from London, Ont., Canada.

The first step in briquetting is to free the raw coal of excessive moisture, which must not exceed about 2 per cent in the final product. In this case this is done by a drier of the single-shell rotating type, 6 ft. in diameter and 40 ft. long. The receiving end projects into a Dutch-oven type of furnace, located directly beneath the wet-coal bin. The coal is delivered to the drier from the bin in a measured flow by means of an apron conveyor and a cast-iron chute passing through the roof of the furnace. The flow of coal is accurately controlled by means of an adjustable gate which permits the regulation of the moisture content. The coal passes through the drier in contact with the hot gases, and when dry is carried away by means of a spiral conveyor and bucket elevator into a bin at the top of the building. Beneath this bin is a pug mill or paddle mixer. The binder is carefully measured in correct proportion to the coal by means of a needle valve, is also introduced by this point. The matter of proportioning is very important. Too little binder results in a weak briquet that will disintegrate on subsequent handling, and too much binder in a soggy briquet produced at an excessive cost. The stirring action of the paddle mixer gives a preliminary mixing to the materials preparatory to fluxing, which is the next step in the operation.

The fluxer is a vertical cylindrical steel tank 40 in. diameter and 6 ft. deep, mounted on a cast-iron base. A shaft within this container carries a series of radial arms and rotates at a uniform speed. Stationary arms attached to the inner surface of the tank project toward the center. The partly mixed material is dropped into the fluxer from the paddle mixer. Here the ingredients are further mixed, or, as it is termed, fluxed, in the presence of steam admitted through openings in the bottom of the tank. This serves to moisten the mixture, or flux, as it is now called, and gives it a peculiar plasticity that facilitates the final mixing, or mastication. The flux is delivered directly into the masticator in a continuous stream, an adjustable gate regulating the flow at a rate synchronized with the delivery of the material into the fluxer.

The next and most important step in the operation of briquet manufacture is the mastication of the flux. The masticator is a ponderous Chilean mill, or *arrastre*. It consists of a heavy cast-iron bed securely bolted to a massive concrete foundation, two A-shaped standards mounted on the bed carrying the steel framework that supports the drive gearing and two huge cast-iron rolls, each weighing several tons, arranged to chase around the bed at eighteen turns per minute. The flux is fed in at the outer edge of

the bed and is gradually moved over by a series of adjustable plows to the center, where it is discharged.

Meanwhile the heavy rolls repeatedly passing over the fluxed material grind and masticate it to such an extent that the coal and binder are intimately mixed. In fact, the binder is literally ground into the coal, and the material has been changed into a practically homogeneous mass.

Under the masticator is a conveying device similar in design to the paddle mixer. This receives the masticated flux, reduces any caking, and delivers the material to a bucket elevator that carries it to the press, where the briquets are formed under a pressure of 3000 to 4000 lb. per sq. in.

Dropping from the press, the briquet fall directly into a bucket elevator which carries them to a rotating cylindrical screen. The peculiar shape and arrangement of the molds cause a small quantity of material to adhere to each briquet in the shape of a rough edge or fin. The tumbling action of the screen removes this material, and also eliminates occasional weak or imperfect briquets. This waste is returned directly to the masticator to be reworked.

Material to be briquetted passes through the press in a heated state, usually at 125 to 140 deg. fahr., and though the briquets at this temperature are strong enough to withstand the action of the elevator and screen, they are still so plastic that they would crush under the imposed weight of piling in a car or bin. It is necessary therefore that they be thoroughly cooled.

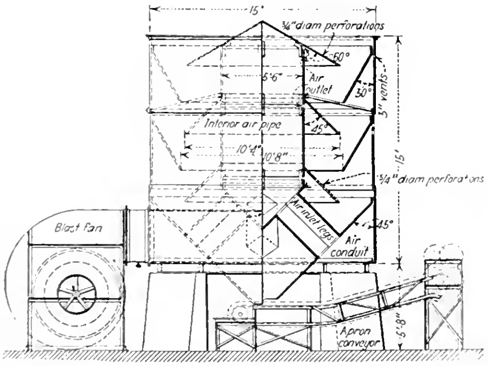

Fig. 1 Device for Cooling and Hardening Briquets

Instead of the usual water cooling of the briquets, air cooling is used. The air cooler, Fig. 1, is a vertical steel tank 15 ft. in diameter and 15 ft. deep, mounted on a concrete base. Extending through the center of the tank is an interior tower, or pipe of large diameter, which serves to conduct and distribute the cooling air.

Forming the top of the inner pipe and extending beyond its periphery, is a cone of projected area about half the area of the main tank. In order to give the briquets an inclined descent, and at the same time break up the mass into sections of small area, keeping the individual briquets in motion relatively to each other, a series of plates, or cones, are provided, so arranged that the briquets pass over first one and then the other as they move downward through the apparatus. These deflecting plates are placed alternately on the interior pipe and the exterior casing.

A funnel-shaped plate, attached to the exterior casing about 3 ft. from its lower edge and converging in the center with an opening for discharging the briquets, forms the bottom of the tank. The interior pipe is supported from this plate by four hollow legs. The annular space beneath the bottom plate is sealed and serves as a conduit for the air.

The required volume of air for cooling is supplied by a large fan connected to this annular conduit. From this chamber the air goes through the hollow legs into the interior pipe. A series of gaps, or openings, allow it to escape at points beneath the interior deflecting plates. These are perforated with many small holes, so that the air passes directly through the mass of briquets, absorbing their heat and finally escaping through vents in the outer casing to the atmosphere. The fan develops a pressure of about 1 oz. per sq. in. and maintains a constant circulation of air throughout the entire tank.

The briquets are received at the center of the cone top. In operation the tank is kept full, the discharge being controlled in accord with the input. The tank will hold fifteen tons, or an hour's output of the plant, and the briquets will thus be subjected to the cooling action of the air for this same period.

It is said that conditions in the coal trade in middle-eastern Canada are such as to favor the development of the anthracite briquet industry. (*Coal Age*, vol. 21, no. 10, Mar. 9, 1922, pp. 403–406, 2 figs., *d*)

HEATING AND VENTILATION

Mechanical Utilization of Energy Content in Steam at very Low Pressures as a Means of Improvement of Efficiency of Central-Heating Stations, Andre Nessi. The author discusses various types of heating such as hot-water and hot-air, and the methods of utilizing the mechanical energy content in the steam at very low pressures, which is a by-product of these installations. The article is essentially descriptive, and therefore not suitable for abstracting, notwithstanding its interest. The conclusion of the author is that in large heating units it is advisable to install machinery for utilizing the residue energy in the steam, providing, however, the operation of such machinery is continuous and automatic. The machinery can be so designed, as he shows, as not to entail any extra demand on the personnel operating the heating plant. (*Bulletin de la Société d'Encouragement pour l'Industrie Nationale*, vol. 133, no. 10, Dec., 1921, pp. 1322–1363, 31 figs., *dd*)

Reversed Heat Engine for Heating Purposes

The Reversed Heat Engine as a Means of Heating Buildings, P. B. Morley. In 1852 Lord Kelvin pointed out that in heating a building by the burning of oil one may employ an indirect process comprising a heat engine and "warming machine" driven by the engine, by means of which the heat delivered to the building might be much greater than heat of combustion of the coal consumed. In other words, the system, considered merely from the point of view of coal consumption, would work at an efficiency better than 100 per cent. The author states that he is not aware that this proposal has ever been put into practice and discusses the theoretical possibilities and the nature of the difficulties to be overcome in its application.

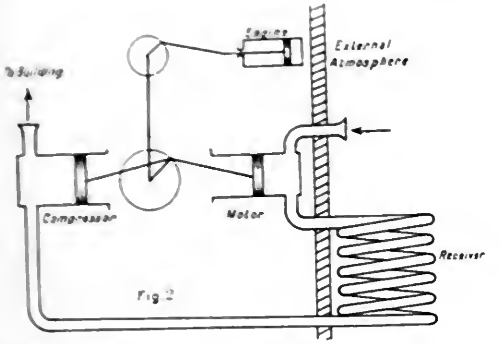
It being desired to pass into a building a supply of heated air, it is convenient that the air to be heated be itself the working substance in a reversed heat engine or warming machine. The machine would have two cylinders, which Lord Kelvin called "ingress" and "egress" cylinders. We shall refer to them as "motor" and "compressor," since the air does work in the former while work is spent on compressing in the latter. The cycle of operations would be as follows: Air from the external atmosphere would be admitted into the motor cylinder for part of the stroke, the inlet valve would then close and for the remainder of the stroke the air would expand, falling in pressure. The drop in temperature during the expansion would be reduced as much as possible by making the motor cylinder of highly conducting material with a large surface for heat transmission. On the return stroke the air would be discharged into a receiver, also designed to encourage heat transmission and having its external surface exposed to the external atmosphere or, better still, to a stream of water. The intention, in fact, is to obtain as nearly as possible isothermal expansion and to obtain in the receiver air at a pressure below that of the atmosphere and as little below the outside air temperature as possible. The receiver might well take the form of a coil of pipes as shown diagrammatically in Fig. 2. As the object is to obtain warm air finally, the warmer the air is in the receiver the better, provided the receiver temperature is not obtained by the expenditure of fuel or energy.

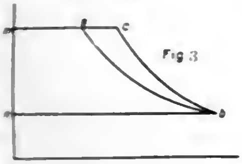
The low-pressure air would then be passed into the compressor cylinder and would be compressed therein till atmospheric pressure was again reached, the operation this time being adiabatic. The temperature at the end of compression would then be a maximum, and this heated air would finally be delivered into the building.

Fig. 2 shows diagrammatically the arrangement of the apparatus. The work spent on the air in the compressor would exceed the work done by it in the motor cylinder, the difference being supplied by an independent engine, water motor or electric motor.

The indicator diagrams for the process would be as shown in Fig. 3 or Fig. 4. In Fig. 3 it is assumed that the expansion is isothermal; the motor diagram is *mabn* and that of the compressor *abcm*. Fig. 3 is for the more likely case in which the expansion *ad* is not isothermal, but in which the original temperature is regained in the receiver, the air therefore increasing in volume in the receiver from *nd* to *nb*. The point *b* corresponds to *b* in Fig. 3, and the compressor diagram *abcm* is the same as before.

Lord Kelvin took as an example the heating of air from an external atmospheric temperature of 50 deg. fahr. to a final temperature of 80 deg. fahr. and calculated that by means of an ideal machine 1 lb. of air would be delivered per second with an expenditure of 0.283 hp. for driving purposes. The heat equivalent of this power is 0.2 B.t.u. per sec. The heat required to warm 1 lb. of air from 50 deg. to 80 deg. fahr. is about 7 B.t.u., so that the heat given to the air would be thirty-five times the heat equivalent of the work spent.





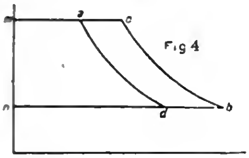


Fig. 2 Diagram of the Reversed Heat Engine

Fig. 3 Indicator Diagram of Reversed Heat Engine under Assumption that Expansion Is Isothermal

Fig. 4 Indicator Diagram of Reversed Heat Engine under Assumption that Expansion Is Not Isothermal

As a means of supplying the driving power, Lord Kelvin contemplated a steam engine capable of converting into work one-tenth of the heat generated by the combustion of coal, so that the effect of the whole combination would be that the heat imparted to the air would be 3.5 times the calorific value of the fuel. A modern steam plant of the best type, has, of course, a much higher overall efficiency than one-tenth, amounting to 16 to 17 per cent of even higher in especially good power stations, and internal-combustion engines have a still higher efficiency. Thus, after allowing for losses of power and heat in the warming machine arising from friction and imperfect heat transference, it would appear probable that, by the method described, useful heating effect in the warming of air could actually be obtained with the expenditure of much less fuel than would be required to obtain the same effect by direct heating, even with the absolute elimination of the losses. Though at first sight this result is paradoxical, further consideration will show that it is in no way in conflict with the laws of thermodynamics nor, of course, therefore, with the law of the conservation of energy. (*The Engineer*, vol. 133, no. 3450, Feb. 10, 1922, pp. 145–146, 3 figs., *tm*. In this connection attention may be called to the paper presented by A. Altenkirch at the International Congress of Pefrigeration in New York and Chicago, 1913 [Cp. *Eis- und Kaelte-Industrie*, vol. 6, no. 2, August, 1913, pp. 29–34], where an installation based on the same principles of operation was described and it was stated that several such units have been actually installed and put in operation on the continent of Europe.)

HYDRAULIC ENGINEERING (See Machine Design and Parts)

INTERNAL-COMBUSTION ENGINES

Flow of Gas into a Cylinder, A. Johnson. The article here abstracted deals with flow of air into a cylinder of an internal-combustion engine during operation. Under the circumstances adiabatic flow is out of the question and the air flowing into a hot cylinder is likely rather to gain than lose temperature. As a useful compromise it may be assumed that the temperature of the gas does not alter, so that PV is constant.

From a mathematical consideration of the subject the author arrives at the conclusion that, reckoned by weight, the rate at which air enters a cylinder (assuming no change of temperature) is greatest when the pressure inside the cylinder is little more than half the atmospheric pressure, or, to be accurate, that it would be so if the pressure within the cylinder were the same at all points, a condition inconsistent with the motion of the entering air but one which the author is compelled to assume for the purpose of approximate calculation.

From the point of view of the internal-combustion engineer dealing with an engine making many strokes in a second, the question of greatest interest is in what time he may expect his cylinder to fill, or what will be the density of the gas which it contains at the end of a given time.

This is again treated mathematically and the author arrives at the expression:

$$t = \frac{2}{R}\sqrt{\log p_0 - \log p_1}$$

where t is the time of filling the vessel completely; p_1 is the original pressure; p_0 final pressure, or the pressure in the cylinder when completely filled; and R in this case is a constant depending, however, on p_0. The author shows that under certain limiting conditions, expansion from $p = 15$ to $p = 3$ is about the range which permits the gas to flow in a stream of constant area. The remainder of the article, while of considerable interest, is not suitable for abstracting. (*The Automobile Engineer*, vol. 12, no. 160, Feb., 1922, pp. 41–43, 7 figs., *t*)

MACHINE DESIGN AND PARTS

Hydraulic-Power Transmission Gears, H. M. Sabine. In England, variable-speed hydraulic pumps and transmission gears have been found to be suitable for heavy-gun training, steering gears, winches, heavy-machine-tool and textile-machinery drives, rotary furnaces and tube mills, etc. The Williams and Janney gear has been chiefly applied as a transmission gear. The Carey and Hele-Shaw types have so far been chiefly employed as variable-delivery pumps, the latter system having, however, been applied also for transmission gearing. A hydraulic-transmission gear will also act as a clutch or brake.

What is wanted, and what certain of these transmission gears are being developed for, is a variable-speed pump, with a high speed of from 1000 to 1500 r.p.m., or even greater, and capable at this speed of delivering oil up to 1000 to 1500 lb. per sq. in., and about 4000 lb. per sq. in. pressure or more at about a quarter full speed. Overload pressures of 2500 lb. per sq. in. have been maintained already at slow speeds, and are being announced in the advertisements of the Carey and Hele-Shaw pumps and transmission gears. A Carey pump has actually worked at over 4000 lb. per sq. in. oil pressure for two hours on test, and as regards speed, 1000 r.p.m. is by no means too high a speed for certain medium-size pumps of the Carey type.

A great gain in efficiency will naturally ensue with the transmission gear or pump designed to run with air-filled case, owing to the elimination of the stirring losses which increase rapidly as the speed increases and which constitute the chief initial loss in

these machines. The temperature would be lessened, and therefore the oil would not get so thin, consequently the decreased leakage past the pistons and valve faces would result in greater efficiency. Further, the weight of the gear in working order would be less—a great consideration in automobile work—also the speed could be considerably increased.

An outline of some of the possibilities of variable-speed pumps and transmission gears, is followed by mention of some of their limitations. Transmission applications are classified under the following standard cases: (1) constant horsepower, with variable torque and speed; (2) constant torque, with variable horsepower and speed; (3) constant speed, with variable horsepower and torque. When dealing with inquiries from engineering and other manufacturing concerns, the author was frequently surprised at the apparent lack of knowledge regarding horsepower and power transmission. For instance, a firm would ask a quotation for a gear to transmit 10 hp. and to run between 500 and 20 r.p.m. If constant horsepower was required, the torque at 20 r.p.m. would necessitate using an extremely large pump, or alternately, an additional spur or worm reduction gear between the pump and the driven machine. Upon further inquiry, it would often happen that the full horsepower was not required at the slower speed. Again, a firm would ask for a gear to transmit, say, 50 hp. with a 5 to 1 speed range, and omit to give the maximum or minimum speeds, which, of course, would make all the difference in the size of the gear suitable. Many manufacturers seem quite unable to give the maximum and minimum torques together with the corresponding revolutions per minute for the machines they make. Sometimes a full questionnaire would have to be sent to a firm to get it to state particulars correctly.

The author gives a list of particulars required for designing a transmission set, and points out that usually the most important point is the torque range during which constant horsepower is being transmitted.

It is the maximum oil pressure which determines the torque or speed range, and the length of time the machine would be required to work at a maximum torque will determine the size to be employed. (*The Practical Engineer*, vol. 65, no. 1828, Mar. 9, 1922, pp. 151–154, 3 figs., to be continued, *dp*)

MACHINE TOOLS

Worm-Gear Generator

British Worm-Gear Generator. The generator described in the original article is suitable either for the accurate production of single wheels with a fly cutter or for the manufacture of gears on intensive lines by the use of hobs. The machine is of the tangent-feed type, with a special mechanism to impart an added movement to the wheel blank corresponding at the pitch line exactly with the tangential traverse of the cutter. This movement is obtained without the use of change gears, eliminating complicated calculations and difficulties in setting up.

Fig. 5 is a transverse section through the generating mechanism to illustrate the principles of action. The worm *A* which drives the work spindle *B* is supported between bearings on a slide parallel to the slide for the cutter arbor. The driving worm is of exceptional length, and it is possible to rotate the work spindle by an axial movement of the worm, in addition to the regular motion which is obtained by the rotation of the worm shaft. For this purpose the substantial lever segment *C* pivoted on a large vertical pin *D* is provided with radial slots having slide blocks which operate the respective slides.

To obtain the correct relative motion between the cutter slide and the wheel blank, it is then only necessary to make the distance from the center of the pivot for the lever segment to the lower sliding block equal to the pitch-line radius of the driving worm wheel for the work spindle, while the distance from the center of the pivot to the center of the upper sliding block is made equal to the pitch-line radius of the worm wheel to be cut. Further, by the provision of special measuring faces, this setting may be made accurately without difficulty, so that the arrangement for obtaining the correct relative movements between the cutter and the work may be said to represent a distinct advance on the previous methods employed.

The measuring faces for this purpose may be seen at *F*, in Fig. 5, and the method of adjusting simultaneously to the correct position will be clear when it is observed that the cutter slide is mounted on a second transverse slide, which is actuated by means of two guide screws through the medium of a hand-operated shaft and spiral gears. It should also be mentioned that the faces of the measuring blocks are a known distance apart when the pitch line radius of the hob is zero, so that the required distance may always be obtained by subtracting half the pitch diameter of the worm from the fixed distance given by the makers. This enables measuring rods or plug gages to be employed for setting purposes, a method which is calculated to give the greatest degree of accuracy with an unskilled or semi-skilled operator.

A simple form of gage is also fitted for setting fly cutters, the gage being shown above the cutter in Fig. 5. Briefly, it consists of a small bracket located against a suitable face on the slide, and carrying a sliding rod having a collar at the upper end. The length of the rod is then made equal to the distance between the upper face of the bracket and the center, so that the distance from the lower end of gaging point of the rod to the center of the cutter spindle is exactly equal to the distance between the face of the gage block and the collar on the rod. By this means, the correct setting of a fly cutter may be obtained readily by employing a plug gage equal in width to half the outside diameter of the hob represented by the fly cutter. The gage rod may then be clamped in position, so that, although the bracket is removed after setting the cutter, any future settings may be made with the minimum of trouble.

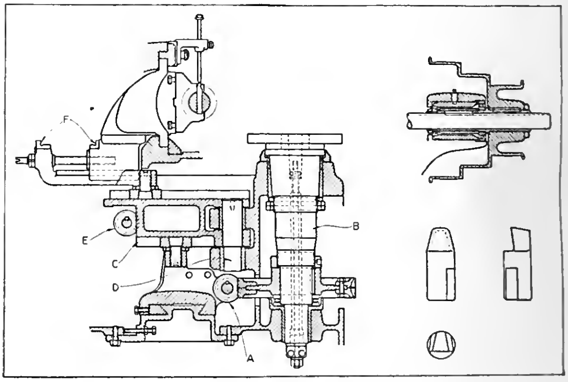

Fig. 5 Worm-Gear Generator

The method of mounting the fly cutter in the arbor also possesses features of interest, and as in the case of other setting operations the object has been to minimize the time required for setting. From the lower right-hand figures in Fig. 5, it may be seen that the cutter is formed out of cylindrical stock, the end being shaped to the normal section of the worm thread, while the shank is cut away at one side, as shown, to simplify the location of the cutter at the correct spiral angle of the arbor. Clamping may then be effected by means of an axial set screw passing through the cutter arbor, and bearing against the flat on the tool. This arrangement has the advantage that the stress on the arbor is central, so that there is no tendency to distortion, as is often the case when cutters or wedges are used for clamping purposes.

Regarding the drive for the tangential feed motion, the worm shaft is extended to a large capstan wheel, and this wheel in turn is frictionally driven from a worm wheel to which power is transmitted through the medium of a feed reverse and change box at the rear of the machine. This feed box provides for twenty feed changes, covering a range of more than 140 to 1. The trip mechanism is of the instantaneous type, the clutch being released in approximately one-eight of a revolution. Notwithstanding the fact that the worm slide which operates the trip mechanism may have a very slow movement. (*Engineering Production*, vol. 4, no. 73, Feb. 23, 1922, pp. 187–188, 4 figs., *d*)

A New British Chucking Machine

An Improved Automatic Chucking Machine. Description of a machine developed in England for work on intricate pieces. The machine, called the "Victor," is intended particularly to be used on locomotive-piston work. It is said also that it will handle all kinds of taper work and bevel-gear work without extra fixtures. In railway shops it may also be used for work on split rings, valve heads, valve followers, bull rings, piston-rod glands, valve-spindle glands, piston-valve covers, main-cylinder covers, eccentric liners, etc.

All automatic changes in this machine are actuated through positive-action friction clutches, and are obtained by the very simple mean of setting dogs on drums immediately under the headstock. The clutches adjust themselves automatically to the load, and require no attention whatever. The main spindle is of large diameter, fitted with ball thrust washers and supported by two substantial phosphor-bronze adjustable bearings. It is arranged to stop automatically before the withdrawal of any cutting tool, and to take up the drive again when the next tool is brought forward for cutting. The turret has four operative faces, and is fitted to the saddle on two coned surfaces. The locating ring is of larger diameter than the turret, the indexing plunger working between adjustable wedges. After locating, the turret is locked to the saddle by a central bolt and locking plate, the turning, locating and locking, all being performed automatically at a high constant speed, the turret and saddle being then securely locked. It is claimed that rigidity, together with absolute alignment, is secured by this arrangement.

Two independent cross-slides are provided, the top slides swivelling to any angle. Both cross-slides have longitudinal and cross automatic movement actuated by the saddle traverse, angular cuts being obtained in like manner. Adjustable micrometer stops are provided for all cross-slide movements, insuring great accuracy. Each cross-slide can be set to have a combined cross, or angular and longitudinal movement, thus enabling a tool to be fed up to its work against a transverse stop and then traversed longitudinally, or vice versa. Each cross-slide can be operated with any face of turret. Provision is made for profiling in conjunction with both cross and longitudinal traverse.

The feed is transmitted from the main spindle through a safety clutch and five-speed gear box to the cam drum shaft, the feed changes being operated by adjustable dogs attached to the change-feed drum. The quick motion of the saddle is taken from the first-motion shaft, which is fitted with a safety clutch, and runs at a constant speed independent of the spindle or feed changes. It is actuated by means of a trip lever, instantaneous in action, the movements from slow to fast or vice versa being operated within $^1/_4$ in. of saddle movement. A conveniently actuated hand motion to saddle and cross-slides is provided, and, by means of a hand lever, all cam gearings can be thrown out of action, leaving only the main spindle operative for chucking purposes. (*The Railway Gazette*, vol. 36, no. 9, Mar. 3, 1922, pp. 351–352, 2 figs., *d*)

PHYSICS

Velocity of Sound in Air and Hydrogen at 0 Deg. Cent. and 1 Atmos. Pressure, E. Grueneisen and E. Merkel. The subject is of considerable interest because velocity of sound appears in equations dealing with the design of steam and internal-combustion engines; in particular, in connection with the subject of critical velocity of flow of gases through nozzles. The authors carried out the measurements in connection with their investigation of velocity of sound in partially dissociated gases, and the present paper covers measurements on dry air free of carbon dioxide, and on pure hydrogen. The method of measurement is of the kind suggested by Thiesen; viz., with a closed resinator. The paper deals chiefly with the methods of measurements and the various precautions for eliminating sources of error. The final value the writers derive is that the velocity of sound in dry air, free of carbon dioxide at 0 deg. cent. and atmospheric pressure, is 331.57 m. per sec., and in pure hydrogen 1260.6 m. per sec. (*Annalen der Physik*, vol. 66, series 4, no. 5, 1921, no. 21, pp. 344–364, 4 figs., *eA*)

POWER PLANTS (See also Steam Engineering)

The Ruths Steam Accumulator

The Ruths Steam Accumulator, G. Schulz. All steam accumulators, of which there are a good many, are designed for the purpose of saving fuel by enabling the boiler to operate at its most economical load without (within certain limits) being affected by the demand at the prime-mover end. Thus, in an electrical plant the boiler would operate at its most economical load no matter whether the electrical load were near its peak or at a minimum. It is said that the Ruths accumulator successfully accomplishes this purpose.

The essential novelty in the Ruths accumulator is not the accumulator vessel itself but its connections: viz., the fact that it is inserted between the boiler room and the steam piping. The accumulator itself, Fig. 6, is merely a large boiler of simple design filled with water to about 90 per cent of its capacity. The steam enters through valves X_1, Y_1 into the distributing manifold Z and passes therefrom through nozzles P. These nozzles act like jet pumps, and their purpose is to produce a rapid and intimate mixture between the steam and the water. The exit of the steam takes place through nozzle F, shaped like a DeLaval nozzle. With this type of nozzle the steam flow is, up to a certain degree, independent of the back pressure. The nozzle permits the passage of only a limited amount of steam, and acts as a kind of safety valve in case of a rupture of a pipe. On one of the front walls of the accumulator is to be found a water level indicator W properly calibrated and intended to be used for maintaining the water level in the accumulator at a predetermined height. In actual practice it was found that it is only seldom necessary to add fresh water. The vessel is well insulated so that, practically, the heat losses therefrom need not be considered.

As stated above there is nothing strikingly new in the construc-

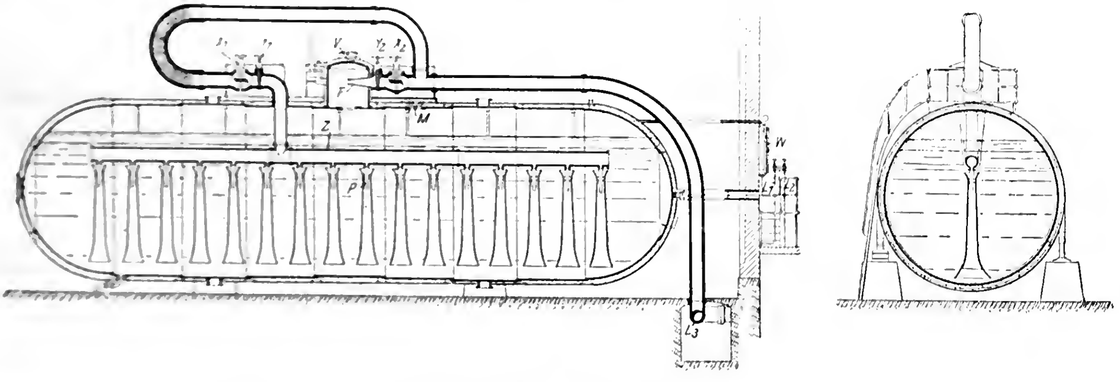

Fig. 6 Ruths Steam Accumulator

tion. What is new is the fact that the accumulator with its great content of water is so connected in the system that pressure variations of several atmospheres may be permitted in the steam piping. Furthermore, the operating range is set chiefly into the region of low pressures, which reduces the initial cost of the installation and increases the ability of the accumulator to handle large amounts of steam.

In the original article is given a curve showing the relation between the steam absorption of an accumulator and the various steam pressures. From this curve it appears that the steam given up by a cubic meter of water at a pressure drop of 1 kg. per sq. cm. varies for different pressures quite materially. For example, at 20 atmos. 5 kg. of steam are given up, but at 3 atmos. more than 20 kg. of steam are given up, which would indicate that the steam-absorption capacity of an accumulator rapidly increases with the lowering of the level pressures.

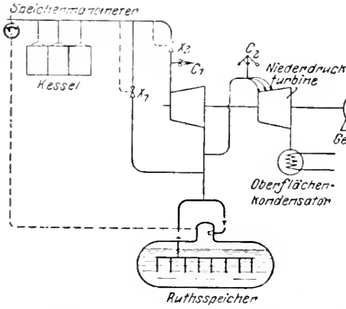

Fig. 7 Diagram of Connections for a Steam-Driven Central Station with a Ruths Accumulator

In the original article, reference is made to tests by Professor Josse showing the great advantage obtained with uniform demand on the boiler as compared to a variable demand, which is of interest as the aim of the Ruths accumulator is to create such a uniform demand. Furthermore, the original article shows several schemes of using the Ruths accumulator, for example, in connection with a central station or an electric plant operating in a blast-furnace plant.

One of these connections for use in a central station taking care of such a load as a city load is shown in Fig. 7. The figure is to a certain extent self-explanatory, though the following may be mentioned in connection with the operation of the plant. The stoking of the boiler is carried on at a uniform rate, and but little attention is paid to the manometer on the boilers.

If the boiler pressure exceeds a certain amount, the valve X_2 opens up and the steam flows to the high-pressure turbine, being further divided according to the position of the governor C_2 between the low-pressure turbine and the steam accumulator. If the boiler pressure goes down, the valve X_2 begins to close and less steam goes to the high-pressure turbine. As the speed of rotation of the turbine falls off the governor C_2 opens the main valve and the accumulator begins to give up steam, the low-pressure turbine taking up the load which has been taken off the high-pressure turbine. With such an arrangement, the pressure head on the steam is completely utilized with the exception of the liquid head on the accumulator which amount to about 0.1 atmos. and for practical purposes may be neglected. The bypass with valve X_1 permits the steam to go directly to the accumulator. This valve opens only, however, when X_2 is wide open, i.e., at very low loads, and the purpose of it is to send the steam to the accumulator where it may do some good instead of letting it into the atmosphere through the safety valve.

The only instrument in the boiler house shown on the figure is the accumulator manometer. If the accumulator pressure becomes either too high or too low, the fireman has to manipulate the dampers. With properly dimensioned accumulators, however, this would happen only very seldom under regular conditions of operation. (Paper before the Machinery Board of the Verein deutscher Eisenhuettenleute, abstracted through *Stahl und Eisen*, vol. 42, no. 5, Feb. 2, 1922, pp. 165-171, 9 figs., *dA*)

RAILROAD ENGINEERING (See also Machine Tools)

Hungarian Locomotives and Their Auxiliaries

Locomotives for Hungarian State Railways, Desider Ledacs Kiss. To meet local conditions the Hungarian State Railways adopted for their new locomotives a type with two simple cylinders in place of the four-cylinder compound arrangement, but provided the locomotives with several specialties.

Because of the scarcity of copper, the locomotives constructed soon after the armistice were equipped with boilers of the Brotan type. These boilers are provided with a water-tube firebox, though the boiler shell immediately in advance of the firebox tube plate is cylindrical instead of conical, which is a departure from the standard Brotan type. The firebox is placed above the last coupled wheels and is much wider than the frame. In order to protect the last pair of driving wheels from the radiant heat of the burning coal immediately above the wheels, protector plates were applied. Further, to avoid dead grate surfaces, it was found necessary to have built upon them a sort of multi-stage grate. The forward part of the firebox has a drop grate. There is also in the firebox a semi-automatic smoke consumer, operating on the principle of introducing air through four passages in the brick arch above the grate.

To provide for the circulation of water, the firebox ring of the Brotan-type boiler is connected with the last shell of the boiler barrel. The steam dome containing the balanced slide valve for throttling the steam is located on the first course of the boiler. Over the second course is located a feedwater purifier with eight cells, which has been applied to 3000 locomotives on the Hungarian System.

The locomotive equipment includes also a centrifugal water-intercepting device, or steam desaturator, placed in the dome; also several other specialties, such as a speed recorder, acetylene cab lamps, a feedwater-heating system, etc. The flanges of the forward driving wheels are lubricated by the condensation water from a feedwater pump included in the feedwater-heating system. This system (Knorr) consists of two preheating cylinders, one located on the right-hand side, and the other on the left-hand side of the locomotive. These are connected and serve for preheating the feedwater by the exhaust steam diverted from the exhaust passages of the locomotive. Experience on the Hungarian State Railways has proved that if one-fifth of the exhaust steam from the locomotive cylinders is diverted to the feedwater heater, it will have no appreciable effect on the draft of the locomotive. The exhaust steam is conducted separately into the preheating cylinders located on both sides of the locomotive. In addition to this, the right-hand heater received exhaust steam from the Westinghouse air compressor, and the left-hand heater receives the exhaust steam from the Knorr feedwater pump. The partially-condensed steam from these preheaters is drained underneath the boiler.

The feeding of the boiler is accomplished by the single Knorr feedwater pump and the two Friedman injectors. The left-hand injector and feed pump conveys the feed water through the preheating device, i.e., the water runs through the injector or feed pump first into the left-hand and then into the right-hand preheating cylinder and from there passes through the water purifier into the boiler. This method of operation is used because it has proved the most economical. When the right-hand injector is used, the feedwater runs only through the water purifier and then direct to the boiler.

With the Knorr duplex feed pump, the water cylinder has a steam heating jacket, wherein also the exhaust steam of the pump is conducted. On the up stroke of the piston the water enters through the right-side suction valve and at the same time pushes the water from the upper cylinder chamber through the left-side delivery valve into the delivery pipe. Vice versa, the left-side suction valve and the right-side delivery valve are actuated on the down stroke. The maximum capacity of the pump is 80 gal. per min. The preheating cylinders are filled entirely with straight tubes through which the feedwater makes two passes. The exhaust-steam chamber is also partitioned, so that the steam flows from one end of the heater to the other and back to a point where it is drained, but in an opposite direction to the course of

the feedwater. In order to eliminate the water of condensation, together with the mud which is found to eventually settle in the base of the heater, suitable valves and washout fixtures are provided. (*Railway Review*, vol. 70, no. 9, March 4, 1922, pp. 277–291, 6 figs., *d*)

The Passing of the Cross-Compound Engine. The Canadian Pacific Railway, at its Angus Shops, has converted a number of 10-wheel cross-compound locomotives into simple locomotives of the same type, equipped with superheaters and piston valves. These locomotives will work in sparsely settled sections where the number of passenger and local freight trains must be fairly large but heavy power is not required, and where at the same time severe operating conditions are encountered during the winter months. Under these conditions the modernization of certain classes of old locomotives involves a much lower capital charge than the purchase or construction of new locomotives, and furnishes the railroad with a type of motive power quite as suitable as new locomotives for this service.

Some of the New England railroads have done similar converting, and have even extended it to include small 8-wheel passenger locomotives which have been fitted with new boilers and superheaters for light local passenger service.

The original article gives the details of the alterations carried out in Canada. (*Railway Review*, vol. 70, no. 8, Feb. 25, 1922, p. 265, 2 figs., *d*)

Adhesion and Rack Locomotive for the Dutch State Railways in Sumatra. The adhesion and rack locomotive is designed to operate on very heavy grades on the west coast of Sumatra, a portion of the line being provided with a rackbar of the Riggenbach type. The rack portion has grades of from 5.1 per cent to 6.8 per cent and a total length of 22.5 miles. The radius of the sharpest curves on the rack portion of the line is in the neighborhood of about 500 ft.

Up to the present time, six types of locomotives have been built for service in this portion of the line. The former locomotives were of the 4-wheel coupled type. The design described here is of the 0–10–0 type and was built in Switzerland. The usual system of operation is for a train of, say, 360 tons to be handled by two locomotives, one in the middle of the train and the second at the rear.

The boilers are provided with Schmidt superheaters. The barrel of the boiler consists of two courses, and contains 64 tubes, 12 ft. $9\,^1/_2$ in. long and 18 flues of the same length for the superheater elements. The firebox is of copper. The working pressure is 205 lb. per sq. in.

The driving wheels are $39\,^3/_8$ in. diam., the leading and trailing drivers having a side play of about $^7/_8$ in. The rack wheel is driven from a separate set of cylinders, located above the main cylinders through a jackshaft across the top of the locomotive frame. On this jackshaft is mounted a spur gear which meshes with the gear on the cog-wheel axle. The pitch diameter of the driving rack wheel is $38^3/_8$ in. The gearing between the crank axle and the main cog-wheel axle has a ratio of 1 to 2.033. The gear teeth are of the helical type with the pitch angle of 23 deg.

The locomotive is of the 4-cyl. compound Winterthur type, with all four cylinders outside the frames, two on each side. The lower cylinders are high-pressure and drive the five coupled adhesion axles. The upper or low-pressure cylinders drive the main cogwheel, and are not in operation while the locomotive is running on the adhesion track. While the locomotive is on the adhesion track the exhaust steam from the high-pressure cylinders passes directly to the exhaust pipe. When it is desired to place into operation the low-pressure cylinders which run the rack wheel, the engineer by means of a steam-operated valve, changes the flow of the exhaust steam from the high-pressure cylinders into the steam chest of the rack or low-pressure cylinders. From these cylinders it passes to the exhaust. In this way the locomotive is propelled both by the five-coupled axles and the rack when ascending the rack grades. In order to insure starting with the load on the rack portion of the line, live steam can be admitted directly to the low-pressure or rack cylinders by means of a special valve, so that the locomotive works as a twin engine. The four cylinders are of the same diameter and have the same stroke. They are cast separately in order to facilitate removal and repairs.

Three of the fifteen locomotives are equipped with Caille-Potonie feedwater heaters and double-acting feedwater pump, illustrated in the article. (*Railway Age*, vol. 72, no. 4, Jan. 28, 1922, pp. 263–266, 8 figs., *d*)

SPECIAL PROCESSES (See also Fuels and Firing)

A Simplification in Making Sheet-Metal Pressings. The usual process of manufacturing such sheet-metal parts as automobile fenders involves the use of a male and female die, which means, of course, a considerable expense. A new process of making such articles has been worked out in Australia and is known as the Hydro-Press process.

In this process the female die is of cast iron and requires only to be tooled sufficiently to remove any roughness in the casting so as to give a smooth and even surface. The place of the male die is taken by another cast-iron die containing a "bag cavity." In place of an accurately fitting male die, however, there is placed in the cavity a reinforced rubber bag capable of being expanded by the injection of water under high pressure. The metal sheet to be pressed to shape is laid on the rubber bag. The metal female die which grips the edges of the sheet between itself and the edges of the bag cavity is lowered by the operation of the cams. Water pressure is then turned on by the operator and the resulting expansion of the bag forces the metal to the shape of the female die. The normal working pressures used in Australia vary from 300 to 750 lb. per sq. in. The pressing into shape of the metal sheet is a matter of moments and the release of water and the separation of the dies enables the completed work to be replaced by another sheet of metal. In addition to automobile body panels, aluminum kitchenware has been made by the same process. (*Automotive Industries*, vol. 46, no. 8, Feb. 23, 1922, p. 469, 1 fig., *d*)

STEAM ENGINEERING (See also Thermodynamics, Physics, and Power Plants)

Contribution Toward a Precise Method of Computing Steam-Turbine-Blade Wheels of Variable Thickness, Alex. Fischer. A mathematical article not suitable for abstracting, but the following summary presents the main points. In the first place, the author considers the differential equation given by Stodola for determining the radial displacement of rotating disk wheels. This equation has been hitherto applied only to disks of even thickness and hyperboloidal disks. The equation was only partially solved for the so-called disks of equal strength. The author attempts to give a solution for disks having a section of the form $y = (\pm 1)^n y_0 \left\{ 1 - k \left(\frac{x}{r_0} \right)^m \right\}^n$. Under this classification of disks fall besides disks of even thickness and of hyperboloidal cross-section, also those with trapezoidal and conical section as well as disks of equal strength. For this particular class, the Stodola differential equation may be transformed into the Gauss equation of hypergeometric series. The theory of the Gauss equation is briefly discussed and its application to the present problem shown. The author shows that while in general the solution of the Gauss equation appears in the form of a series, and more particularly hypergeometric series, under certain limited conditions it gives finite expressions for the radial displacements and stresses. The data thus obtained are tested by applying them on disk shapes where the solutions are known and finite. The results are also applied to the complete solution for the case of a disk of equal strength. It is shown in this connection that under the limited conditions prescribed by practical requirements this type of disk fully lives up to its name.

In the second part of the paper is discussed the connection between the differential equation of Stodola for radial displacement, and the differential equation of the stress function proposed by A. Foeppl, and also the differential equation of Stodola for the bending of a horizontal disk of uneven thickness under the influence of its own weight. (*Zeitschrift des Oesterr. Ingenieur- u. Architeken-Vereines*, vol. 74, no. 9–10, March 3, 1922, pp. 46–49, 2 figs., to be continued, *mpA*)

THERMODYNAMICS (See also Heating and Ventilation)

The Specific Heats of Air, Steam and Carbon Dioxide, W. D. Womersley. The author used apparatus of the recording-calorimeter type essentially similar to that designed by the late Prof. Bertram Hopkinson, but improved. Instead of using coal gas he mixed the less complex gases, hydrogen and carbon monoxide, with either air or oxygen. The actual range of the experiments is from 1000 to 2000 deg. cent., the parts in the curves in the original article referring to the lower temperatures being filled from the researches of Swann, and Holborn and Henning. The method of calculations is very completely described.

The results obtained are given in the form of curves. The figures for air and steam are about $7^1/_2$ per cent higher than those of Holborn and Henning at 800 deg. cent., and the author assumes that their values for carbon dioxide are a similar amount too low.

In connection with this investigation the effect of the state of the walls of the containing vessel on the rate of heat flow in a gaseous explosion has also been considered. The author carried out a series of experiments with the Hopkinson calorimeter to find the total heat passed to the walls after an explosion—first, with the walls polished, and then blackened. Coal gas was used in the combustible mixture and five experiments under different conditions were made. The same mixture strength was used throughout, viz., 12.35 per cent of coal gas by volume. The cooling curve and the total heat lost to the walls are shown by a curve in the original article, the maximum temperatures of which are 2123 deg. and 2089 deg. cent. abs., respectively, giving a difference of 34 deg. cent. At the end of one second the gases have cooled to 918 deg. and 859 deg. cent. abs., the difference then being 59 deg. cent. The heat lost to the walls in the two cases when cooling has proceeded to the same temperature is sensibly the same. At one second the heat passed to the walls per square centimeter per gram-molecule is 2.675 and 2.556 calories, respectively.

Another curve in the original article shows the rate of heat flow to the walls at various times during the cooling. From this it is seen that during the first half second the rate of flow is much greater with the walls black than when they are polished. After this time the rates seem to be practically the same in the two cases. The general rate of flow appears to be 16 per cent higher throughout with the blackened walls. From the temperature curves are derived the relations between the rate of heat flow and the difference of mean gas temperature and walls. (*Proceedings of the Royal Society*, Series A, vol. 100, no. A 706, Feb. 1, 1922, pp. 483–498, 10 figs., *et*)

Effect of Variable Specific Heat on Discharge of Gases Through Orifices and Nozzles, Wm. J. Walker. The paper questions the desirability of accounting for abnormal orifice or nozzle discharges by consideration of changes in the value of γ, the index in the equation pv^γ = constant, for adiabatic changes of state. This appears, generally, to have been the custom hitherto, but since the actual adiabatic equation under linear-variable specific-heat conditions is $pv^m e^{\kappa T}$ = constant, the analysis in this paper has been carried out on the latter basis for the purpose of determining, as nearly as possible, what effect such specific-heat variation has on discharges. An exact solution does not appear to be derivable, but the method of analysis adopted here may be carried to any degree of accuracy required. The method of analysis is somewhat similar to that adopted in a previous paper (The Effect of Variable Specific Heat on Thermodynamic Cycle Efficiencies, *Philosophical Magazine*, September, 1917), dealing with another effect of variable specific heat. The result obtained in the present paper brings out prominently the fact that the error in computing discharges (by the usual constant-specific-heat theory) increases as the density of the medium in the reservoir is diminished. This fact appears to have been neglected in previous considerations of the subject. It is pointed out, also, that by means of the discharge formulas obtained the method of orifice discharge may be used as a reliable and convenient one for the determination of specific-heat variations with temperature. (*The London, Edinburgh, and Dublin Philosophical Magazine and Journal of Science*, vol. 43, no. 255, March, 1922, pp. 589–593, *tm*)

Influence of Colors on Heat Absorption of Paints and Bricks, Maj. C. R. Satterthwaite. Data of experiments on influence of color and heat absorption of various materials in hot sunlight were carried out in the Soudan during the period of 1915–18 by G. W. Grabham. The experiments were on the properties of various materials and fabrics used for clothing, but tests were also carried out on painted surfaces and bricks.

For the purpose of the experiments, cylindrical tin flasks $12^1/_2$ cm. and $7^1/_2$ cm. in diameter were adopted. They were provided with necks and corks through which thermometers were inserted so that the bulbs were placed freely at about the center of the flasks.

In the principal experiments the flasks were laid out on a white sheet resting on a doubled woolen blanket, to eliminate as far as possible disturbing factors due to heat absorption by their surroundings. They were set at intervals of about 30 cm., and arranged in order of their apparent tints so that the lighter-colored flasks were next each other and distant from the darker ones. These precautions were taken to reduce effects due to radiation from one flask to another, such as might have interfered had a black flask been near a light-colored one. Standards of reference were provided by other flasks, the white being coated with a lime wash which gave a dead-white surface, while the other was coated with a mixture of lampblack and varnish which dried with a dull-black surface.

From the mean of several observations it was found that, with the "White Standard" (lime wash) at 115.9 deg. fahr., the following colors showed the excess temperatures given below.

	Deg. Fahr.
Cream paint	11.5
Khaki paint	22.5
Cement wash	26.8
Black paint	35.2

In experiments on bricks, a detailed procedure of which is given in the original article, it was found that burnt brick was much hotter than sun-dried brick, which may have been due both to direct heat absorption and also to texture. (*Journal of Hygiene*, vol. 19, no. 3, Jan., 1921, abstracted through *The Royal Engineers' Journal*, vol. 35, no. 3, March, 1922, pp. 129–132, *e*)

VARIA

Weighing by Substitution. Substitution weighing is of importance when it is desired to obtain very accurately the weight of some particular object and when calibrating or adjusting weights in the process of standardizing them.

The scheme of weighing by substitution is as follows: For standardizing weights the standard is first placed on the scale pan or platform designed to receive it and counterpoised by any convenient material. When the balance of the beam is obtained the standard is removed, the weight to be compared is substituted and the correction is determined from the small weights that have to be added or subtracted to establish the same balance as before.

Where the weight of an object is desired and its weight is not already known approximately, it is first placed upon the platform and balanced by a suitable counterpoise. It is then removed and standard weights substituted until the same balance is established as before. The weight of the object is then equal to the weights substituted for it. The method of substitution weighing is rendered precise by observing certain details explained in the original paper.

As explained by the Bureau of Standards, the process may be used for obtaining weighings of considerable refinement with ordinary forms of compound lever scales. (*Technologic Paper of the Bureau of Standards*, no. 208, Feb. 21, 1922, pp. 177–192.)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society.

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A.S.M.E.

Metallic Corrosion Under Investigation

THROUGHOUT the country during the past year a considerable amount of research on the general subject of corrosion has been carried on. This activity, in spite of the general relaxation in chemical and metallurgical research, is due probably to the extreme importance of many of the problems and to the large savings in capital and labor that would result in their solution. The laboratories of the Government, private concerns and the colleges are participating in this work.

It was for the purpose of coördinating this research activity that The National Research Council recently appointed a committee on this subject to function under its Division of Research Extension. Mr. W. M. Corse, Gen. Mgr., Monel Metals Products Corporation, Bayonne, N. J., is Chairman and Dr. Colin G. Fink of 101 Park Avenue, New York, is Secretary of the Committee.

This Committee is, first, to serve as a general clearing house for information on the subject and, second, to devote its attention essentially to a fundamental scientific study of corrosion in all its aspects. It desires to get quickly in touch with the work which is being done on corrosion whether through societies, associations, institutes, universities, private laboratories, or industrial laboratories. It is known that the following thirteen organizations are at present interested in the general problem through committee activity.

American Society for Testing Materials
Bureau of Standards
American Institute of Electrical Engineers
American Gas Association
American Electric Railway Association
American Railway Engineering Association
American Water Works Association
National Electric Light Association
National Gas Association of America
Engineering Foundation
The American Electrochemical Society
Bureau of Mines
National Canners' Association

The corrosion problem is being attacked from two more or less different angles. In the one case every effort is being made to arrest the corrosion of the materials now in use, in the other new materials are substituted and tried out. A partial list of distinct problems of corrosion which demand investigation are listed below, each being centered around some specific material or article of manufacture.

Condenser Tubes
Automobile Radiators
Underground Cables
Buried Iron Pipes, Posts, etc.
Fence Wire
Flues, Stacks, Stove Pipes
Steel Ships and Ship Fittings
Roofing Materials
Mine Pumps and other Mine Equipment
Atmospheric Corrosion of Brass
Atmospheric Corrosion of Bronzes
Alloys Resistant to High Temperature
Corrosion of Zinc Cathodes
Contact Metals or Alloys
Catalyzer Metals or Alloys
Cutlery Steels
Acid Tank Linings
Corrosion of Nickel-Plated Ware
Boiler Tubes
Fire Boxes
Insoluble Anodes

Cast Iron when Affected by the Presence of Small Amounts of Other Elements. Three general problems involved in this research are (1) Velocity of corrosion as affected by (*a*) temperature fluctuations, (*b*) alternate dry and moist surface, (*c*) presence of foreign materials, (*d*) presence of oxide or carbonate of one or the other constituent of the alloy, (*e*) crystal structure and intercrystalline cement; (2) properties of the surface film: (*a*) coefficient of expansion as compared with that of the underlying metal; (*b*) its chemical composition; (*c*) porosity; (*d*) flexibility or ductility; (*e*) coefficient of adhesion; (*f*) speed of renewal of "healing;" (*g*) relative hardness; (*h*) how effected during mechanical working; and (3) corrosion and bacteria.

A more complete micrographic investigation of the changes taking place in the film and the metal underneath, during the process of corrosion, is very desirable. Furthermore, progress will come more rapidly as soon as it is agreed what shall constitute a standard test when used to determine the relative corrodibility of two samples. At present it is almost impossible to compare the results of one observer with those of another, even when both of them have work on the same materials in their tests.

Within the last year, however, decided progress has been made in the study of cutlery steels, metals and alloys for mine equipment, cable sheath, insoluble anodes, alloys resistant to high temperatures, and the corrosive action of molten metals such as zinc, tin, etc. But the solution of the corrosion problem, as a whole, in spite of its long past history, is still in its "infancy" and it is only through coöperative effort and a free discussion of results (those usually suppressed as well as those suitable for advertising purposes) that consistent forward strides are possible.

Research Résumé of the Month

A—Research Results

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a resume of research results with formulas or curves where such may be readily given, and to report results of non-extensive researches which in the opinion of the investigators do not warrant a paper.

Apparatus and Instruments A2-22. WEIGHING BY SUBSTITUTION. This paper describes a plan for making substitution weighings which can be applied in using either equal-arm balances or compound lever scales. It is based upon the method developed by the Bureau of Standards in the test and standardization of the 10,000-lb. weights which form a part of its railroad track-scale testing equipments and in which a maximum accuracy is desired. The interest of the practical scale man coming in contact with the work of the Bureau has been aroused in its methods, and the present publication is prepared mainly in response to a general demand for an outline of a systematic method for carrying out substitution weighing. As the result of suggestions of these men engaged in the actual maintenance and testing scales, the procedure for taking data and conducting the routine of the test has been made to conform closely with that used by the Bureau of Standards in the precision test of railroad-track and grain-hopper scales; and the form for recording the data and making computations which is presented has been arranged to be as near to that used in the scale-testing work as is practical.

The general matters covered by the paper comprise, first, a general description of the theory of weighing by substitution; the preparation of the scale for weighing so that the swings of the beam can be read on the graduated scale; the method for obtaining the positions of the equilibrium of the beam from the readings taken on it while moving; the method of removing and substituting weights; and a description of the details to be observed in preparing the scale and making observations, and the practice to be followed in making the computations.

The method is of especial value in the calibration of a large number of weights of the same denomination. The method is equally applicable, however, for determining accurately the unknown weight of any object. Technologic Paper of the Bureau of Standards, No. 208, by C. A. Briggs and E. D. Gordon. The complete paper may be purchased from the Superintendent of Documents, Government Printing Office, Washington, D. C. Price, 5 cents.

Instruments and Apparatus A2-22. WEIGHING BY SUBSTITUTION. See *Apparatus and Instruments A2-22.*

Thermal Conductivity A1-22. THERMAL CONDUCTIVITY OF SOME WEARING MATERIALS. Thermal Conductivity of Woolen, Cotton, Linen and Silk Materials.—Measurements of the conductivity of samples of knitted and woven materials have been made by the disk method of Lees, corrected for variation of emissivity with temperature. From one to eight or more layers of one of the materials were held between two copper disks with a pressure of 6 gm./cm²., one disk being heated electrically by a coil between it and a third disk, and all three radiating to a constant-temperature enclosure. The temperature of the samples was 30 to 40 deg. The values obtained are greater for dense than for loosely woven or knitted samples, ranging from 76 for unspun silk,

94 to 120 for wool, 101 to 122 for silk, 131 for flannelette, 158 to 167 for linen, and 168 to 184 for cotton, all times 10^{-6}. The results come out greater for several layers than for a few, and greater for moist than for dry samples. When the materials are arranged according to conductivity for equal weight instead of equal thickness, the order depends largely on the looseness of texture, beginning with unspun silk, loosely woven wool and knitted artificial silk, and ending with closely woven silk cotton and linen.

The above is a synopsis of a paper which appeared in the November, 1921, issue of *The Physical Review*. Address E. S. Rood, Mount Holyoke College, Mass.

Thermal Conductivity A2-22. Variation with the Temperature of the Thermal Conductivity of Cast Iron. Variation with Temperature of the Thermal Conductivity of Soft Gray Cast Iron, 195 to 542 deg. cent.—The sample used contained 3.5, 2.2 and 0.64 per cent, of C, Si and Mn, respectively, and was cast into the form of a cylindrical shell 3 cm. thick, joined with a hemispherical bottom. The temperature differences between the liquids inside and outside the shell, which amounted to from 3 to 6 deg. with an input of from 0.24 to 1.6 kw., were measured with thermocouples silver-soldered in the ends of brass tubes. Since even though these tubes were pressed against the iron surfaces, the temperatures thus measured differed more or less from the actual temperatures of the surfaces, the absolute values found for the conductivity are too low; but the results indicate that the conductivity at 542 deg. is between 2 and 3 times its value at 195 deg. cent.

A brief but interesting report on this subject is printed in the March, 1922 issue of *The Physical Review*. It records the progress made thus far by Elmer E. Hall of the Department of Physics, University of California, Berkeley, California.

Cement and Other Building Materials A2-22. Method of Proportioning Concrete Materials—Screened and Unscreened Gravel. Bulletin No. 60 just received from the Engineering Experiment Station of Iowa State College. See Synopsis of the Process of Making Concrete.

The conclusions with respect to the theory of proportioning which may be drawn from the numerous strength tests reported in this Bulletin, are: (1) If the consistency remains the same the strength varies with the coarseness of the aggregate, or, for the same consistency, the finer the aggregate the more cement (to maintain the strength), is required: (2) The finer the aggregate the more water is required to produce the required consistency; (3) And, therefore, combining 1 and 2, the more water used in mixing, the more cement is required to maintain the strength. Address R. W. Crum, Iowa State College, Ames, Iowa.

Steel, Its Treatment and Products A2-22. Corrosion of Steels. Laboratory work relating to the determination of the relative resistance of certain alloy steels to corrosion when submitted to combined weathering and immersion in distilled water was completed during the month. Based on exposure of 19 days, the polished samples of steel showed the best resistance to corrosion in the order given below:

1 Annealed stainless steel (C–0.15%, Cr–13%)
2 Annealed high-chromium and high-nickel steels
3 Forged stainless steel
4 Cast-iron-chromium alloy (C–0.04%, Cr–6.5%)
5 Annealed chromium steel (C–0.20%, Cr–8.6%)
6 Annealed chromium steel (C–0.30%, Cr–5.72%)
7 Annealed chromium steel (C–0.28%, Cr–3.90%)
8 Pure iron
9 Iron-carbon alloy (C–0.45%).

These tests have been conducted in the laboratories of the Bureau of Standards, Washington, D. C. Address Dr. S. W. Stratton, Director.

Steel, Its Treatment and Products A3-22. Effect of Heat Treatment on the Mechanical Properties of 1 Per cent Carbon Steel. Technologic Paper No. 206 of the Bureau of Standards on this subject will be ready for distribution by the Superintendent of Documents, Government Printing Office, this city, during the month of March. The price is 15 cents per copy.

This gives the effects of varying time-temperature relations in heat treatment on tensile and impact properties, hardness, and structure of 1 per cent carbon steel, as follows: *(a)* Effect of temperature variations in hardening; *(b)* time of hardening temperatures above Acm between the Ac_1 and Acm transformation; *(c)* effects of tempering steels hardened in different ways and effects of "soaking" just under the lower critical range, and *(d)* comparison of oil and water hardening for production of definite strengths. Under the described conditions of treatment and test, the features observed are described in detail under eight headings.

B Research in Progress

The purpose of this section of Engineering Research is to bring together those who are working on the same problem for cooperation or conference, to prevent unnecessary duplication of work and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

Paints, Varnishes and Resins B1-22. Paint on Wood. The National Research Council and the Engineering Foundation are completing arrangements for a thorough research into the protective covering of wood of all kinds. Owing to the nature of some of the tests involved this research will extend over a period of eight to ten years. The plans call for a study in laboratory and field by methods to be devised and improved from time to time, of paints, varnishes and other protectives now commonly used and others which may be suggested, to determine best materials for various purposes, conditions and woods and the most effective methods of application, durability and appearance.

Among objects sought are: *(a)* control of dimensional changes of wood due to absorption and loss of moisture; *(b)* preservation of wood for economic reasons, including conservation of forests; *(c)* economies in use of protective and finish coatings for wood and of the labor required for their application. It is proposed to carry this work forward with the full coöperation of the Forest Products Laboratory of the Department of Agriculture at Madison, Wis., the Bureau of Standards and the American Society for Testing Materials in addition to the lumber, woodworking and paint industries of the country. Address Alfred D. Flinn, Secretary, Engineering Foundation 29, West 39th Street, New York City.

Heat B1-22. Heat of Fusion and Specific Heat of Metals. The Committee on Grants of the American Association for the Advancement of Science has recently assigned one hundred and fifty dollars to Professor A. W. Smith, Ohio State University, Columbus, Ohio, in support of this work on the latent heat of fusion and the specific heat of metals.

Steel, Its Treatment and Products B2-22. Electric Furnace vs. Open-Hearth Silico-Manganese Spring Steels. It is more or less generally recognized that steels of the same composition in so far as the elements used are concerned require variations in heat treatment to produce similar properties. This applies to comparisons between heats made by the same type of process and steels produced by different processes. A series of tests was completed during the past month at the Bureau of Standards on samples of electric and open-hearth heats of silico-manganese spring steels carrying equal proportions of C, Mn, P, S, and Si. The tests included microscopic examination, tensile test, and determination of proportions of certain gases present, particularly nitrogen and hydrogen. In general, the microstructure of the electric steel was somewhat different from that observed in the open-hearth when both steels were subjected to the same heat treatment.

Under certain thermal treatments, distinct differences in tensile properties were observed, but these were largely obliterated by a preliminary normalizing quench from a high temperature. It was found that the proportion of oxygen present in these steels was practically the same, about 0.028 per cent, and independent of the heat treatment applied. The nitrogen in the original rolled samples of electric steel was approximately twice that of the open-hearth and independent of the heat treatment. However, in the case of the electric steel, the proportions of nitrogen were dependent upon the heat treatment.

Iron and Steel B1-22. Iron for Use in Manufacture of Car Wheels. A new investigation has been inaugurated to study the relation between the mechanical composition and physical properties of cast iron of the car-wheel type. In the preliminary work particular attention is to be paid to the question of sulphur and phosphorus content of the iron. The irons will be made in the Ajax-Northrup high-frequency furnace which permits a very close regulation to any desired composition. The following tests will be made on the cast material: Transverse, tensile, impact, hardness, and wear. The depth of the chill of the chilled specimens will also be noted.

This work should prove of great value in the drawing up of specifications for chilled iron car wheels. Address Dr. S. W. Stratton, Director, Bureau of Standards, Washington, D. C.

Welding B1-22. Welding of Street-Railway Joints. The American Electric Railway Association through its Committees on Way Matters initiated the formation of the Committee on Welded Rail Joints for the purpose of having an authoritative investigation made of the various types of welded rail joints now in commercial use. The American Bureau of Welding as the coördinating agency in the general field of welding research and standardization has organized a large Committee comprising over thirty experts on welded rail joints.

Welding is being very widely used in making street-railway joints and more or less trouble has been experienced in all types of welded joints from breakage. Little or no scientific data exists as to correct procedure to be followed in making welds by the various processes. Several of the larger companies are spending many thousands of dollars per year on such joints.

A small Executive Committee has prepared a thorough questionnaire on the four types of welded joints now in use, namely, cast iron, electric seam, resistance and thermit. These were sent out to the members of the Committee and replies are being forwarded to the Society. From the answers to this questionnaire it is expected that a critical summary will be prepared of our present knowledge based upon all the available experience in this field. A program of research will then be outlined and different parts of the program assigned to an appropriate laboratory or in the case of field experiments to one or more appropriate operating companies. These assignments would, of course, cover the men under whom the specific experiments will be conducted. Address Wm. Spraragen, Secretary, American Bureau of Welding, 29 West 39th Street, New York.

Corrosion B1-22. Metallic Corrosion. Realizing the great loss which industry experiences each year as a result of corrosion in its various forms, The National Research Council recently appointed a committee to correlate the activity already under way. It recognizes the start that has been made by committees which are composed of representatives of thirteen organizations associated with a number of large firms and it desires first, to be a clearing-house for research information, and second, to devote its attention to a fundamental scientific study of the subject. Address Dr. Colin G. Fink, Secretary of the Committee, 101 Park Avenue, New York.

Electrolysis B1-22. Metallic Corrosion. See *Corrosion B1-22.*

D—Research Equipment

The purpose of this section of Engineering Research is to give in concise form notes regarding the equipment of laboratories for mutual information and for the purpose of informing the profession of the equipment in various laboratories.

Iron and Steel D1-22. Titanium in Steel and Bronze. The facilities of the Physical Laboratories of the Titanium Alloy Manufacturing Company are now offered to manufacturers and others interested in metallurgical and mechanical lines.

Equipped primarily for research and experimental work of an exacting nature, the apparatus is such as to insure accurate results. The Physical Laboratories are comprised of four units: testing laboratory, metallographic laboratory, room for experimental heat-treating and small experimental foundry.

They are equipped for most of the usual physical tests, such as hardness, tensile, impact, alternating stress, electrical conductivity, etc., etc. In the heat-treating department they are able to do heat-treating of any character, but only on an experimental scale. The experimental foundry is equipped only for work on metals which can be satisfactorily melted in crucibles. The work of these laboratories was one of the prime factors in the development of Aluminum Bronze in this country. Address George F. Comstock, Physical Testing Laboratories, Titanium Alloy Manufacturing Company, Niagara Falls, New York.

E—Research Personnel

The purpose of this section of Engineering Research is to give notes of a personal nature regarding the personnel of various laboratories, methods of procedure for commercial work or notes regarding the conduct of various laboratories.

Research Agencies E3-22. Research Laboratories in Industrial Establishments of the United States. This is the tile of a Bulletin of the National Research Council recently issued by the National Research Council. This publication is a revised and enlarged edition prepared by Ruth Cobb of the Bulletin originally compiled by Alfred D. Flinn, Secretary Engineering Foundation. Following a brief introduction the information is classified in four ways: (*a*) Alphabetical list of laboratories, (*b*) Index to subject classification of laboratories, (*c*) Subject classification of laboratories, (*d*) Address list of directors of research. Address The National Research Council, Washington, D. C.

F—Bibliographies

The purpose of this section of Engineering Research is to inform the profession of bibliographies which have been prepared. In general this work is done at the expense of the Society. Extensive bibliographies require the approval of the Research Committee. All bibliographies are loaned for a period of one month only. Additional copies are available, however, for periods of two weeks to members of the A.S.M.E. These bibliographies are on file at the office of the Society.

Electrochemistry F1-22. Electrolytic Corrosion of Pipe Lines and Structural Materials. A bibliography of $8^1/_2$ pages. Search 3474.

Fuel Utilization F1-22. The Smoke Problem. An interesting review of the history and technical information relating to smoke abatement is contained in a brief report prepared by O. P. Hood, Chief Mechanical Engineer, U. S. Bureau of Mines. A bibliography on this subject forms part of this Report, No. 2323.

Properties of Engineering Materials F1-22. Platinum. In response to numerous inquiries the Bureau of Mines has prepared a report (No. 2326) on platinum, its properties, uses, occurrence, metallurgy, refining and its substitutes. This report also contains a short bibliography.

WORK OF THE A.S.M.E. BOILER CODE COMMITTEE

The Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York, N. Y.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in Mechanical Engineering.

Below are given the interpretations of the Committee in Cases Nos. 384 to 390 inclusive, as formulated at the meeting of March 2, 1922, and approved by the Council. In accordance with the Committee's practice, the names of inquirers have been omitted.

Case No. 384

Inquiry: Is it permissible, under Par. 191, to straighten the edges of bottom plates of fired pressure vessels by hand hammering on an anvil which is bolted to the edges of the sheet where the bottom plate has been cold pressed with sectional dies to the correct radius?

Reply: It is the opinion of the Committee that the straightening of edges of bottom plates of fired pressure vessels by hand hammering is prohibited by Par. 191 of the Code. Attention is called to the fact that with proper dies and manipulation, it is possible to properly form the plate.

Case No. 385

Inquiry: Does the requirement in Par. 6 for the material to be used in braces apply to the structural members referred to in Pars. 201 and 225?

Reply: It is the opinion of the Committee that the structural members referred to in Pars. 201 and 225 come under the classification of braces in Par. 6 and should be of material that conforms to the specification for steel bars.

Case No. 386

Inquiry: Is it the intent of Par. 250 and 251 that expanders of the Prosser type may not be used for attaching tubes and nipples in fire-tube and water-tube boilers, and that expanders of the roller type are compulsory?

Reply: It was the intent of Pars. 250 and 251 to specify that the tubes be suitably expanded by other than a peening process and the exclusion of the use of a Prosser-type expander was not contemplated by the Committee.

Case No. 387

Inquiry: Does the tolerance of 20 per cent in the phosphorus and sulphur limits as given in Par. 84*b* of the Boiler Code permit the acceptance of steel castings with 0.06 per cent of phosphorus and sulphur?

Reply: The tolerance of the phosphorus and sulphur limits as given in Par. 84*b* of the Boiler Code, applies only to the check analysis from the casting, which check analysis is not compulsory, and which is not subject to the tolerance. The reason is that the ladle analysis gives a fair average of the constituents of the steel, whereas locally in the casting, the chemical constituents may vary slightly from the average; hence the tolerance permitted.

Case No. 388

Inquiry: Would a continuous feed pipe, which is connected so as to pass lengthwise through a boiler drum with feed valves at each end of the pipe, the pipe being drilled with a number of holes $^1/_2$ in. in diameter or over, spaced along its length for discharging the water into the drum, the combined area of the holes being at least equal to that of the cross-section of the pipe, be acceptable under the requirements of Par. 314 of the Code?

Reply: It is the intent of Par. 314 of the Code, that the feed pipe

of the boiler shall have an open end or ends inside the boiler, and it is the opinion of the Committee that the arrangement submitted is the equivalent of an open-ended pipe and should be allowed. (See Case No. 358.)

Case No. 389

Inquiry: Is it the intent of the last sentence of Par. 308 of the Code to restrict the use of globe valves of the angle type for blow-off connections? It was pointed out that angle globe valves have a practically straightway passage through them and offer no dam or obstruction to cause accumulation of sediment.

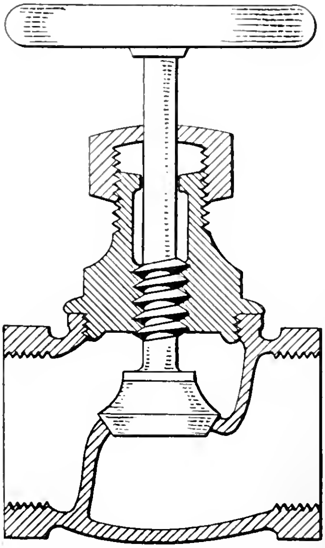
Reply: It was the intent of Par. 308 that straightway globe valves of the ordinary type or valves of such type that dams or pockets can exist for the collection of sediment, shall not be used on such connections. Accordingly, a revision of the last sentence of Par. 308 has been suggested to read as follows:

> Straightway globe valves of the ordinary type as shown in the accompanying illustration, or valves of such type that dams or pockets can exist for the collection of sediment, shall not be used on such connections.

Case No. 390

Inquiry: Would it be permissible, under the rules in the Code to construct an electrical steam generator formed of large electrodes immersed in water within an enclosed vessel, for producing steam at 100 lb. gage pressure from electrical energy? The generator is to have a circular shell of a size in excess of the miniature boiler limit in outside diameter, with flat cast-steel head having the necessary openings for access, bolted to cast-steel flanges riveted to the circular shell.

Reply: Such a construction is not fully covered by the Code. In view of the impossibility of computing these strains in the flat circular heads with exactness when it is desired to build boilers of this type, the Committee would recommend that a test to destruction be made on a full-sized generator as provided for in Par. 247 of the Code.



Type of Globe Valve Referred to in Par. 308 of Boiler Code

RULES FOR THE CONSTRUCTION OF MINIATURE BOILERS

FOR over two years a Sub-Committee of the Boiler Code Committee has been engaged in formulating Rules for the Construction of the so-called Miniature Boilers, which is to form Section 5, Part 1 of the A.S.M.E. Boiler Code. There has been considerable demand for such a Code embodying special rules for boilers of small size that come within this classification in which the requirements for power boilers of average size are scarcely necessary or justified. Several preliminary reports upon this Code have been considered by the Boiler Code Committee and two revisions thereof have been submitted to the steam boiler industry for purposes of discussion. In connection with the 1921 Annual Meeting of the Society, a public hearing on the proposed rules was held and the manufacturers were there invited to discuss the proposed regulations. The report is here published for the information of the membership. Anyone desiring to discuss the report is requested to address the Secretary of the Boiler Code Committee, 29 West 39th St., New York, N. Y.

A.S.M.E. Boiler Code

PART I SECTION 5

Rules for the Construction of Miniature Boilers

M-1 *Definition.* Boilers to which the classification "Miniature" applies, embrace fired pressure vessels which do not exceed the following limits:

16 in. inside diameter of shell
42 in. length of shell
20 sq. ft. total heating surface
100 lb. per sq. in. maximum allowable working pressure.

Where any one of the above limits is exceeded, the rules for Power Boilers shall apply.

M-2 Specifications are given in these Rules, Pars. 23–178 of Part I, Section 1 of the Code, for the important materials used in the construction of boilers, and the materials for miniature boilers, for which specifications exist, shall conform thereto, except that in lieu of definite specifications for boiler-plate material, there may be used for the shells or drums of miniature boilers, seamless drawn shells with integral heads, or seamless or extra heavy lap-welded steel or iron pipe or tubing, provided it is of open-hearth material and the weld is formed by the forging process. Owing to the small size of the parts of miniature boilers, stamping as required by Par. 36 of the Rules for Power Boilers need not be visible after completing the boiler, provided the manufacturer certifies on the data slip accompanying the boiler that the material is in accordance with the requirements of the A.S.M.E. Code for Miniature Boilers. Provisions shall be made by the manufacturer whereby he shall be able to supply complete information regarding the material and details of construction of any boiler built under the Miniature Boiler Code.

M-3 Steel plate when used for any part of a miniature boiler where under pressure, shall be of the firebox or flange grades, but in no case shall steel of less than $^{1}/_{4}$ in. thickness be used for riveted shells or less than $^{3}/_{16}$ in. thickness for seamless shells. The heads, if used as tube sheets with tubes rolled in, shall be at least $^{5}/_{16}$ in. thick.

M-4 The construction of miniature boilers, except where otherwise specified, shall conform to that required for power boilers. The factor of safety and method of computing the maximum allowable working pressure shall be the same as for power boilers.

M-5 Heads or parts of miniature boilers when not exposed to the direct action of the fire may be made of cast iron or malleable iron provided it complies with the requirements in Part I, Section 1 of the Boiler Code for the headers of water-tube boilers.

M-6 Steam-generator elements of not over 600 cu. in. in volume may be made of cast copper or bronze having a copper content of not less than 90 per cent and wall thickness of not less than $^{1}/_{4}$ in. Such generators shall be equipped with at least two brass washout plugs of not less than 1-in. iron-pipe size, and shall be tested to a hydrostatic pressure of 600 lb. per sq. in.

M-7 Circumferential riveted joints, where used, shall conform to the requirements in Par. 184 of Part I, Section 1 of the Code. Autogenous welding may be used for joints in miniature boilers where the strain is carried by other construction which conforms to

the requirements of the Code and where the safety of the structure is not dependent upon the strength of the weld.

M-8 Tubes may be made of wrought iron, steel, drawn copper or drawn brass. Fire tubes $1^1/_2$ in. and over shall have both ends substantially expanded into the tube sheet by rolling and beading. Fire tubes less than $1^1/_2$ in. shall be expanded and beaded, or expanded and welded. The gage of the tubes shall not be less than that specified for water-tube boilers and fire-tube boilers as specified in Pars. 21 and 22 of Part I, Section 1 of the Code.

M-9 All rivet holes shall be drilled full size, or they may be punched not to exceed $^1/_8$ in. less than full diameter and then drilled or reamed to full diameter.

M-10 The calking edges of plates, buttstraps and heads shall be beveled to an angle not sharper than 70 deg. to the plane of the plate, and as near thereto as practicable. Every portion of the sheared surfaces of the calking edges shall be planed, milled or chipped to a depth of not less than $^1/_8$ in. Calking shall be so done that there is no danger of scoring or damaging the plate underneath the calking edge, or splitting the edge of the sheet.

M-11 Every miniature boiler shall be fitted with not less than three brass washout plugs of 1-in. iron-pipe size, which shall be screwed into openings in the shell near the bottom, reinforced to give four full threads. All threaded openings in the boiler shell shall be provided with a riveted or welded reinforcement if necessary, to give four full threads therein.

M-12 Every miniature boiler shall be provided with at least one feed pump or other feeding device, except where it is connected to a water main carrying sufficient pressure to feed the boiler.

M-13 Each miniature boiler shall be fitted with feedwater and blow-off connections, which shall not be less than $^1/_2$-in. iron-pipe size. The feed pipe shall be provided wth a check valve and a stop valve. The feedwater may be delivered to the boiler through the blow-off connection, if desired. The blow-off shall be fitted with a valve or cock in direct connection with the lowest water space practicable.

M-14 Each miniature boiler for operation with a definite water level shall be equipped with a glass water gage for determining the water level. The lowest, permissible water level shall be at a point one-third of the height of the shell, except where boiler is equipped with internal furnace, when it shall be not less than one-third of the length of the tubes above the top of the furnace.

M-15 Each miniature boiler shall be equipped with a steam gage, having dial graduated to not less than one and one-half times the maximum allowable working pressure. The gage shall be connected to the steam space or to the steam connection to the water column, by a siphon tube or equivalent device that will keep the gage tube filled with water.

M-16 Each miniature boiler shall be equipped with a sealed spring-loaded pop safety valve, not less than $^1/_2$ in. diameter, connected direct to the boiler, independent of any other connection. The safety valve shall be plainly marked by the manufacturer with a name or an identifying trademark, the nominal diameter, the steam pressure at which it is set to blow, and A.S.M.E. Std. The minimum relieving capacity shall be determined on the basis of 3 lb. of steam per hour per square foot of boiler heating surface.

M-17 Each steam line from a miniature boiler shall be provided with a stop valve located as close to the boiler shell or drum as is practical.

M-18 Where miniature boilers are gas-fired, the burners used shall conform to the requirements of the American Gas Association, as given in the Appendix. The burners shall in such cases be equipped with a fuel-regulating governor, which shall be automatic and regulated by the steam pressure. This governor shall be so constructed that in the event of its failure, there can be no possibility of steam from the boiler entering the gas chamber or supply pipe.

M-19 All boilers referred to in this section shall be plainly marked with the manufacturer's name, the maximum allowable working pressure which shall be indicated in arabic numerals, followed by the letters "lb.," and the serial number. All boilers built according to these rules shall be marked A.S.M.E. Min. Std. Individual shop inspection is not required for miniature boilers.

A data sheet shall be filled out for each boiler and signed by the manufacturer, this data sheet to include the most important items and to be numbered. In addition to this, the complete data sheet required for power boilers shall be filled out and preserved by the manufacturer for each lot of steel and each lot of boilers manufactured therefrom. The complete data sheet shall be marked to indicate to which boilers it applies and the manufacturer shall furnish copies of this complete data sheet when requested to do so by the owner of any one of the boilers. In requesting the complete data sheet the owner should forward the number of the boiler which would be stamped thereon in order that the manufacturer may readily identify the complete data sheet applying to the boiler.

APPENDIX

Gas Burner Specifications—American Gas Association

Each burner shall be equipped as follows:

1 With a separate one-quarter-turn gas cock
2 With either an adjustable gas orifice or a removable brass orifice of a fixed drilling to meet the local condition
3 With an adjustable air shutter capable of giving complete shut off; a lock washer or screw should hold the shutter so securely that accidental shifting of the shutter is impossible
4 The mixing tube, should be at least six times as long as its minimum diameter
5 When the air mixer, mixing tube and burner are made in separate parts, they shall assemble so that there is no reduction in internal area at the point of their connection in the direction of the gas flow.

The burner proper shall preferably be of a one-piece cored casting.

The port openings shall be drilled, or if assembled, shall be of uniform size.

The burner shall be capable of operating satisfactorily without a wire gauze.

For satisfactory operation a burner should have sufficient flexibility to burn with a blue flame at full load and not flash back when shut down to the gas flow required to just maintain radiation losses.

A positive pilot-lighting burner shall be provided.

Sectional Committee on Standardization of Gears Proposes Five Standards

THE decision to organize this Sectional Committee under the Rules of the American Engineering Standards Committee was announced in the September, 1920 issue of MECHANICAL ENGINEERING. It was there stated that the American Gear Manufacturers Association and The American Society of Mechanical Engineers had been designated Sponsors for this Committee by the A.E.S.C.

At the first meeting held on June 23, 1921 Mr. Benjamin F. Waterman was elected chairman, Mr. Earle Buckingham, vice chairman, and Mr. John P. Kotteamp, secretary. The field in which this Committee is to work was looked over in a general way and Mr. Buckingham was asked to prepare for the use of the members of the Committee a review of the Present Status of Gear Standardization in the United States and Europe. A copy of this statement with reprints of all known gear standards was then placed in the hands of each member of the Committee before the next meeting which was called for October 27, 1921. A third meeting was held on January 19, 1922.

Owing very largely to the excellent preliminary work in this field which the American Gear Manufacturers Association has carried on for a number of years the Sectional Committee is now able to submit a Preliminary Report covering five sub-divisions of its work, namely, (a) Gears and Pinions for Electric Railway Service, (b) Gray-Iron Industrial Spur Gears, (c) Specifications for Forged and Rolled Gear Steels, (d) Specifications for Steel Castings for Gears and (e) Standard Specifications for Brass and Bronzes for gears.

Two reasons prompt the Sectional Committee to publish these proposed standards at this time: *First*, it desires at all times to keep the public fully informed concerning the progress of its work and *second*, it needs the constructive criticism and suggestions of those most interested in the subject. Kindly address the Secretary of the Committee Mr. John P. Kotteamp, care of Pratt Institute, Brooklyn, N. Y. After a reasonable time has elapsed the Sectional Committee will formally present these standards to the two sponsor bodies, who will, on approval, place them before the American Engineering Standards Committee.

Gears and Pinions for Electric Railway Service

CASE-HARDENED FORGED-STEEL GEARS

MANUFACTURE

1 *Material.* All blanks for gears shall be made from open-hearth steel which has been thoroughly worked to secure a homogeneous dense material, free from all injurious defects.

CHEMICAL PROPERTIES AND TESTS

2 *Chemical Properties.* The steel shall conform to the following requirements as to chemical composition.

Carbon.....0.20 per cent, not less than 0.12 per cent nor more than 0.28 per cent.
Manganese..0.50 per cent, not less than 0.40 per cent nor more than 0.60 per cent.
Phosphorus.....not over 0.05 per cent.
Sulphur........not over 0.05 per cent.

3 *Check Analysis.* A check analysis may be made by the purchaser or his representative from one or more gear blanks from each lot of 100 or fraction thereof ordered and this analysis shall conform to the requirements specified above. Sample for check analysis to be taken at the pitch line so that the blank will not be destroyed.

PHYSICAL PROPERTIES AND TESTS

4 *Hardness.* The hardness as shown by the scleroscope shall not be less than eighty, taken at the center of the top of the tooth after treatment.

5 *Treatment.* All gears, after the teeth are cut, shall be carbonized to a depth approximately one-sixth of the thickness of the teeth on the pitch line.

DIMENSIONS AND FINISH

(See Fig. 1)

6 *Diameter.* The outside diameter (A) over the teeth as machined must not vary from that specified by a more than plus zero (0) inch or minus one thirty-second (1/32) inch.

7 *Face.* (*a*) The face (B) of the gears must not vary from the specified width by more than plus one thirty-second (1/32) in. or minus one thirty-second (1/32) in.

(*b*) The minimum thickness of the rim (C) under the teeth shall be as follows, measured one-eighth (1/8) in. from the edge of the rim:

Pitch	Thickness of Rim
3	3/8 in.
2½	7/16 in.
2	½ in.

8 *Web.* The Web (D) of all gears shall have four $3^1/_2$ in. holes on $7^1/_4$ in. radius spaced with a tolerance of one-eighth (1/8) in. in center of webbed section, whenever the space will permit.

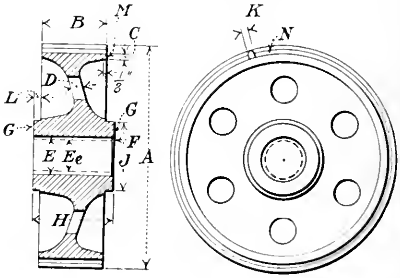

FIG. 1

9 *Bore.* (*a*) The diameter of finished bore (E) shall not vary from that specified by more than plus one-thousandth (0.001) in. or minus one and one-half thousandths (0.0015) in.

(*b*) The diameter of rough bore (Ee) shall not vary more than one-sixteenth (1/16) in. over or one-eight (1/8) under that specified.

(*c*) The ends of finished bores shall be chamfered (F) one-sixteenth (1/16) in. on motor side to avoid injury to shaft when mounting.

(*d*) Bore shall be measured with a pin gage or inside micrometer.

10 *Hub.* (*a*) The face (G) of hub (H), next to lining, shall have a smooth-bearing finish and run true with bore.

(*b*) The variation from the specified dimensions of hub (H) and hub extension (L) shall not exceed the following:

Length of hub (H) overall plus zero (0) in. to minus two-hundredths (0.02) in.
Length of hub extension (L) plus one thirty-second (1/32) in. to minus one thirty-second (1/32) in.
Diameter of hub extension (J) plus zero (O) in. to minus three hundredths (0.03) in.

11 *Teeth.* (*a*) The thickness (K) of teeth at the pitch line must be to specified dimensions as a maximum or to specified dimensions minus ten-thousandths (0.010) in. as a minimum.

(*b*) The teeth shall be of the Brown and Sharpe standard $14^1/_2$ degree involute form unless otherwise specified.

MARKING

12 *Marking.* The information indicated by the following list shall be plainly stamped on motor side of rim (N) of all gears; (*a*) Grade; (*b*) Month, (*c*) Year; (*d*) Serial Number of Manufacturer, (consecutive for each month); (*e*) Name, (initials or trade mark of manufacture).

INSPECTION AND REJECTION

13 *Inspection.* (*a*) All gears shall be tested for smooth running.

The teeth must be equally spaced so that the gear will run smoothly in both directions with a master pinion.

(*b*) Records of all chemical analysis and physical tests shall be kept by the manufacturer and shall be available to the purchaser for a period of one year.

14 *Rejection.* The purchaser should reserve the right to reject any portion of or all of the material which does not conform to the above specifications in every particular.

QUENCHED AND TEMPERED FORGED CARBON-STEEL GEARS

Manufacture

15 *Material.* All blanks for gears shall be made from open-hearth steel which has been thoroughly worked to secure a homogeneous dense material, free from all injurious defects.

Chemical Properties and Tests

16 *Chemical Properties.* The steel shall conform to the following requirements as to chemical composition.

Phosphorus	not over 0.05 per cent.
Sulphur	not over 0.05 per cent.

17 *Check Analysis.* A check analysis may be made by the purchaser or his representative from one or more gear blanks from each lot of 100 or fraction thereof ordered and this analysis shall conform to the requirements specified above. The sample for check analysis to be taken at the pitch line so that the blank will not be destroyed.

Dimensions and Finish

(See Fig. 1)

18 *Diameter.* The outside diameter (A) over the teeth as machined must not vary from that specified more than plus zero (0) in. or minus one thirty-second (1/32) in.

19 *Face.* (*a*) The face (B) of the gears must not vary from the specified width by more than plus one thirty-second (1/32) in. or minus one thirty-second (1/32) in.

(*b*) The minimum thickness of the rim (C) under the teeth shall be as follows, measured one-eighth (1/8) in. from the edge of the rim:

Pitch	Thickness of Rim
3	3/8 in.
2½	7/16 in.
2	½ in.

20 *Web.* The web (D) of all gears shall have four 3½ in. holes on 7¼ in. radius spaced with a tolerance of one-eighth (1/8) in. in center of webbed section, whenever the space will permit.

21 *Bore.* (*a*) The diameter of finished bore (E) shall not vary from that specified by more than plus one-thousandth (0.001) in. or minus one and one-half thousandths (0.0015) in.

(*b*) The diameter of rough bore (Ee) shall not vary more than one-sixteenth (1/16) in. over or one-eight (1/8) under that specified.

(*c*) The ends of finished bores shall be chamfered (F) one-sixteenth (1/16) in. on motor side to avoid injury to shaft when mounting.

(*d*) Bore shall be measured with a pin gauge or inside micrometer.

22 *Hub.* (*a*) The face (G) of hub (H) next to lining shall have a smooth-bearing finish and run true with bore.

(*b*) The variation from the specified dimensions of hub (H) and hub extension (L) shall not exceed the following:

Length of hub (H) overall plus zero (0) in. to minus two-hundredths (0.02) in.

Length of hub extension (L) plus one thirty-second (1/32) in. to minus one thirty-second (1/32) in.

Diameter of hub extension (J) plus zero (0) in. to minus three hundredths (0.03) in.

23 *Teeth.* (*a*) The thickness (K) of teeth at the pitch line must be to specified dimensions as a maximum or to specified dimensions minus ten-thousandths (0.010) in. as a minimum.

(*b*) The teeth shall be of the Brown and Sharpe standard 14½ degree involute form unless otherwise specified.

Marking

24 *Marking.* The information indicated by the following list shall be plainly stamped on motor side of rim (N) of all gears; (*a*) Grade; (*b*) Month; (*c*) Year; (*d*) Serial Number of Manufacturer, (consecutive for each month); (*e*) Name (initials or trade mark of manufacturer).

Inspection and Rejection

25 *Inspection.* (*a*) All gears shall be tested for smooth running. The teeth must be equally spaced so that the gear will run smoothly in both directions with a master pinion.

(*b*) Records of all chemical analysis and physical tests shall be kept by the manufacturer and shall be available to the purchaser for a period of one year.

26 *Rejection.* The purchaser reserves the right to reject any portion of or all of the material which does not conform to the above specifications in every particular.

CASE-HARDENED FORGED-STEEL PINIONS

Manufacture

27 *Material.* All blanks for pinions shall be made from open-hearth steel which has been thoroughly worked to secure a homogeneous dense material, free from all injurious defects.

Chemical Properties and Tests

28 *Chemical Properties.* The steel shall conform to the following requirements as to chemical composition.

Carbon.....0.20 per cent, not less than 0.12 per cent nor more than 0.28 per cent.
Manganese..0.50 per cent, not less than 0.40 per cent nor more than 0.60 per cent.
Phosphorus.....not over 0.05 per cent.
Sulphur........not over 0.05 per cent.

29 *Check Analysis.* A check analysis may be made by the purchaser or his representative from one or more pinion blanks from each lot of 100 or fraction thereof ordered and this analysis shall conform to the requirements specified above. The sample for check analysis to be taken at the pitch line so that the blank will not be destroyed.

Physical Properties and Tests

30 *Hardness.* The hardness as shown by the scleroscope shall not be less than eighty, taken at the center of the top of the tooth after treatment.

31 *Treatment.* All pinions, after the teeth are cut, shall be carbonized to a depth approximately one-sixth (1/6) of the thickness of the tooth on the pitch line.

Dimensions and Finish

(See Fig. 2)

32 *Diameter.* The outside diameter (A) of the pinion shall not vary from that specified by more than plus zero (0) in. or minus one thirty-second 1/32) in. measured at the center of the face.

33 *Face.* The face (B) of the pinion must not vary from the specified width by more than plus or minus one thirty-second (1/32) in.

34 *Bore.* All bores (C–E) must be finished after treatment. The diameter of the bore must be such that the standard plug gauge will not project less than one thirty-second (1/32) in. or more than one-sixteenth (1/16) in. measured at the large end of bore (C) and have bearing the full length of (D) of bore (C–E).

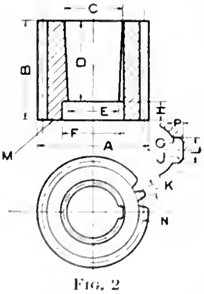

Fig. 2

35 *Counterbore.* (*a*) The depth (H) of the counterbore must not vary from that specified by more than plus zero (0) in. or minus one thirty-second (1/32) in.

(*b*) The diameter (F) of the counterbore must not vary from that specified by more than plus one thirty-second (1/32) in. or minus zero (0) in.

36 *Keyway.* (*a*) The sides (G) of the keyway must be cut parallel with the centerline of pinion.

(*b*) The width (L) of the keyway must not vary from that

specified by more than plus three thousandths (0.003) in. or minus zero (0) in.

(*c*) The depth (P) of the keyway must not vary from that specified by more than plus one sixty-fourth (1/64) in. or minus zero (0) in.

(*d*) The fillet (J) at the bottom of the keyway shall have one-sixteenth (1/16) in. radius. With this specification one-sixteenth (1/16) in. clearance shall be provided between bottom of keyway and pinion key.

37 *Teeth.* (*a*) The thickness (K) of teeth at the pitch line must be to specified dimensions as a maximum or to specified dimensions minus ten thousandths (0.010) in. as a minimum.

(*b*) The teeth shall be of Brown and Sharpe standard $14\frac{1}{2}$ degree involute form unless otherwise specified.

Marking

38 *Marking.* The information indicated by the following list shall be plainly stamped, preferably on the outer end (M), of pinions; (*a*) Grade; (*b*) Month, (*c*) Year, (*d*) Manufacturer's Serial Number (consecutive for each month), (*c*) Name (initials or trademark of manufacturer).

Inspection and Rejection

39 *Inspection.* (*a*) All pinions shall be tested for smooth running. The teeth must be equally spaced so that they will run smoothly in both directions with a master gear.

(*b*) All pinions shall be gaged with a standard taper plug gage, which shall be the same size as the nominal size of the bore at the large end.

(*c*) All pinions shall be free from any seams, cracks or other defects that would in any way affect their service.

40 *Rejection.* The purchaser should reserve the right to reject any portion of or all of the material, which does not conform to the above specifications in every particular.

QUENCHED AND TEMPERED FORGED CARBON-STEEL PINIONS

Manufacture

41 *Material.* All pinions shall be made from blanks of open-hearth steel which have been thoroughly worked to secure a homogeneous dense material, free from all injurious defects.

Chemical Properties and Tests

42 *Chemical Properties.* The steel shall conform to the following requirements as to chemical composition:

Phosphorus.....not over 0.05 per cent.
Sulphur........not over 0.05 per cent.

43 *Check Analysis.* A check analysis may be made by the purchaser or his representative from one or more pinion blanks from each lot of 100 or fraction thereof ordered and this analysis shall conform to the requirements specified above. The sample for check analysis to be taken at the pitch line so that the blank will not be destroyed.

Dimensions and Finish

(See Fig. 2)

44 *Diameter.* The outside diameter (A) of the pinion shall not vary from that specified by more than plus zero (0) inch. or minus one thirty-second (1/32) in. measured at the center of the face.

45 *Face.* The face (B) of the pinion must not vary from the specified width by more than plus or minus one thirty-second (1/32) in.

46 *Bore.* All bores (C–E) must be finished after treatment. The diameter of the bore must be such that the standard plug gage will not project less than one thirty-second (1/32) in. or more than one-sixteenth (1/16) in. measured at the large end of bore (C) and have bearing the full length of (D) of bore (C–E).

47 *Counterbore.* (*a*) The depth (H) of the counterbore must not vary from that specified by more than plus zero (0) in. or minus one thirty-second (1/32) in.

(*b*) The diameter (F) of the counterbore must not vary from that specified by more than plus one thirty-second (1/32) in. or minus zero (0) in.

48 *Keyway.* (*a*) The sides (G) of the keyway must be cut parallel with the centerline of pinion.

(*b*) The width (L) of the keyway must not vary from that specified by more than plus three thousandths (0.003) in. or minus zero (0) in.

(*c*) The depth (P) of the keyway must not vary from that specified by more than plus one sixty-fourth (1/64) in. or minus zero (0) in.

(*d*) The fillet (J) at the bottom of the keyway shall have one-sixteenth (1/16) in. radius. With this specification one-sixteenth (1/16) in. clearance shall be provided between bottom of keyway and pinion key.

49 *Teeth.* (*a*) The thickness (K) of teeth at the pitch line must be to specified dimensions as a maximum or to specified dimension minus ten thousandths (0.010) in. as a minimum.

(*b*) The teeth shall be of Brown and Sharpe standard $14\frac{1}{2}$ degree involute form unless otherwise specified.

Marking

50 *Marking.* The information indicated by the following list shall be plainly stamped, preferably on the outer end (M), of all pinions; (*a*) Grade; (*b*) Month; (*c*) Year; (*d*) Manufacturer, Serial Number of (consecutive for each month); (*e*) Name (initials or trademark of manufacturer).

Inspection and Rejection

51 *Inspection.* (*a*) All pinions shall be tested for smooth running. The teeth must be equally spaced so that they will run smoothly in both directions with a master gear.

(*b*) All pinions shall be gaged with a standard taper plug gage, which shall be the same size as the nominal size of the bore at the large end.

(*c*) All pinions shall be free from any seams, cracks or other defects that would in any way affect their service.

52 *Rejection.* The purchaser should reserve the right to reject any portion of or all of the material, which does not conform to the above specifications in every particular.

Gray-Iron Industrial Spur Gears

Dimensions

1 *Face.* The width of face for industrial spur gears shall be determined by dividing the diametral pitch into 10.

It is recommended that the values given in the following table be used as standard since they agree closely with those obtained by the formula.

Diametral Pitch	Face (In.)	Diametral Pitch	Face (In.)
1	10	4	2½
1¼	8	5	2
1½	7	6	1¾
1¾	6	7	1½
2	5	8	1¼
2¼	4½	10	1
2½	4	12	¾
2¾	3¾	14	¾
3	3½	16	⅝
3½	3	18	½
		20	½

2 *Rim.* The thickness of rim for spoked spur gears of gray iron for industrial work shall be determined by dividing the diametral pitch into 4, or by multiplying the circular pitch by 1.3.

Standard Specifications for Forged and Rolled Steels for Gears

The fifteen steels whose specifications are here proposed for adoption as standards for the gear industry cover the full range of requirements, since, with suitable modifications of heat treatment, it will not be found necessary to go outside this list to secure the physical properties that may be required in the manufacture of gears.

While the table gives all the essential information the following explanatory notes will serve to describe briefly the properties and special uses of the various steels. The specifications are in general similar to those prepared by the Society of Automotive Engineers.

The silicon in all cases is within the limits of 0.10 to 0.25 per cent, while the vanadium for the last three steels listed carries no upper limit. The desired amount is 0.18 per cent.

Where the open-hearth process is specified it is understood that the electric process is an acceptable alternative, but the reverse is not true.

STANDARD SPECIFICATIONS FOR ROLLED AND FORGED STEELS FOR GEARS

No.	Carbon	Manganese	Phosphorus	Sulphur	Nickel	Chrome	Vanadium	Process
								Open Hearth
1015	0.10-.20	0.30-.60	Max 0.045	Max 0.05				O. H.
1020	0.15-.25	0.30-.60	" 0.045	" 0.05				O. H.
1030	0.25-.35		" 0.045	" 0.05				O. H.
1046	0.40-.50	0.30-.50	" 0.045	" 0.05				O. H.
2315	0.10-.20	0.30-.60	" 0.04	" 0.045	3.25-3.75			O. H.
2345	0.40-.50	0.50-.80	" 0.04	" 0.045	3.25-3.75			O. H.

6145	0.40-.50	0.50-.80	" 0.04	" 0.04		0.80-1.10	0.15 min.	O. H.
6150	0.45-.55	0.50-.80	" 0.04	" 0.04		0.80-1.10	0.15 min.	O. H.

No. 1015 is a low-carbon machinery steel for use in the case-hardened state only, as it is too soft for durable gears unless carbonized. A combination of low carbon and low manganese in this steel also give a core too soft to support heavy loads unless the case is thick. This steel is intended for use particularly in gears of small light sections.

No. 1020 is a low-carbon machinery steel of good quality and low enough in carbon to case harden well. While this is one of the most widely used of gear steels, warning is given to users that a combination of carbon near the high limit and manganese also near the high limit gives a steel which is not desirable for case-hardening use in small cross sections. To avoid this danger, and as the carbon generally tends toward the upper limit, the previous steel No. 1015 is preferable for the small sections and No. 1020 for heavy sections.

No. 1030 is medium-carbon machinery steel of extra good quality, too high in carbon to be case hardened and intended primarily for use in its untreated state, so far as gear work is concerned. For pinions it is suitable to mate with cast-iron gears.

No. 1046 is machinery steel of high enough carbon to be satisfactorily hardened, yet not so high in carbon and manganese as to cause risk when water quenching. This is a development from and an improvement on S.A.E. No. 1045 for gear purposes.

No. 2315 is a low-carbon, 3½ per cent nickel steel for case hardening.

No. 2345 is a 3½ per cent nickel steel of high enough carbon to be hardened directly. This and its companion steel, No. 2315, are very widely known and need no comment.

No. 2350 is a similar 3½ per cent nickel steel with higher carbon, giving better hardening qualities on gears of heavy section. For light sections No. 2345 is preferable.

No. 3115 is a low-carbon chrome-nickel steel suitable for case hardening. It is cheaper and easier to machine than those which follow.

No. 3215 is medium-chrome-nickel steel suitable for case hardening.

No. 3245 is medium-chrome-nickel steel, the companion to the above, but with high enough carbon to harden directly. This is an excellent steel which has recently been adopted by the S.A.E. at the suggestion of the A.G.M.A.

No. 3312 is a high-chrome-nickel steel suitable for case hardening. It is peculiar in having no low limit on carbon, but practically the carbon runs 0.09 per cent at the lowest. Both this and its companion steel, No. 3340, are capable of very fine results, but require careful handling. Note that they are limited to the electrical process of manufacture, though, of course, no exception would be taken to the crucible process.

No. 3340 is a high-chrome-nickel steel similar to the above, but with carbon enough to harden directly. It is subject to the same comments.

No. 6120 is a low-carbon-chrome vanadium steel suitable for case hardening. In this and the two following the desired vanadium is 0.18 per cent, with no definite maximum, only the minimum being rigidly specified.

No. 6145 is similar steel, with carbon enough to harden directly, and recommended for light sections.

No. 6150 is a similar steel with 0.05 per cent more carbon, which enables it to be hardened to give somewhat higher physical properties, especially needed on gears of heavy section.

Standard Specifications for Steel Castings for Gears

For Steel Castings the Section Committee recommends the adoption of the specifications previously developed by the American Society for Testing Materials (A-27-21) with the following modifications:

(1) Paragraph 5 (a):—Add the sentence, "All gear castings must be properly annealed."

(2) Paragraphs 20 to 24 be omitted, as they apply only to ship and railway castings.

Class A castings under this specification are ordinary castings for which no physical requirements are specified. The great majority of gear castings fall in this class. These castings must, however, conform to the requirements of the following chemical composition:

Carbon	not over 0.30 per cent
Phosphorus by acid process	0.07 per cent
Phosphorus by basic process	0.06 per cent
Sulphur	not limited

Standard Specifications for Brass and Bronze for Gears

1 *Spur and Bevel Gears.* For Spur and Bevel Gears, hard-cast bronze, S.A.E. specification No. 62 of the well-known 88 copper-10 tin-2 zinc mixture to the following limits:

Copper	86 to 89 per cent
Tin	9 to 11 per cent
Zinc	1 to 3 per cent
Lead, max	0.20 per cent
Iron, max	0.06 per cent

Good castings made from this bronze should give the following minimum physical characteristics:

Ultimate strength	30,000 lb. per sq. in.
Yield point	15,000 lb. per sq. in.
Elongation in 2 in	14 per cent

2 *Worm Gears.* For Bronze Worm Gears, two alternative analyses of phosphor bronze, both S.A.E. specifications, Nos. 65 and 63, are recommended.

S.A.E. No. 65 (CALLED PHOSPHOR-GEAR BRONZE)

Copper	88 to 90 per cent
Tin	10 to 12 per cent
Phosphorus	0.1 to 0.3 per cent
Lead, zinc and impurities, max.	0.5 per cent

Good castings made of this alloy should give the following minimum characteristics:

Ultimate strength	35,000 lb. per sq. in.
Yield point	20,000 lb. per sq. in.
Elongation in 2 in	10 per cent

S.A.E. No. 63, CALLED LEADED GUN METAL

Copper	86 to 89 per cent
Tin	9 to 11 per cent
Lead	1 to 2.5 per cent
Phosphorus, max	0.25 per cent
Zinc and impurities, max	0.50 per cent

The following minimum physical characteristics may be expected from good castings of this alloy:

Ultimate strength	30,000 lb. per sq. in.
Yield point	12,000 lb. per sq. in.
Elongation in 2 in	10 per cent

3 *Bronze Bushings.* For Bronze Bushing the recommended practice is S.A.E. No. 64, a strong phosphor bronze with excellent anti-friction qualities, and capable of sustaining heavy loads and severe usage. The composition is as follows:

Copper	78.5 to 81.5 per cent
Tin	9. to 11. per cent
Lead	9. to 11. per cent
Phosphorus	0.05 to 0.25 per cent
Zinc, max	0.75 per cent
Other impurities, max	0.25 per cent

Good castings of this alloy should give the following minimum physical characteristics:

Ultimate strength	25,000 lb. per sq. in.
Yield point	12,000 lb. per sq. in.
Elongation in 2 in	8 per cent

Problems Encountered in the Design of High-Pressure Machinery

THE term "high-pressure" is merely a relative one, and as manufacturing processes progress and the methods of handling become more familiar, undoubtedly pressures will increase and the word "high" in this connection become less significant. Two generations ago one hundred pounds steam pressure was relatively high, but as soon as designers and users mastered the problems of higher pressures, the pressures of that day became insignificant.

No doubt as design of apparatus to produce pressure, material, and methods for handling pressure improve, we shall see higher pressures. The present generation of engineers have seen pressures of a thousand pounds, which early in their experience seemed high, placed in the obsolete class, and pressures of two to four thousand pounds are beginning to lose importance on account of improved designs and familiarity with handling.

Pressures of fifteen thousand pounds are now produced and used, but it should not be inferred that any pressure near that amount will become general, for it could not be applied except in special instances; but with the design of apparatus to produce this pressure successfully and the selection of material to handle it safely, many of the pressures now used will lose their designation as "high."

The pressures and problems referred to are some of those encountered in compressing gases for manufacturing and industrial purposes, and in speaking of gases the term is used broadly and intended to include air, oxygen, hydrogen, acetylene, carbonic acid gas, nitrous oxide, ammonia, sulphur dioxide, helium and mixtures of gases.

There are, however, pressures which are still high and which present complex problems to both designer and user, problems in which the character of the gas figures most prominently in designing pressure-producing apparatus and at present controls the pressures within certain limits. In some cases excessive pressures accompanied by sufficient changes in temperature will alter the condition of the gas. The ultimate use of the gas often controls the pressure and design.

In some instances the pressure must be produced without an appreciable increase in temperature, in others the temperature does not figure so prominently, while in still others increases in temperature are necessary during the production of pressure.

The gas itself is a determining factor, for even before design in regard to volumes and pressure, in many instances materials must be considered. Materials which can be used when handling one gas with perfect safety may in the presence of another gas and even at a lower pressure form an extremely explosive compound. Metals that serve satisfactorily in the handling of heavy and dense gases may not be sufficiently close-grained to handle light gases. Sometimes metals cannot be used at all. Where neither of two gases will corrode ordinary materials, sometimes their mixture in certain proportions, even though it is physical and not chemical, will in a comparatively short time ruin anything except special materials.

New combinations of gases are appearing and old combinations which heretofore have not been generally employed have been made available for new uses through the proper design of high-pressure machinery and materials.

The power problem enters prominently, for some gases, like some materials, are very much heavier than others, the heavier gases requiring more power than the light ones, all other conditions being equal.

The leakage of gas during compression and handling also influences the kind of power selected and its application. Some gases when mixed with air will make an explosive mixture and engine-room conditions then become dangerous. Leakage is also dependent to some extent on the lightness of the gas. A light gas will leak faster than a heavy one, and precautions in design must be taken as this leakage might prove a financial loss for certain gases are quite costly.

Lubrication of the compressor is very important, not only in amount but as regards quality and place of injection. In some instances too much lubricant or poor quality causes trouble in the compressor or pipe line. One gas requires a lubricant with water at its base, for if oil were used it would explode. With another gas, which ordinarily would not be affected by oil, a water lubricant must be used on account of the use of the gas after compression. There are gases where no lubricant is required, the gas itself containing sufficient lubricant, while other gases absorb some kinds of lubricant and their subsequent efficiency is impaired. A lubricant may combine with a gas during compression and entirely change the gas. In still another case the ultimate use of the gas determines the lubricant, for ordinary oil would make the gas unfit for use.

After considering the gas, its physical and chemical properties, and the pressures to which it can be safely compressed, the volume to be handled in individual units must be determined. There may be gases which can be handled to high pressures safely in comparatively small volumes, which in large volumes might cause trouble.

The purity of gas entering the compressor is important. Certain gases if pure are safe to compress, but if polluted with other gases may not be dangerous at atmospheric pressure but will explode when compressed. Two gases which when combined in a certain way form part of our bodies and food, when combined in another way will burn steel, and in still another way, though harmless, at atmospheric pressure and temperature, cannot be compressed together without a frightful explosion resulting.

The pressure of the gas at the intake of the compressor is extremely important, for this very materially influences the design of the compressor and is also an important item in determining the power required. Atmospheric pressures varying according to altitude change the design of a compressor often very radically, especially if the final pressure is high.

The particular use of the gas under pressure, whether it is to be used at a constant pressure through comparatively wide limits, or whether the pressure is to be built up from the intake to a certain definite pressure, materially influences the design. Certain features of design are affected if the compressor is to stop and start again during the building up of pressure in the line, particularly if no gas is to be lost. Varying capacities but at constant pressure and varying pressures with varying capacities also require special attention. The nature of the power available or most convenient sometimes changes the whole design. Location of compressor and transportation facilities have been known to control design.

The foregoing are by no means all of the problems existing, and no doubt as new uses for gases are devised new problems will present themselves.

Ebenezer Hill.

The South—A Field for Great Engineering Development

IN Mr. Adsit's paper on Power Development in the Southeast, printed in this issue of Mechanical Engineering, the author takes occasion to emphasize the dependability of the water power of the South. He further states that the resources are available for ample provision of power for the growing industries of that section. In another paper in this issue Mr. F. H. Neely treats of the desirable characteristics of southern labor.

These two statements regarding fundamentals for sound industrial development have led us to look farther into the present status of the South in industry and to ascertain something of its natural resources. Space does not permit a tabulation of facts, but a few statements that show trends will undoubtedly be of interest.

In 1920, nearly one-sixth of the manufactures of the country were produced in the South. In the same year nearly one-half of the active cotton spindles and three sevenths of the active cotton looms were in southern mills and five-eighths of the cotton used in the country was processed in these mills. One-ninth of the country's pig iron and one-half of the lumber came from the South.

We find that all of the bauxite, turpentine and resin of the country is in the limits of the southern states. They also have 60 per cent of the natural gas, 50 per cent of the lumber, 45 per cent of the lead, 42 per cent of the zinc, 30 per cent of the lime, 26 per cent of the coal and 10 per cent of the iron ore.

Furthermore, and contrary to general understanding, there is a large section of the South at an elevation of about 1000 ft. above sea level with a pleasant climate and reasonably constant temperature.

All of the foregoing point to an industrial future for the South which is of great interest to the entire country, for the prosperity and industrial activity of a country must be well distributed to insure the prosperity of the nation. This industrial future must be of even greater import to the engineering profession and especially to the mechanical engineer, the "engineer of industry."

The holding of the Spring Meeting of The American Society of Mechanical Engineers in Atlanta this year will therefore be of great value, not only in stimulating engineering interest in the South but in setting up a contact between southern engineers and those of the rest of the country.

Recognition of Independent Status of the British Royal Air Force

AS the result of a discussion on March 16, 1922, in the House of Commons, the status of the Royal Air Force with respect to the other branches of the British War Establishment has been defined. According to a statement by Mr. Austen Chamberlain as leader of the House, the Government has arrived at the following conclusions:

First, That the Air Force must be autonomous in matters of administration and education.

Second, That in the case of defense against air raids the Army and Navy must play a secondary role.

Third, That in the case of military operations by land or naval operations by sea, the Air Force must be in strict subordination to the general or admiral in supreme command.

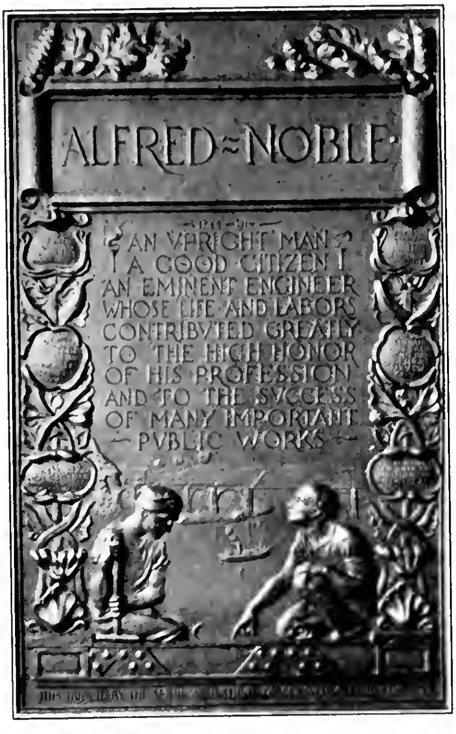
Fourth, That in other cases, such as protection of commerce and attacks on enemy harbors and inland towns, the relations between the Air Force and the other Services shall be regarded rather as a matter of coöperation than of the strict subordination which is necessary when airplanes are acting merely as auxiliaries to other arms.

Lastly, the Government has decided to appoint a committee to examine carefully into the system of naval and air coöperation and to advise how best to insure that the Air Force be enabled to render to the Navy, and also to the other Services, the aid that they may require.

For Great Britain this means definitely that the Royal Air Force becomes henceforth the first line of defense, for obviously the only possible means of attack on the British Isles is by air. The decision of the Government in this connection is in many respects revolutionary, as it subordinates old-established and immensely wealthy services to what is practically a newcomer in the field. Its importance, however, should not be exaggerated, because while the Royal Air Force has been given such prominent tasks to perform, its whole budget barely equals the cost of two capital ships under present conditions.

Alfred Noble Memorial Tablet Unveiled

Impressive addresses marked the unveiling of the Alfred Noble Memorial Tablet in the Engineering Societies Building, New York City, on the afternoon of Wednesday, March 15. The tablet was presented by the American Institute of Consulting Engineers. The American Society of Mechanical Engineers together with the other national engineering societies joined in the tribute to Mr. Noble who had held office in the A.S.M.E. and several of the professional societies, and was a recipient of the John Fritz Medal awarded for achievement in engineering work.



Alfred Noble Memorial Tablet

The ceremonies took place in the entrance hall of the Engineering Societies Building, where the tablet has been placed. Charles Wellford Leavitt, chairman of the Alfred Noble Memorial Committee, delivered the principal address; Dr. Alexander C. Humphreys, president of the American Institute of Consulting Engineers, presented the custody of the tablet to the United Engineering Society, and J. Vipond Davies accepted the tablet, the work of Willard Paddock, on behalf of the Board of Trustees of the United Engineering Society.

Mr. Noble became a member of The American Society of Mechanical Engineers in 1907. From 1912 to 1916 he was one of the managers of the Society, and for the year 1913–1914 he was a member of the Executive Committee of the Society's Council.

The tablet contains this inscription:

"Alfred Noble, 1844–1914. An Upright Man, A Good Citizen, An Eminent Engineer, Whose Life and Labors Contributed Greatly to the High Honor of His Profession and to the Success of Many Important Public Works."

The more important of Mr. Noble's public services are outlined

on the tablet which lists his work from 1904 to 1909 as engineer of the Pennsylvania Tunnels, East River Division, and his services in 1895 with the Nicaragua Canal Commission. Other feats of Mr. Noble's included are his work from 1897–1899 with the U. S. Board of Deep Water Ways; 1872–1882 as engineer of the construction locks at St. Ste. Marie; 1909–1914, consulting engineer of the Catskill aqueduct; Pearl Harbor dry dock in Hawaii; 1899 to 1902, Isthmian Canal Commission; and as resident engineer on the Washington, Memphis and Cairo bridges from 1872 to 1882 He served in the Iron Brigade as a United States soldier from 1861 to 1865.

Edwin Allen Fessenden Accepts Professorship at Rensselaer Polytechnic Institute

Announcement has been made by the Rensselaer Polytechnic Institute that Prof. Edwin A. Fessenden of Pennsylvania State College will become, at the beginning of the next collegiate year, professor and head of its department of mechanical engineering.

Professor Fessenden was born 40 years ago in Butler County, Ohio, but spent his boyhood in St. Louis, Mo. where he attended the St. Louis Manual Training School. Later he entered Washington University and then the University of Missouri, securing at the latter institution the degree of bachelor of science in mechanical engineering in 1906 and two years following, the degree of mechanical engineer. From 1905 to 1907 he was an instructor in mechanical engineering in the University of Missouri and for the next nine years served there as assistant professor and associate professor of mechanical engineering. For one and a half years of this latter period he was in charge of the department of mechanical engineering and also served for a similar period as Acting Dean of the School of Engineering and Director of the Engineering Experiment Station.

From 1916 to the present he has been professor of mechanical engineering and head of the department at Pennsylvania State College and during the last two years has designed and constructed a new mechanical-engineering laboratory for this institution.

His research work at the University of Missouri Engineering Experiment Station included the study of coal weathering and heat transfer in boilers, while he has been the author of various articles in engineering journals, papers and discussions in the proceedings of the A.S.M.E., American Society of Refrigerating Engineers, and Society for the Promotion of Engineering Education, as well as bulletins of the Engineering Experiment Station of the University of Missouri.

Professor Fessenden was elected to full membership in the Society in 1914. He is also a member of the Society for the Promotion of Engineering Education, Sigma Xi, Tau Beta Pi, Sigma Tau and Alpha Tau Omega. He will undertake his new duties in the Fall when the present incumbent of the position, Dr. A. M. Greene, Jr., becomes Dean of Engineering at Princeton University.

Tufts College Giving Lectures by Radio

Probably the first instance of an American college giving instruction by radio is the course of fifteen lectures prepared by the faculty of Tufts College and being broadcasted by the American Radio & Research Corp. from its station at Medford Hill, Mass., twice a week beginning April 6 and concluding May 27.

By tuning the wireless telephone receiving instrument to 360 meter wave length and listening for signal WGI, these lectures, which cover a variety of topics, can be heard any Monday or Saturday evening.

The Word "Symposium" Misused

To the Editor:

I notice that your Society uses the word "symposium" very frequently to indicate a series of meetings to discuss some particular section of our activities, but I think that, if you looked up the meaning of the word, you will agree with me that it is hardly suitable for a "—— country."

Daniel Adamson.

Hyde, Cheshire, England.

Henry Hess, Former A.S.M.E. Officer, Dies

Mr. Henry Hess, Past Vice-President of The American Society of Mechanical Engineers, died at his home in Atlantic City on March 23, 1922. He had been in failing health for the past two years but had been so much improved that he had visited his office in Philadelphia several days before his death.

Henry Hess

Henry Hess was born in Darmstädt, Germany, in March, 1864, and came to the United States when a small boy. His education was received in the New York schools, and was supplemented by several years of additional schooling in Germany. After his return to the United States he was employed at the Watervliet Arsenal, Troy, N. Y., and later at the Niles Tool Works, Hamilton, Ohio. While in the employ of the latter concern he was sent to Germany to erect the German Niles Tool Works at Oberschoeneweide, near Berlin. He remained to have charge of the operation of this plant for two years after its erection. Upon his return to the United States in 1902 he organized the Hess-Bright Manufacturing Co. In 1912 he sold his interests in this company and organized the Hess Steel Corporation of Baltimore, with which organization he was connected at the time of his death.

Mr. Hess became a member of The American Society of Mechanical Engineers in 1906. From 1911 to 1914 he served the Society as Manager, and from 1914 to 1916 as Vice-President. In 1915 he presented to the Society a gift of $2000, the income from which is given annually as the Junior and Student Prizes for the best technical papers by Junior and Student Members. Mr. Hess was past-president of both the Society of Automotive Engineers and of the Philadelphia Engineers' Club; he was a member of the American Institute of Mining Engineers, the American Society for Testing Materials, the American Iron and Steel Institute, the American Electrochemical Society, the American Academy of Political and Social Science, The Franklin Institute, the New York Engineers' Club, the Art Club of Philadelphia and the Economics Club.

During his lifetime Mr. Hess was a contributor to various technical publications. He was a special lecturer at Columbia University on subjects on which he was an authority. Of late years he had been greatly interested in color photography and had lectured on this subject before various organizations.

Mr. Hess is survived by his wife, two daughters and a son, Mr. H. Lawrence Hess of Philadelphia, a member of the Society.

Industrial Teachers' Scholarships for New Yorkers

Within the near future the University of the State of New York will award twenty-five scholarships to qualified trade and technically trained men who desire to prepare themselves for teaching. Each person selected for a scholarship will receive at least $1000 for one school, year period and be required to attend for ten months the Industrial Teacher Training Department of the State Normal School at Buffalo. Upon satisfactory completion of this training course the scholarship holder will be licensed for life to teach his specific occupation in the vocational schools of the state, and under the present schedule will be paid a salary ranging from $1800 to $3500 per annum. The Director of Vocational and Extension Education, State Department of Education, Albany, N. Y. will furnish detailed information and application blanks upon request.

William Newton Best Dies

William Newton Best, one of the very well-known members of the Society in the field of liquid-fuel burning, died in Brooklyn on April 11, 1922. Mr. Best was born at Clayton, near Quincy, Illinois, on June 3, 1860, and attended the public schools there and the Gem City Business College. He then went into railroad work and continued in various capacities until 1901, when he resigned his position as superintendent on the Los Angeles and Salt Lake Railroad to begin the manufacture of his own inventions. At the time of his death he had U. S. letters patent covering forty-four devices, most of them relatting to the oil-burning industry, and was president and consulting engineer of the W. N. Best Furnace and Burner Corporation at 11 Broadway, New York.

William Newton Best

Dr. Best was the author of the book Science of Burning Liquid Fuel, and in 1917 the honorary degree of Doctor of Science was conferred on him by the Lincoln Memorial University, Cumberland Gap, Tenn., of which he was for some time a member of the Board of Trustees.

He became a member of the A.S.M.E. in 1912; he was one of the committee appointed in 1918 to revise its Boiler Test Code, and served for some time as its representative on the Board of the Engineering Societies Library. He was also a Fellow of the Royal Society of Arts, London, and a member of the American Institute of Mining and Metallurgical Engineers, the American Institute of Metals, the International Railway Fuel Association, American Railway Master Mechanic's Association, The Franklin Institute, the Aero Society of America and of the New York Academy of Sciences.

He was also a member of the Long Island Lodge 382 F. and A. M., vice-president of the Board of Directors of the Goodwill Industries of Brooklyn, Inc., vice-president of the Board of the Williamsburgh Rescue Mission, Inc., and a member of the Board of Governors of the Neponsit Club of Long Island.

Dr. Best will be missed by a host of friends, as well as in the many activities in which he was interested.

Meeting of the Taylor Society

One of the best-balanced and most successful meetings that the Taylor Society has ever held took place at the City Club, Philadelphia, March 16 to 18. The City Club and the Engineers' Club of Philadelphia extended guest privileges to both members and guests and approximately 450 were in attendance.

At the opening session on Thursday morning Dr. H. S. Person, Managing Director of the Society, presided and John M. Holcombe, Jr., manager Sales Research Division, Phoenix Mutual Life Insurance Company, Hartford, Conn., read a paper entitled A Case of Sales Research. Studies in territory analysis, the selection of salesmen, rating scales, personal-history blanks, and in general somewhat the same system of investigation used for classifying their risks was outlined as applied to the sales force.

In the afternoon, with Richard A. Feiss, President of the Society, in the chair, The Problem of the Chief Executive was presented by Henry P. Kendall, of Boston. Mr. Kendall's position as one of our younger captains of industry who has developed scientific management in one plant after another in accordance with a consistent policy for a number of years, lent additional interest to his paper. On Friday Mrs. L. M. Gilbreth, due to Mr. Gilbreth's absence abroad, read a paper on Super-Standards which won much approval. The general use of the title word was deplored as limiting, since the super-standard of today is the standard of tomorrow. At the afternoon session George E. Frazer of Frazer and Torbet, Chicago, read a paper on Budget Control in which the necessity in industry for coöperation on financial considerations throughout the departments was emphasized.

The current series of articles in the *Atlantic Monthly* by Arthur Pound attracted particular attention to his address, which he entitled Mills and Minds. His statement that the industrial problem of today is that of labor rather than material and that the principles of psychology should be applied to industrial management, was most favorably received.

The closing session was devoted to two papers in the field of operating technique. The first, by Percy S. Brown, works manager of the Corona Typewriter Company, was called String-Board Graphics, and described an effective method of this type of control at his plant. The second, The Work of the Balance-of-Materials Clerk, by Thomas W. Mitchell, management engineer, Philadelphia, described the standard Taylor method in the particular field considered, and was the first of a series which he is preparing on standard Taylor practice.

Power Show to Follow 1922 Annual Meeting

The tentative program for the 1922 A.S.M.E. Annual Meeting calls for a Session of the Fuels Division on Wednesday, December 6, and a session of the Power Division on Thursday morning December 7. At noon on Thursday the Exposition of Power and Mechanical Engineering will be opened in the Grand Central Palace. This exposition will include apparatus employed in the generation, distribution and use of power. The managers of the show have had considerable experience in the conduct of various chemical, flower and automobile shows, in which they have been successful in developing large, highly educational exhibitions of proven value to technicians and industries.

An advisory committee has been appointed to assist in determining the policies of the exposition. This committee includes the names of the presidents of The American Society of Mechanical Engineers, The National Electric Light Association, and the National Association of Stationary Engineers.

"Luminaire"—a Good Substitute for a Bad Combination

The coming into vogue of appliances which can be removed from place to place and to which the misnomer "movable fixtures" has been attached has brought the matter particularly to the attention of the lighting people. The Illuminating Engineering Society referred the consideration of this question to its Committee on Nomenclature and Standards with the suggestion that a term be recommended. Requests for suggestions of suitable terms were sent out to the membership of the Society and a considerable number of such suggestions were received. It was found, however, that most of the terms proposed were manufactured or coined words which had no legitimate ancestry and were therefore objectionable. Among the terms suggested, however, was one which met with the approval of the Committee; namely, the word "luminaire." This word is used in this connection in the French language. Its construction and ancestry are such that it can be adopted into the English language as readily as "garage," "hangar," etc., which have recently been taken in. The significance of the word is evident on the face of it. It is believed that this word could and should be introduced into the English language and that it would be a distinct advantage so to do.

The Committee on Nomenclature and Standards recommended the use of this generic term for "lighting unit" in its report as presented to the annual convention of the Society at Rochester last September.

The Council of the Illuminating Engineering Society at the March meeting formally approved and adopted the use of the word "luminaire."

An expression of opinion favorable to the adoption of this term has been received from Engineering Societies and other organizations.

Engineering and Industrial Standardization

Agreement Near on Machine-Screw-Thread Standardization in This Country

FOR the past eight months the Sectional Committee on the Standardization and Unification of Screw Threads, Luther D. Burlingame, Chairman, has been making a careful review of the Progress Report of the National Screw Thread Commission published in the Spring of 1921. The Working Sub-Committee of seven, to which the detailed study was assigned, reported its findings to the Section Committee on March 15. This report is in the form of a working manual on the American machine-screw thread and is based entirely on the N.S.T.C. Report. It omits, however, all reference to the loose fit, pipe thread, methods of gaging, and fire-hose couplings, all of which are treated by the Commission.

The Sectional Committee examined this manual very thoroughly, and after making numerous suggestions referred it for final revision to a special committee consisting of Messrs. Elwood Burdsall, Ralph E. Flanders, and Earle Buckingham. The Sectional Committee also instructed Messrs. Wells, Ehrman, Flanders, and Buckingham, who are members of the N.S.T.C. as well as members of the Sectional Committee, to confer informally with the Commission on certain points. This was done on March 17 in Washington at a regularly called meeting. The results of this informal conference were very satisfactory to all concerned. Within a very short time, therefore, American screw-thread practice will be completely unified on paper at least, and a working manual will be ready for printing and distribution. All those interested in securing copies of this manual are requested to communicate with the Secretary to the Committee, C. B. LePage, 29 West 39th Street, New York.

Building Construction and Standardization

It has been estimated that the suspension of building during the war has produced a national shortage of dwelling houses of close on to a million, and due to high costs post-war building operations have been too limited to bring about any material change in the situation.

Herbert Hoover, Secretary of the Department of Commerce, has given this problem some attention during the past few months and is devoting the resources of his department to its solution. It is his opinion, however, that on each community rests the responsibility of solving its housing problem. He holds that we are, or should be, a country of local community action and that the province of the Federal Government is to stimulate and assist local action.

Each local community must in a large measure solve its housing problem since the three principal factors entering into it have, at present at least, large local significance. Cost of materials, cost of labor, and available home-building capital are of necessity different in the various localities. If the local community develops its own resources in each of these items, high railroad rates need not be considered.

In this activity the Department of Commerce is working through a broadly representative central Building Code Committee with Dr. Ira H. Woolson as its chairman. Its first effort was to bring about local conferences on the housing situation in the different cities with a view to ameliorating conditions. These conferences have been held in over one hundred cities with the coöperation of many unofficial bodies. The latter comprised chambers of commerce, labor organizations, building and other trade associations, bankers, material manufacturers, and contractors. Through these conferences and through other forms of local initiative a very considerable amount of good has been accomplished, although the results have varied a great deal between cities. Positive plans have been worked out in many of them and great stimulation to home building has ensued. Where they have gone upon the rocks it has been due to corrupt conditions of the building trades or to wage questions.

The Building Code Committee has, in addition to its local effort, created a number of agencies for the purpose of securing constructive solution to some of the more general problems. Various special committees have been formed and are engaged in sincere efforts in the following fields: Standardization of Contractor's Specifications; Simplification of Plumbing Requirements and Practice; Standardization of Clay Products, Lighting Fixtures, Lumber, Paint and Varnish and Standardization of the elements in House Design. These efforts at standardization and simplification are directed against the high cost of material; it is hoped, however, that they will also have their effect in reducing the labor cost of buildings.

The Committee on Plumbing Specifications is making good progress and is directing a considerable amount of experimental work which is being carried on at the Bureau of Standards. It, as well as the general committee, is also in close touch with the American Engineering Standards Committee, through which they receive the support and assistance of its member-bodies.

Bolt, Nut and Rivet Proportions

On Thursday, March 16, the Sectional Committee on Bolt, Nut and Rivet Proportions held its organization meeting in New York. Though the personnel of this Sectional Committee is not yet complete, 23 of its members attended this meeting. The manufacturers were represented by 12, the Consumers by 9, and the General Interests by 2. The Consumers' group consisted of representatives of nine societies and associations.

After attending to certain organization matters the scope of the committee's work was informally but very fully discussed. As a result of which, it was decided to divide the field into seven more or less distinct parts. Through the medium of a special Committee on Committees the personnel of the corresponding seven sub-committees was tentatively determined and, in the afternoon following the meeting of the Sectional Committee, four of these Sub-Committees organized and made plans for the preliminary collection of data and information. The names of the seven Sub-Committees with their officers are given below.

1 *Sub-Committee on Large and Small Rivets*
    G. W. NELSON, *Chairman*
    F. W. FRITCHEY, *Secretary.*
2 *Sub-Committee on Wrench Heads and Nuts*
    G. F. JENKS, *Chairman* and *Secretary.*
3 *Sub-Committee on Slotted Heads*
    E. WINSOR REED, *Chairman*
    E. M. WHITING, *Secretary.*
4 *Sub-Committee on Track Bolts*
5 *Sub-Committee on Carriage Bolts*
6 *Sub-Committee on Special Bolts and Nuts for Agricultural Machinery*
    E. P. STAHL, *Chairman.*
7 *Sub-Committee on Body Dimensions and Material*
    S. F. NEWMAN, *Chairman.*

Code for Electricity Meters

The National Electric Light Association and the Association of Edison Illuminating Companies have submitted to the American Engineering Standards Committee for approval as American Standard the Code for Electricity Meters, known as the "Meter Code."

Nine of the ten sections of the present code were prepared in 1912 by a joint committee of the two associations and representatives from the Electrical Testing Laboratories, from the leading meter-manufacturing companies and from public-service commissions and other regulatory bodies organized for the purpose of supervising electric service.

The code contains a tenth section, Parts A, B, and C of which were brought out in 1916 and Parts D and E in 1920. The organizations presenting the code for approval state that it represents in crystallized form standard American meter practice as nearly as it has been possible to determine it by impartial consideration and criticism.

The American Engineering Standards Committee would be very glad to learn from those interested of the extent to which they make use of this Standard and this Code. It desires also to receive any other information regarding the code in meeting the needs of the industry.

LIBRARY NOTES AND BOOK REVIEWS

Library in Need of Proceedings

The Engineering Societies Library requires the Proceedings of the American Railway Engineering Association for 1918, 1919 and 1920 to complete its file, but due to the fact that these issues are out of print it has been unsuccessful in securing them through the regular channels.

Any member of the Society having these copies and presenting them to the Library, would be coöperating in the proper preservation of engineering records for reference use and the benefit of the profession.

Work of Recataloging Engineering Library Steadily Progressing

Members of the Society will be interested to learn that the work of recataloging the vast number of volumes composing the Engineering Societies Library is progressing so well that to date about 65 per cent has been completed. This means that since the task was started in July, 1919, 52,111 volumes, representing 14,745 titles, have been cataloged; 33,513 subjects have been made available and author entries for all books have been added to the catalog while 103,809 cards have been filed.

The great care and accuracy required in compiling a catalog of books is beyond the comprehension of most persons unfamiliar with such work. A catalog is not merely a list of books. Unless it discloses the purpose of each book and reveals its contents in such a way as to inform the research worker, it is not presenting the resources of the library. It must be made with both the reader and the book in mind and should be so suggestive as to lead the man to all available references. The catalog cannot be an exhaustive index but rather it is a sign board to point the way to detailed material which the reader can follow up and exhaust for himself. The proposed catalog of the Engineering Societies Library, through its detailed subject index, will reveal much more specific references than would be possible in any other type of catalog.

In the preparation of the catalog, the books must first be classified and book classification is a science. Under the subject of railroads, for example, it is not enough to know that there are books on locomotives, terminal stations, signals, road beds, rolling stock, etc., but the classifier must first realize that the two main divisions of this subject are the engineering or construction and the transportation and economy, and that the literature on the subject will naturally fall into one of these groups. By the use of classification charts the limitations of groups are clearly defined, important points that it is necessary to keep in mind when analyzing the books are determined, and a sensible general guide established.

The next step is to decide the correct subject of each book, not simply by the title page, but through a careful perusal of the text. One book can stand in only one place on the shelves, but the same book can appear in any number of places in the catalog, and the great advantage of a catalog which gives an analysis of a book from all angles must be developed to the highest degree.

Then follows indexing under authors and perhaps contributing editors, and finally the assignment of a symbol by which it can be identified. A record of these symbols is kept, together with the author and title they represent, and it serves as an inventory of the books as they stand on the shelves.

The whole undertaking requires the most careful and painstaking work, with each book being handled from fifteen to twenty times after its receipt from the publishers until it is placed on the shelves. However, the results justify the time, labor and funds expended. With less than three-quarters of the books completely analyzed, it has been found that the efficiency of the library has increased in amazing proportions, as is apparent to the members of the library staff who daily answer many inquiries covering a great variety of subjects.

Book Notes

Aggregation and Flow of Solids. By Sir George Beilby. Macmillan and Co., Ltd., London, 1921. Cloth, 6×9 in., 256 pp., illustrated with plates, 20s.

The molecular structure and physical properties of matter in the solid state have engaged the author's attention for many years, and from time to time papers embodying the results from particular researches have been published. The entire series of investigations has now been collected and sifted, and the results appear in the present volumes as a consecutive whole. The book is an interesting record of actual experimental observations, many of which have important industrial applications, and a summary of the conclusions reached by the author as to the meaning of the phenomena observed. A large number of excellent photomicrographs are included.

Blue Printing and Modern Plan Copying. By B. J. Hall. Sir Isaac Pitman & Sons, Ltd., New York, 1921. Cloth, 5 × 8 in., 130 pp., illus., $2.

Of interest to engineers who have plans to be copied, to installers of copying plants and to operators. The first section of the book discusses the capabilities of contact photography and allied processes for copying drawings, as well as the proper preparation of drawings for reproduction. Section two describes the machinery and apparatus used in blueprinting plants. The concluding section deals with the layout of blueprinting rooms and methods of working. The treatment includes both contact and camera processes.

Cotton Facts. Compiled and edited by Alfred B. Shepperson. Revised and enlarged by C. W. Shepperson. Shepperson Publishing Co., New York, 1921. Cloth, 4 × 7 in., 180 pp., portraits, map.

A convenient compilation of commercial and financial information required by those engaged in the cotton industry, which has appeared annually for forty-six years.

Descriptive Geometry. By George Young and H. E. Baxter. The Macmillan Co., New York, 1921. Cloth, 5 × 8 in., 310 pp., diagrams, $3.25.

Believing that the chief value of descriptive geometry lies in its imaginative quality, these authors present it so as to develop the imagination; and therefore they encourage intuitive rather than rigidly formal methods. The treatment has been kept purely abstract, in order to avoid the tendency of the subject to degenerate into practical rules and formulas; introductory matter showing the relation of the principles under discussion to structural work is provided, and exercises to show the application of the abstract ideas to concrete, practical problems are included.

Distribution of Gas. By Walter Hole. Fourth edition. Benn Brothers, Ltd., London, 1921. Cloth, 7×10 in., 699 pp., illustrated with diagrams, 50s.

This book is uniform in size with Mead's Modern Gasworks Practice, to which it forms a fitting companion. That work treats of gas manufacture; this takes up the account at the gas holder and discusses the distribution to the consumers' appliances. The scope of the volume is a wide one. The opening chapter discusses the rights and duties of gas undertakings. Succeeding chapters treat of discharges from pipes, station governors, districting, pipes and joints of iron and steel, mainlaying, valves and cocks, conduits, service pipes, meters, internal fitting, internal lighting, gas stoves and heaters, gas engines, industrial uses of gas, pressures, complaints and repairs, street lighting, high-pressure distribution, high-pressure lighting and heating, leakage, electrolysis and fusion. The information given is thoroughly representative of current practice. All obsolete matter has been deleted in preparing this new edition and much that is new in connection with this work has been added.

Dynamic and Static Balancing. By Edward K. Hammond. First edition. Industrial Press, New York, 1921. Paper, 6×8 in., 58 pp., illus., $0.50.

A discussion of the principles of balancing, with a description of machines and methods, written in simple language. Intended for shopmen. Avoids mathematical theory.

Die Eisenkonstruktionen. By L. Geusen. Third edition, revised. Julius Springer, Berlin, 1921. Cloth, 8×11 in., 282 pp., diagrams, tables, 384 marks.

This textbook for students of structural engineering is divided into three sections, treating respectively of the principles, of steel buildings, and of bridges. By this arrangement the general rules and methods governing steel structures are taught first and emphasized by suitable problems, taken from practice. The application of these methods in framing buildings and bridges is considered in the later sections. The text is concise and illustrated by numerous drawings. An appendix contains the necessary tables of the properties of structural shapes.

Die Wasserversorgung der Staedte. By O. Smreker. Fifth edition. Wilhelm Engelmann, Leipsig, 1914. Cloth, 7×10 in., 522 pp., illus., diagrams, tables, 57 Marks.

This work forms the third of the twelve volumes upon hydraulic engineering which constitute the third section of the Handbuch der Ingenieurwissenschaften, and is concerned with municipal water supplies. The present edition has been thoroughly revised, both with respect to arrangement and contents. The arrangement follows the course of operations used in securing a water supply, discussing first the preliminary studies of the amount, quality and occurrence of the available sources, then the design of the plant in general. Succeeding chapters discuss the winning and purification of water, pumping and conveying, and the operation of waterworks. Attention is directed toward general principles, rather than to the details of specific installations.

Electric Arc Welding. By E. Wanamaker and H. R. Pennington. Simmons-Boardman Publishing Co., New York, 1921. Cloth, 6×9 in., 254 pp., illus., $4.

This manual is based largely on a series of articles published in the *Railway Electrical Engineer*. It contains a large amount of practical information on many phases of the subject; descriptions of systems and their installation, phenomena of metallic and carbon welding arcs, training of welders, sequence of metal deposition for various types of joints and building-up operations, electrodes, thermal disturbances due to welding, properties of welds, efficiency of equipments and costs. The book is confined to autogenous arc welding.

Electric Ship Propulsion. By S. M. Robinson. Simmons-Boardman Publishing Co., New York, 1922. Cloth, 6×9 in., 274 pp., illus., diagrams, $6.

This volume treats of the special questions relating to steam turbines, electric generators, induction motors and other machines, which arise in connection with the propulsion of ships by electricity, and compares this method with others. The various systems are explained and compared. The installations on several ships of the Navy and on the *Wulsty Castle*, which illustrate the application of various systems, are described in detail.

Elements of the Differential and Integral Calculus. By William S. Hall. Second edition, revised. D. Van Nostrand Co., New York, 1922. Cloth, 6×9 in., 250 pp., $2.75.

This textbook is an endeavor to present the calculus and some of its important applications simply and concisely, yet fully enough to make possible the study of subjects that call for knowledge of it. In this new edition chapters 1, 4 and 5 have been rewritten, other revisions have been made and many new problems added.

L'Ether Actuel et ses Precurseurs. By E. M. Lémeray. Gauthier-Villars et Cie, Paris, 1922. (Actualités scientifiques.) Paper, 5×7 in., 141 pp., 6 fr.

The author of this book, an early student of the investigations of Lorentz and Einstein, is a master of the theories of relativity and has written several summaries of them. In the present work he traces the development of the idea of the ether, which these theories tend to modify anew. The book is the result of an extensive examination of the history of science. Beginning with the ideas of the Chaldeans and Egyptians concerning a universal spirit, the modifications due to the Greeks and Romans, the ether of Huyghens, phlogiston, caloric, the ether of Fresnel and that of later students are described.

Factory Administration in Practice. By W. J. Hiscox. Sir Isaac Pitman & Sons, Ltd., New York, 1921. Cloth, 6×9 in., 214 pp., $2.50.

Most of the books on factory administration seem to have been written by accountants for accountants, our author thinks, and as a consequence have disregarded factory conditions to some extent. The present work is written from the factory viewpoint, and is intended for the works manager, the foreman and all members of the factory administrative staff. The views and schemes set forth are the results of sixteen years' practical experience with engineering firms in Great Britain. Special prominence is given to the progress system.

Giesserei-Handbuch. Herausgegeben vom Verein Deutscher Eisengiessereien Giessereiverband in Düsseldorf. R. Oldenbourg, München, 1922. Cloth, 7×10 in., 264 pp., tables, 300 M.

This handbook has been prepared by the German Iron Founders' Association as a convenient compendium of data used by foundry men. It includes the standards adopted by many European railroads, by associations and societies, methods for the analysis of cast iron, coal, coke, slags and flue gases, physical data for iron and other materials, the German standards for cast-iron pipe, tariff and statistical data concerning the trade, trade associations, and directors of German foundries and foundry-supply dealers.

Grundlagen der Flugtechnik. By H. G. Bader. B. G. Teubner, Leipzig, 1920. Paper, 6×9 in., 194 pp., $2.90.

A work for designers of airplanes, dealing with the calculations required and the proper methods and formulas. Covers all the calculations that are needed in practical design and illustrates their uses by application to the calculation of a concrete example. Contains a brief bibliography.

Heating and Ventilation. By John R. Allen and J. H. Walker. Second edition. McGraw-Hill Book Co., Inc., New York, 1922. Cloth, 6×9 in., 332 pp., illus., diagrams, tables, $3.50.

A textbook for use in engineering and architectural schools, intended also for use as a handbook by engineers and architects. A second edition has become desirable because of the advances in the art made recently, such as the establishment of standards for ventilation and the results obtained in the research laboratory of the American Society of Heating and Ventilating Engineers. The text has been thoroughly revised and enlarged to include recent developments.

Hydraulics of Pipe Lines. By W. F. Durand. D. Van Nostrand Co., New York, 1921. (Glasgow textbooks.) Cloth, 6×9 in., 271 pp., diagrams, $4.50.

Intended to give a discussion, in engineering form, of the more important hydraulic problems which arise in connection with pipe lines and pipe-line flow. No attempt is made to treat the subject structurally or descriptively. The successive chapters discuss general hydraulic principles, surge, water ram or shock, stresses in pipe lines, materials, construction, design, and oil pipe lines.

Jigs and Fixtures. By Albert A. Dowd and Frank W. Curtis. First edition. McGraw-Hill Book Co., Inc., New York, 1922. (Tool engineering.) Cloth, 6×9 in., 293 pp., diagrams, $2.50.

This book, the first of three upon the principles underlying the design of production tools, deals with the design of jigs and fixtures for drilling, indexing, milling, profiling, broaching, riveting, etc. A chapter is devoted to vises and vise fixtures. The work deals with principles, although many interesting fixtures are shown to

illustrate their use. The important points connected with the design and the relative desirability of various designs are discussed.

Modern Gasworks Practice. By Alwyne Meade. Second edition. Benn Brothers, Ltd., London, 1921. Cloth, 7×10 in., 815 pp., illus., diagrams, 55s.

The first edition of this book appeared in 1917 and quickly became out of print, through the immediate recognition of its worth as the most complete, authoritative account of modern practice extant. The new edition, while retaining all the merits of the first, has undergone an increase in bulk of 50 per cent through the addition of new matter, and has also been largely rewritten to take account of the upheaval in the technique of gas-works practice in England, caused by the substitution of a calorific standard for the former candlepower standard. Every phase of the works side of gas engineering is covered, from the planning and construction of gas works to the storage of the gas and recovery of the by-products. As a general work of reference, the book is of the greatest value to all engaged in the gas industry.

Operating Engineer's Catechism of Steam Engineering. By Michael H. Gornston. D. Van Nostrand Co., New York, 1922. Fabrikoid, 5 × 8 in., 428 pp., diagrams, $4.

An elementary textbook upon the construction and operation of boilers, steam engines and turbines, heating apparatus and pumping machinery, prepared for operating engineers. Covers the problems that confront the engineer with unusual fullness and is well indexed. Should be of assistance to those preparing for examination and as a pocket reference book.

Petroleum. By Sir Boverton Redwood. Fourth edition. J. B. Lippincott Co., Philadelphia, 1922. Cloth, 6 × 9 in., 3 vol., maps, plates, illus., tables. $21.

Sir Boverton Redwood's classic work is the product of a long professional career as a petroleum technologist, during which he acquired first hand knowledge of oil production, oil fields and oil men in all the important fields of the globe. He was, until his death, in touch with every source of information on petroleum. The material collected, after being critically sifted in the light of his broad experience, has resulted in a book that for twenty-five years has been recognized as an authoritative reference work. The present edition was in preparation when the author died, in 1919, and certain portions had received his final revision. The remaining portions have been revised by his friends, and the work has been seen through the press by A. W. Eastlake and Robert Redwood.

The general plan of previous editions is retained, although the entire work has been reset. Commencing with a historical account of the industry, the distribution, physical and chemical properties, and origin of petroleum are discussed in volume one. Volume two is devoted to production, refining, transportation, storage and distribution, and to the shale oil industry. Volume three treats of testing, uses, and laws; it also contains statistics, import duties and an extensive bibliography. This contains nearly nine thousand references; unfortunately, few, if any, are later than 1911.

Principles and Design of Foundation Air Brake Rigging. Air Brake Association, New York, 1921. Boards, 6×9 in., 121 pp., diagrams, $1.

In the interest of higher air-brake education, the Air Brake Association has secured from the Westinghouse Air Brake Company the right to publish this study of some of the finer points that contribute to the efficiency of air brakes. The book is the joint product of experienced engineers and should be useful to all users and designers of brakes.

Probenahme und Analyse Von Eisen und Stahl. By O. Bauer and E. Deiss. Zweite auflage. Julius Springer, Berlin, 1922. Cloth, 7×10 in., 304 pp., illus., 472 M.

This work presents methods for sampling and analyzing iron and steel adopted by the authors for their work at the National Testing Laboratory in Berlin. The first section, by Prof. Bauer, discusses sampling, emphasizes the importance of proper sampling and gives much information upon proper methods of taking, polishing and etching samples for microscopic examination. The metallographic characteristics of the constituents of iron and steel are described and directions given for securing representative samples of iron and steel for examination. The second section, by Prof. Deiss, gives reliable methods for the accurate chemical determination of the various constituents of iron and steel. This edition has been carefully revised and enlarged.

Questions and Answers Relating to Diesel, Semi-Diesel and Other Internal-Combustion Engines; Air Compressors, etc. By John Lamb. J. B. Lippincott Co., Philadelphia, 1922. Cloth, 4×5 in., 209 pp., $2.50

A small pocket book of practical information for steam engineers and others preparing for license examinations.

Real Mathematics. By Ernest G. Beck. Henry Frowde and Hodder & Stoughton, London, 1922. (Oxford technical publications.) Cloth, 5×8 in., 306 pp., diagrams, 15s.

This book is intended to assist in the acquisition of a real, serviceable, sound mathematical equipment, by augmenting standard textbooks and orthodox methods of study. The author hopes it will contribute toward the adoption of a change of attitude toward mathematics by those who require it as a part of their working equipment, by showing it as an actual, tangible reality, instead of a collection of rigid and unrelated rules and formulas. The method given assists the student to visualize the various operations and processes used in mathematical calculation.

Textbook of Fire Assaying. By Edward E. Bugbee. John Wiley & Sons, Inc., New York, 1922. Cloth, 6 × 9 in., 254 pp., illus.

Based upon the course at the Massachusetts Institute of Technology and intended as a college textbook; but will also be useful, the author hopes, to more mature students. An endeavor has been made to give the scientific reasons underlying the phenomena that occur and the rationale of the processes and manipulations, and to avoid the character of a mere receipt book.

Theory of the Induction Coil. By E. Taylor-Jones. Sir Isaac Pitman & Sons, Ltd., London and New York, 1921. Cloth, 5×8 in., 217 pp., illus., $3.50.

Until recently there has been much divergence of view as to the manner in which the high potential is generated at the secondary terminals of an induction coil when the primary current is interrupted, and it cannot be said even now that opinion on the subject is quite undivided. In this book an account is given of a theory of the action of induction coils first put forward by the author in 1909. The theory was originally intended to apply only to the case of an air-core induction coil having a condenser connected with its secondary terminals. Subsequent investigations have shown that it is also applicable to an ordinary induction coil.

Valuation of American Timberlands. By K. W. Woodward. John Wiley & Sons, Inc., New York, 1921. Cloth, 6×9 in., 246 pp., maps, $3.

Gives the principal facts regarding the timber resources of the continental United States and its outlying territories, excepting Hawaii and the Canal Zone, in a form suited to the needs of investors, timber cruisers and students of forestry. Contains descriptions of the forest types of the country, and comparisons of their values.

Vervollkommnung der Kraftfahrzeugmotoren Durch Leichtmetallkolben. By Gabriel Becker. R. Oldenbourg, München, 1922. Paper, 7×11 in., 97 pp., illus., 75 M.

The first section of this work discusses the possibilities for improving automobile construction by reducing wind resistance and weight, increasing the size and efficiency of the engines, or by perfecting the engines thermodynamically and structurally. The second and longer section gives the results of an interesting series of tests upon light metal pistons, made in 1921 at the automobile testing laboratory of the Berlin Technical High School, under the direction of the author, with the assistance of the German Engine Manufacturers' Association. Extensive tests of 16 different aluminum- and magnesium-alloy pistons are presented and compared with tests of cast-iron and pure copper pistons.

THE ENGINEERING INDEX

(Registered United States, Great Britain and Canada.)

THE ENGINEERING INDEX presents each month, in conveniently classified form, items descriptive of the articles appearing in the current issues of the world's engineering and scientific press of particular interest to mechanical engineers. At the end of the year the monthly installments are combined along with items dealing with civil, electrical, mining and other branches of engineering, and published in book form, this annual volume having regularly appeared since 1906. In the preparation of the Index by the engineering staff of The American Society of Mechanical Engineers some 1200 technical publications received by the Engineering Societies Library (New York) are regularly reviewed, thus bringing the great resources of that library to the entire engineering profession.

Photoprint copies (white printing on a black background) of any of the articles listed in the Index may be obtained at a price of 25 cents a page. When ordering photoprints identify the article by quoting from the Index item: (1) Title of article; (2) Name of periodical in which it appeared; (3) Volume, number, and date of publication of periodical; (4) Page numbers. A remittance of 25 cents a page should accompany the order. Orders should be sent to the Engineering Societies Library, 29 West 39th Street, New York.

ABRASIVES

Properties and Uses. Grinding Wheels (Les Meules Artificielles), E. Assié. Arts et Métiers, vol. 74, no. 12, Sept. 1921, pp. 265–270, 7 figs. Discusses abrasives, carborundum, corundum, melting points, resistance to acid, use as refractories, etc.

ACCELEROMETERS

Auclair and Boyer-Guillon. Auclair and Boyer-Guillon Accelerometers (Les accéléromètres Auclair et Boyer-Guillon), A. Boyer-Guillon. Bul. de la Société d'Encouragement pour l'Industrie Nationale, vol. 133, no. 9, Nov. 1921, pp. 1167–1191, 19 figs. Describes weight, spring and triple-recording accelerometers, and their application in determining acceleration and periodical movements.

ACCIDENTS

Placing Responsibility. Placing Responsibility for Accidents, H. L. Keely. Management Eng., vol. 2, no. 3, Mar. 1922, pp. 149–152, 3 figs. Through classifying according to kind and cause and by estimating cost of remedies.

ACCOUNTING

Pig-Iron Production. Accounting for Pig-Iron Production, Nathaniel B. Bergman. Jl. of Accountancy, vol. 33, no. 2, Feb. 1922, pp. 90–99. Discusses blast-furnace operations and how to deal with them in accountancy.

AERODYNAMICS

Resistance of Bodies. Influence of Model Surface and Air Flow Texture on Resistance of Aerodynamic Bodies, A. F. Zahm. Nat. Advisory Committee for Aeronautics. Report no. 139, 1922, 6 pp. Deals with resistance of smooth models in a smooth stream; resistance as a function of surface texture and of flow texture. More general resistance formulas.

Standardization. Standardization in Aerodynamics, W. Margoulis. Aerial Age, vol. 14, no. 26, Mar. 6, 1922, pp. 614–615. Agrees with article of same title by W. Knight, published in Aerial Age, June 20, 1921, as to standardization on basis of experiments of American, British, French and German quasi-official laboratories.

AERONAUTICS

Hydrodynamics, Application of. Applications of Modern Hydrodynamics to Aeronautics, L. Prandtl. Nat. Advisory Committee for Aeronautics, Report no 116, 1921, 61 pp., 62 figs. Discusses the theoretical underlying principles, theory of aerofoils, and application of aerofoil theory to screw propellers.

AIR COMPRESSORS

Explosions. Explosions in Air Compressors, A. D. Risteen. Sugar, vol. 24, no. 2, Feb. 1922, pp 99–100. Deals with presence of lubricating oil and carbon deposits, and suggests that all accumulation of deposits be prevented. From address before Nat. Safety Council.

AIR CONDITIONINO

Air Drying. The Volume of Air Required in Air Drying, C. T. Mitchell. Chem. & Met. Eng., vol. 25, no 21, Dec 14, 1921, pp. 1088–1090, 3 figs. Factors affecting atmospheric evaporation; cooling of air during evaporation; distinction between wet bulb temperature and dew point; calculation of volume of air required; etc. Charts for 100, 85, and 70 per cent ultimate humidity.

AIRCRAFT

Military, Limitation of. Report of the Sub-Committee on the Limitation of Aircraft. Aerial Age Weekly, vol. 14, no. 23, Feb. 13, 1922, pp. 543–545. Discusses commercial, civil, and military aircraft; impossibility of limitations; gives general summary of conclusions.

AIRCRAFT CONSTRUCTION MATERIALS

Wire Cable, Elasticity of. A Study of the Elastic Properties of Small-Size Wire Cable, R. R. Moore. Mech. Eng., vol. 44, no. 2, Feb. 1922, pp. 105–106 and 111. Results of series of tests carried out at McCook Field, Dayton, Ohio, in which it is shown that modulus of elasticity of small-sized wire aircraft cable varies from 15,000,000 to 28,000,000, depending upon size and type of cable. It was also found that modulus of elasticity may be raised by loading cable below elastic limit and that resting the cable does not seem to have any definite effect on modulus.

AIRPLANE ENGINES

Air-Cooled. Air-Cooled Engine Development, Charles L. Lawrence. Soc. Automotive Engrs. Jl., vol. 10, no. 2, Feb. 1922, pp. 135–141 and 144, 13 figs. Describes British experiments to improve performance of air-cooled engines for aircraft, which lead eventually to development of aluminum cylinders with steel liners and aluminum cylinder heads with steel cylinder screwed into head. Advantages of these and disadvantages of other types.

Gasoline Tests. Tests of Aeroplane Motor with Different Gasolines, O. J. May and Howard Cooper. Sci. Lubrication, July 1921, pp. 9–13, 4 figs. Describes tests made to show effect of using different grades of gasoline in aeronautical engine operation.

AIRPLANE PROPELLERS

Blade Interference. The Fan Propeller and Blade Interference, M. A. S. Riach. Aeronautical Jl., vol. 26, no. 134, Feb. 1922, pp. 63–80, 7 figs. Considers the special case of a propeller working without axial advance in a fluid, i.e., what has been called the "static" case.

Thrust and Torque Characteristics. Tests on Air Propellers in Yaw, W. F. Durand and E. P. Lesley. Nat. Advisory Committee for Aeronautics Report, no. 113, 1921, 37 pp., 26 figs. Results of tests to determine thrust (pull) and torque characteristics of air propellers in movement relative to air in a line oblique to line of shaft, and specifically when such angle of obliquity is large, as in case of helicopter flight with propeller serving for both sustentation and traction.

AIRPLANES

Fighting. Development of the Fighting Aeroplane, F. M. Green. Aeronautical Jl., vol. 26, no. 131, Feb. 1922, pp. 46–55 and (discussion) 56–62, 7 figs. Developments during war; single- and two-seater planes; particulars as to armament, ability to withstand damage, performance and maneuverability, size, and view.

Flying Boats. See FLYING BOATS.

Gliders. See FLIGHT, Soaring.

Helicopters. See HELICOPTERS.

Model Construction. Construction and Testing of Model Airplanes, Walter S. Diehl Aviation, vol. 12, no. 9, Feb. 27, 1922, pp. 262–263, 3 figs. Shows that construction of airplane model can be simplified, in order to obtain most reliable test data. N.A.C.A. Technical Note No. 82.

Paris Show. Seventh International Exposition of Aerial Locomotion (VII Exposition internationale de locomotion aérienne) André Lesage. Génie Civil, vol. 79, nos. 22, 23 and 24, Nov. 26, Dec. 3 and 10, 1921, pp. 464–468, 477–485 and 510–515, 41 figs. Discusses exhibit of French official services, materials, testing laboratories, French meteorological and aerial navigation service. Describes different types of airplanes and airplane engines exhibited.

Passenger. The Problem of the Passenger Aeroplane W. D. Beatty. Aeroplane, vol. 22, no. 2, Jan. 11, 1922, pp. 27–28, 1 fig. Deals with comfort of passengers on commercial aircraft. Discusses desirable attributes not yet incorporated in modern machines; military development of airplane; beginning of commercial development; design of detail; noise; ventilation; heating; etc. Paper read before Roy. Aeronautical Soc.

AIRSHIPS

R 38 Disaster. The Loss of the "R 38." Engineering vol. 113, no. 2931, Mar. 3, 1922, pp. 265–266. Editorial discussion of report of Accidents Investigation Sub-Committee of Aeronautical Research Committee. Fundamental error of judgment made in design appears to have been that calculations of staff failed to take into account the aerodynamic forces to which ship would be subjected in flight, and considered only forces and moments due to distribution of weight and buoyancy, including gas pressures.

ALLOY STEELS

Chrome-Molybdenum. Chrome-Molybdenum-Steel Applications From the Consumer's Viewpoint, C. N. Dawe. Forging & Heat Treating, vol. 8, no. 2, Feb. 1922, pp. 109–113. Results of physical tests, comparing medium-carbon, chrome-molybdenum, chrome-vanadium, chrome-nickel and chrome steels, expressed by means of a merit index. Paper read before Soc. Automotive Engrs.

High Elastic Limit. Some Alloy Steels of High Elastic Limit, Their Heat Treatment and Microstructure, Charles M. Johnston. Am. Soc. for Steel Treating Trans., vol. 2, no. 6, Mar. 1922, pp. 500–506, 13 figs. Describes non-high-speed series which are said to be most promising by reason of tensile values given in tables, and by reason by uniform, tough and dense microstructure of heat-treated condition.

Structural, Tensile Properties of. Tensile Properties of Some Structural Alloy Steels at High Temperatures, H. J. French. U. S. Bur. of Standards Technologic Papers, no. 205, Dec. 21, 1921, pp. 77–92, 8 figs. Results of determination of tensile strength, proportional limit, elongation, reduction of area, and strength at fracture throughout range 20 to 550 deg. cent. for four steels containing about 0.38 per cent carbon. Brief reference is made to type of fractures obtained in testing steels at various temperatures, and particular attention is paid to comparison of tensile properties of these alloys at 550 deg. cent.

ALLOYS

Aluminum. See ALUMINUM ALLOYS.

Bearing-Metal. See BEARING METALS.

Chromium. See CHROMIUM ALLOYS.

Copper. See COPPER ALLOYS.

Lead-Thallium. The Constitution of Lead-Thallium Alloys (Réflexions sur la constitution des alliages Plomb-Thallium), Léon Guillet. Révue de Métallurgie, vol. 18, no. 12, Dec. 1921, pp. 758–760,

4 figs. Describes tests with alloys of various percentages. Gives liquidus curve and micrographs.

Zinc. See ZINC ALLOYS.

ALUMINUM ALLOYS

Calite. Calite—A New Heat Resisting Alloy, G. R. Brophy. Am. Soc. for Steel Treating Trans., vol. 2, no. 5, Feb. 1922, pp. 384–388, 1 fig. Describes properties of new ternary alloy of aluminum, nickel, and iron. See also Iron Trade Rev., vol. 70, no. 10, Mar. 9, 1922, pp. 679–680, 1 fig.

AMMONIA

Vapor Tables. New Ammonia Vapor Tables (Neue Dampftabellen für Ammoniak), E. Altenkirch. Zeit. für die gesamte Kälte-Industrie, vol. 28, no. 12, Dec. 1921, pp. 173–177, 1 fig. Author presents and extends American table prepared by Bur. of Standards, values being changed from Fahrenheit into Celsius and from English into metric units.

AMMONIA COMPRESSORS

Losses in. Analysis of Losses in Ammonia Compressors, S. F. Smith. Ice & Refrigeration, vol. 62, no. 2, Feb. 1922, pp. 154–155. Discusses losses as they occur and conditions which control same.

APPRENTICES, TRAINING OF

Plant vs. Continuation Schools. The Training of Workers in Manufacture, J. V. L. Morris. Am. Mach., vol. 56, no. 7, Feb. 16, 1922, pp. 249–251. General conditions of apprenticeship; problems arising from school, plant school vs. part-time and continuation schools.

AUTOMOBILE ENGINES

Acoustic Volumeters for. The Charron-Godet Acoustic Volumeter (Le volumètre acoustique Charron-Godet), R. Villers. Nature, no. 2493, Jan. 14, 1922, pp. 26–28, 3 figs. Describes apparatus made by Soc. des Accessoires Routiers, used among other things, for detecting unequal combustion chambers in multi-cylinder engines.

Carburetors. See CARBURETORS.

New York Show. Powerplant Trends as Seen at the Show, Herbert Chase. Automotive Industries, vol. 46, no. 2, Jan. 12, 1922, pp. 62–65, 3 figs. Discusses cooling systems, aids to starting, lubrication and piston design, valves, gearing and crankshafts, etc.

Weidely Six-Cylinder. Weidely Producing a New Engine, J. Edward Schipper. Automotive Industries, vol. 46, no. 10, Mar. 9, 1922, pp. 551–553, 5 figs. Is six-cylinder overhead-valve type, intended for light and medium-weight cars; force-feed lubrication used throughout, crankcase and cylinders cast in block; develops 63 hp. at 3000 r.p.m.

AUTOMOBILES

Body-Seating Dimensions. Body Seating-Dimensions, George E. Goddard. Soc. Automotive Engrs. Jl., vol. 10, no. 2, Feb. 1922, pp. 117–120, 1 fig. Considers features conducive of comfort. Factors influencing seat dimensions, and recommendations regarding different desirable dimensions.

Brakes. Automobile Brakes, Sydney V. James. Armour Engr., vol. 13, no. 1, Nov. 1921, pp. 1–21, 9 figs. Discusses mechanics of motion as applied to brakes and braking, actual brake mechanisms and typical braking systems, including both external contracting and internal expanding types, and brake lining materials.

German Maf. The German Maf Automobile (Markranstädter Automobilfabrik, vorm. Hugo Ruppe G.m.b.H., Markranstädt bei Leipzig). Wirtschaftsmotor, no. 9, Sept. 10, 1921, p. 15, 3 figs. on pp. 14 and 16. Describes automobile chassis and engine constructed by the Markranstadt Automobile Factory, near Leipzig, said to be only German car with air-cooled engines. Constructed as sport two-, three- and four-seated car, sport phaeton, landaulet and delivery wagon.

Manufacturing Plants. A Modern Automobile Plant, Paul L. Battey. Management Eng., vol. 2, no. 3, Mar. 1922, pp. 167–172, 8 figs. Arrangement of departments, routing of product, and means of transportation. (Abstract.) Paper presented to Metropolitan Section of Am.Soc.Mech.Engrs.

The New Plant of the Fisher Body Ohio Co. (Cleveland). Power Plant Eng., vol. 26, no. 4, Feb. 15, 1922, pp. 201–209, 13 figs. Largest single-unit automobile-body manufacturing plant in world. Exemplifies modern construction in its highest degree.

New York Show. Trends in Chassis Design at the New York Show, P. M. Heldt. Automotive Industries, vol. 46, no. 2, Jan. 12, 1922, pp. 58–62, 8 figs. Discusses various improvements, including changes in clutch, transmission locks, gear shifting, and steering wheel.

Pressed-Steel Parts. Making Pressed Steel Automobile Parts. Iron Trade Rev., vol. 70, no. 9, Mar. 2, 1922, pp. 601–604, 8 figs. Details of plant of the Sharon Pressed Steel Co., Sharon Pa.

Repair-Shop Practice. Automobile Repair Shop Practice. Machy. (N. Y.), vol. 28, nos. 5, 6 and 7, Jan., Feb. and Mar. 1922, pp. 359–362, 468–470, 7 figs. and 567–568, 2 figs. Describes methods and equipment commonly employed. Feb.: Machining pistons. Mar.: Regrinding crankshaft bearings.

Shock Insulators, Rubber. Rubber Shock Insulators. Rubber Age, vol. 2, no. 12, Feb. 1922, p. 503, 4 figs. Describes tests carried out in London and New York to demonstrate efficiency of rubber insulators in damping vibration and producing easy riding.

Spring-Bolt Lubrication. The Lubrication of Joint Pins, Especially Automobile Spring Bolts (Die Schmierung von Gelenkbolzen insbesondere der Automobil-Federbolzen), R. Bussien. Motorwagen, vol. 25, no. 3, Jan. 31, 1922, pp. 46–47, 9 figs. Describes new type of spring bolt, with use of which problem of lubrication is satisfactorily solved. Oil is fed directly to place of lubrication and dead space between place of lubrication and grease chamber is reduced to a minimum.

Statistics. Automobile Statistics. Automotive Industries, vol. 46, no. 7, Feb. 16, 1922, pp. 309–429. Special number giving statistical data concerning registrations, production, specifications, exports, and general automotive statistics.

Transmission Case. The Wills Sainte Claire Transmission Case, Fred H. Colvin. Am. Mach., vol. 46, no. 9, Mar. 2, 1922, pp. 323–325, 8 figs. Is of "bell" type and bolts direct to end of crankcase. After cleaning and inspecting, it is water-tested for blowholes or leaks and then spotted in three places for locating in future operations.

AVIATION

Commercial. Air Lines and Some of Their Problems, R. B. C. Noorduyn. Mech. Eng., vol. 44, no. 2, Feb. 1922, pp. 107–109 and 111. Detailed account of progress of commercial aviation in Europe, tracing development from time of post-war experimental work with military machines and fields, to present successful operation with proper machines and schedules and with Government subsidies.

Dead Reckoning, Checking. Methods of Air Navigation, Herbert V. Thaden. Aviation, vol. 12, no. 9, Feb. 27, 1922, pp. 252–255, 6 figs. Formula and instruments for checking dead reckoning.

Requirements and Difficulties. The Requirements and Difficulties of Air Transport, Frank Searle. Aeronautical Jl., vol. 26, no. 133, Jan. 1922, pp. 3–10 and (discussion) 10–20. Discusses requirements of engine, as a source of power, and the plane, both as a device for rising into air, staying in air, and descending from air to land in a satisfactory way; accommodation of travelers; and rapidity and certainty of service at a proper price.

Research. The Progress of Research, R. K. Bagnall-Wild. Engineer, vol. 133, no. 3450, Feb. 10, 1922, pp. 161–162. Research work for air service in Great Britain comprises specific researches at establishments under control of Air Ministry, and in addition an important series of studies carried out in universities by arrangement with the Ministry. Notes on aero-engine research, navigation, and machines. See also Engineering, vol. 113, no. 2929, Feb. 17, 1922, pp. 214–216. Paper read at Air Conference, London.

B

BEAMS

Continuous. Calculation of Continuous Beams (Beitrag zur Berechnung des kontinuierlichen Trägers), Josef Vinzens. Bauingenieur, vol. 2, no. 24, Dec. 31, 1921, pp. 695–698, 6 figs. Calculating method is developed showing how, with aid of known or determined moments of support for uniform load of bays of continuous beam, the influence of another bay-symmetrical load can be directly ascertained without special intermediate calculation.

BEARING METALS

Arsenical. Arsenical Bearing Metals, Harold J. Roast and Charles F. Pascoe. Min. & Metallurgy, no. 182, Feb. 1922, pp. 63–64. Investigation for purpose of comparing arsenical antimony-lead alloy with some of the regular bearing-metal alloys. (Abstract.) See also Am. Inst. Min. & Met. Engrs. Trans., no. 1136-N, Feb. 1922, 10 pp. 7 figs. (complete paper).

BEARINGS, THRUST

Improved Types. Progress in the Construction of Thrust and Journal Bearings (Neuerungen im Bau von Druck- und Traglagern), H. Schneider. Oel- u. Gasmaschine, vol. 18, no. 12, Dec. 1921, pp. 196–199, 9 figs. Describes new types and improvements, including the single-pulley thrust bearings developed by Fried. Krupp Germania Shipyards, which have given such good experimental results that they are to be installed in submarines of the German navy.

BELTING

Leather, Specifications. Outline of U. S. Specifications for Leather Belting, R. C. Bowker. Belting, vol. 20, no. 2, Feb. 1922, pp. 30–31. To be used by all government departments, but designed also for all consumers; now before Bureau of the Budget for consideration. (Abstract.) Address before Nat. Assn. Leather Belting Manufacturers.

Power Transmission by. Transmission of Power in Plant of Mid-West Glass Co., H. Hilman Smith, Jr. Belting, vol. 20, no. 2, Feb. 1922, pp. 26–28, 4 figs. System characterized by line-shafts supported from floor stands driving direct to all machines, latter equipped with tight and loose pulleys.

Width, Determining. Charts for Determining Belt Widths, Thomas J. Cook. Machy. (N. Y.), vol. 28, no. 7, Mar. 1922, pp. 562–564, 3 figs. Presents charts devised by author which, it is claimed, should enable any one to ascertain at a glance the most efficient size of belt to be used for any condition which may arise.

BLOWERS

Turbo. Turbo-Blowers for Mechanical-Draft Applications. Power, vol. 55, no. 8, Feb. 21, 1922, pp. 307–308, 2 figs. Four blowers are worked in parallel and directly connected to turbine operating at 5000 r.p.m. These machines are applied to both forced- and induced-draft purposes.

BOILER FEEDWATER

Automatic Regulation. Automatic Feed Regulation. Mar. Engr. & Naval Architect, vol. 45, no. 533, Feb. 1922, p. 53, 1 fig. on p. 52. Describes the Mumford automatic feedwater regulator now being fitted on White Star liner "Majestic."

Treatment. Critical Discussion of the Different Methods of Boiler Feedwater Treatment (Kritik der verschiedenen Methoden der Reinigung von Kesselspeisewasser), B. Preu. Dinglers polytechnisches Jl., vol. 337, nos. 1 and 2, Jan. 14 and 29, 1922, pp. 1–4 and 11–13. Discusses criteria for obtaining best possible purification and advantages and disadvantages of different processes.

BOILER OPERATION

Automatic Draft Regulation. Automatic Draft Regulation in Steam Boiler Rooms (La régulation automatique du tirage das les chaufferies de générateurs à vapeur), Jean Delestrade. Technique Moderne, vol. 13, no. 12, Dec. 1921, pp. 510–518, 14 figs. Describes complete operation of a battery of four Babcock boilers, of which one is auxiliary, producing 10,000 kg. steam per hr. at 14.5 kg. pressure.

Present-Day. Present-Day Boiler-Room Operation, I. E. Moultrop and R. E. Dillon. Power, vol. 55, no. 10, Mar. 7, 1922, pp. 384–386, 6 figs. Discusses economical loading of turbines and boilers. Paper read before Metropolitan Sections of Am.Soc.Mech. Engrs. and Am.Inst.Elec.Engrs.

BOILER PLANTS

Design. Common Faults in Boiler-Plant Design, George C. Cook. Power, vol. 55, no. 7, Feb. 14, 1922, p. 251. One of most frequent faults is said to be failure to provide sufficient space. Valves should be accessible. Influence of fuel on design.

Supervision. Supervision of Steam Boiler Plants, H. Germer. Eng. Progress, vol. no. 2, pp. 42–43, 4 figs. Deals with constant-volume, piston disk, Woltmann, venturi and Venturi steam meters.

BOILER ROOMS

Flue-Dust Blowers and Catchers. Flue-Dust Blowers and Catchers, Particularly for Flue Boilers (Flugaschenbläser und Flugaschenfänger, insbesondere für Flammrohrkessel), H. Pradel. Braunkohle, vol. 20, no. 36, Dec. 10, 1921, pp. 564–569, 11 figs. Describes new types by German firms.

BOILERS

Marine. See MARINE BOILERS.

Oil in. Lubrication and the Steam Boiler, Edward L. Gross. Sci. Lubrication, Oct. 1921, pp. 8–9. Discusses oil in steam boiler, and foaming and priming, and the remedies.

Scale Removal with CO_2. Removing Boiler Scale with CO_2, R. J. Cross and Roy Irvin. Power, vol. 55, no. 11, Mar. 14, 1922, pp. 422–423, 1 fig. Some scales are removable by carbonated water. Work done with ordinary "soda-fountain" cylinders of liquid carbon dioxide. Preliminary tests easy to make.

Setting. Large Combustion Chamber in Rear of Boiler, to Which Heated Air Is Admitted, Increases Efficiency, Alphonse F. Brosky. Coal Age, vol. 21, no. 7, Feb. 16, 1922, pp. 288–289, 1 fig. Air heated in flue passing under combustion chamber, is emitted through passages in bridge wall, causing combustion of unburned hydrocarbons and carbon monoxide.

Triple-Riveted Butt Joint. The Designing of a Triple Riveted Butt Joint, L. T. Rutledge. Can. Machy., vol. 27, no. 6, Feb. 9, 1922, pp. 17–19, 1 fig. Strength of boiler shell; sketching proposed joint; resistance against tearing and crushing.

Up- vs. Down-Draft Smokeless. Up-Draft Versus Down-Draft Smokeless Boilers. Heat. & Vent. Mag., vol. 19, no. 2, Feb. 1922, pp. 29–30, 1 fig. Air over fire needed only part of time; rate at which air is demanded; value of preheating air.

BOILERS, WATER-TUBE

Marine. Emergency Fleet Corporation Water-Tube Boilers for Wood Ships, F. W. Dean. Mech. Eng., vol. 44, no. 2, Feb. 1922, pp. 99–102 and (discussion) p. 104, 6 figs. Results of evaporative tests of four-pass boiler, having heating surface of 2518 sq. ft., furnace volume of 408 cu. ft. and a commercial horsepower of 435 on basis of marine rating of 6 lb. of water to square foot of heating surface per hr.

BONUS SYSTEMS

Heat-Treating Department. A Successful Bonus System Applied to Heat Treating, A. A. Blue. Am. Soc. for Steel Treating Trans., vol. 2, no. 5, Feb. 1922, pp. 430–436, 2 figs. Summarizes general principles and practical details of a successfully tried-out bonus system.

BORING

Spherical Housing. Boring a Spherical Housing on an Automatic Machine, P. J. Tomkins. Machy. (Lond.), vol. 19, no. 488, Feb. 2, 1922, pp. 541–542, 4 figs. Describes the difficulties and how they were overcome.

BRAKES

Bus, Hydraulic. Four-Wheel Hydraulic Brake Tried on California Bus. Elec. Ry. Jl. (Bus Transportation), vol. 50, no. 6, Feb. 11, 1922, p. 123. Brake installed in 18-passenger Pierce-Arrow bus by Pickwick Stage Co., Los Angeles, has proved highly satisfactory so far.

BRONZES

Manganese. The Effect of Solders on Beta Brasses. Eng. Rev., vol. 35, no. 7, Jan. 1922, p. 233. Account of investigations made by J. H. S. Dickenson, commenced in order to account for failure of a manganese bronze, or Beta brass forging of a turbo-alternator.

C

CABLEWAYS

Electric Suspension. Electric Suspension Railways with Self-Acting Grippers, P. Stephan. Eng. Progress, vol. 3, no. 2, Feb. 1922, pp. 34–37, 13 figs. Design and method of working. Describes a Bleichert electric grab suspension railway and a conveying plant for coal and coke.

CAR LIGHTING

Electric. Electric Illumination for Trains, Richard Hanchen. Eng. Progress, vol. 3, no. 1, Jan. 1922, pp. 1–3, 6 figs. Notes on continuous electric train lighting for individual cars; drive of dynamo; voltage control; charging and life of battery, etc.

Principles of Car Lighting by Electricity—XVII, Charles W. T. Stuart. Ry. Elec. Engr., vol. 13, no. 1, Jan. 1922, pp. 9–17, 15 figs. Describes the Gould simplex system of car lighting, consisting of a generator driven by a belt from car axle, a generator regulator panel, a lamp regulator panel mounted in a cabinet inside or under car body, and a storage battery suspended in a box under car body.

CARBON DIOXIDE

Pressure-Total-Heat Diagram. Pressure-Total-Heat Diagram For Carbon Dioxide, H. J. MacIntire. A.S.R.E. Jl., vol. 8, no. 3, Nov. 1921, pp. 211–215, 1 fig. Describes diagram, said to be accurate, clear and workable. Drawn with rectangular coördinates, using pressures for ordinates and total heat in B.t.u. above 32 deg. fahr. as abscissae.

CARBURETORS

Triple-Emulsion Automatic. A New Triple-Emulsion Automatic Carburetor (Un nouveau carburateur a triple emulsion et economiseur automatique), Ach. Delamarre. Outillage, vol. 242, no. 2, Jan. 14, 1922, pp. 48–49, 4 figs. Describes the Paget patent carburetor "Eclipse."

CARS

Hose Connectors. Recent Changes in American Hose Connectors. Ry. Age, vol. 72, no. 6, Feb. 11, 1922, pp. 375–377, 4 figs. Describes connector manufactured by Am. Automatic Connector Co., Cleveland, Ohio, and tests made.

The Development of the Robinson Connector. Ry. Mech. Engr., vol. 96, no. 2, Feb. 1922, pp. 77–81, 9 figs. Latest type incorporates improvements suggested by extensive service of earlier design.

CARS, PASSENGER

Articulated Dining. Articulated Units Feature Recent English Car Design. Ry. Rev., vol. 70, no. 4, Jan. 28, 1922, pp. 109–113, 6 figs. Describes new dining-car train, showing advantages of articulated design and use of electricity for cooking.

Sleeping and Compartment. New Sleeping and Compartment Cars for the C. P. R. Ry. Rev., vol. 70, no. 3, Jan. 21, 1922, pp. 77–81, 8 figs. Designed for service on transcontinental trains with special regard for comfort of women travelers.

CASE-HARDENING

Cyanamide for. Cyanamide in Liquid Case Hardening, P. W. and E. B. Shimer. Am. Soc. for Steel Treating Trans., vol. 2, no. 5, Feb. 1922, pp. 403–408. Account of experiments made with and description of the Shimer case-hardening process, making use of special lump calcium cyanamide and easily fusible mixture of salts.

Steel, Effect of Quality on. Effect of Quality of Steel on Case-carburizing Results, H. W. McQuaid and E. W. Ehn. Min. & Metallurgy, no. 182, Feb. 1922, pp. 60–61. Writer seeks to prove that presence of excess dissolved oxides in steel, as made in melting furnace, affects permanently results obtained in carburizing and hardening and that it is possible that presence of dissolved oxide can result in total unfitness of low-carbon steel for case hardening purposes. (Abstract.) See also Am. Inst. Min. & Met. Engrs. Trans., no. 1135–S, Feb. 1922, 22 pp. 46 figs. (complete paper.)

CAST IRON

Desulphurization of Liquid. The Desulphurization of Liquid Cast Iron (Entschwefelung von flussigem Gusseisen), Ludwig Scharlibbe. Giesserei-Zeitung, vol. 19, no. 3, Jan. 17, 1922, pp. 43–46 and (discussion) pp. 46–51, 6 figs. Describes new process for removal of sulphur from molten liquid, resulting in a desulphurization up to 60 per cent of original sulphur content.

Gray, Metallography of. Apply Metallography to Gray Iron, J. W. Bolton. Foundry, vol. 50, nos. 2 and 3, Jan. 15 and Feb. 1, 1922, pp. 52–55 and 109–112, 23 figs. Jan. 15: Describes methods of making photomicrographs, including sampling, polishing, etching and photographing. Shows means for identifying the different structures. Feb. 1: Metallurgical control of cupola.

Piping. The Piping of Cast Iron (Ueber das Lunkern von Gusseisen). Giesserei-Zeitung, vol. 19, no. 5, Jan. 31, 1922, pp. 75–81. Discussion of nature and causes of piping. Abstracts of three papers presented before South German Group of Assn. German Foundrymen, followed by discussion.

Welding Without Studding. Welding Cast Iron Without Studding, F. L. Paertch. Welding Engr., vol. 7, no. 2, Feb. 1922, pp. 28–29 (includes discussion). A process which is feasible in some cases but not recommended for strength members and live loads. Paper read before Am. Welding Soc.

CASTING

Centrifugal. Centrifugal Casting, L. Cammen. Chem. & Met. Eng., vol. 26, no. 8, Feb. 22, 1922, pp. 354–358, 4 figs. Describes process of centrifugal casting of hollow metal objects. Mechanics of centrifugal casting.

Steel Mill Rolls. Rolls Molded in Sectional Flasks, J. R. Hadsum. Foundry, vol. 50, no. 5, Mar. 1, 1922, pp. 206–207, 2 figs. Alternative method to sweep molding. Mold finished in sections and clamped together.

Tunnel Segments. Tunnel Segment Casting Methods. Foundry, vol. 50, no. 4, Feb. 15, 1922, pp. 137–141, 6 figs. Discusses technical difficulties in producing castings for lining of vehicular tunnel under Hudson River.

CENTRAL STATIONS

Operating Expenses. Operating Expenses of Six Plants. Elec. World, vol. 79, no. 3, Jan. 21, 1922, pp. 131–132. Study of Massachusetts stations emphasizes advantages of electrical equipment from upkeep standpoint. Data indicate changes which are taking place as result of transition to new industrial basis.

CENTRIFUGES

Draining Crystals in. Draining Crystals in a Centrifugal Machine, Thomas James Drakeley and George Frank Martin. Soc. Chem. Industry Jl., vol. 40, no. 24, Dec. 31, 1921, pp. 308T–310T, 1 fig. Results of a series of experiments conducted on a large Watson-Laidlaw centrifuge to extract mother liquor from crystals.

CHARTS

Engineering. Practical Engineering Charts, K. F. Smith. Am. Soc. Naval Engrs. Jl., vol. 34, no. 1, Feb. 1922, pp. 56–72, 4 figs. Describes charts for graphical solution of equations with x and y, or z and w given.

CHUCKS

Magnetic. Direct Current or Alternating Current for Magnetic Chucks (Gleichstrom oder Wechselstrom für Spannfutter), B. Wittkuhns. Elektrotechnik u. Maschinenbau (Anzeiger), vol. 40, no. 5, Jan. 29, 1922, pp. 21–22. Results of tests made on magnetic chuck for alternating current to determine its properties when compared with d.c. chucks. It is shown that only advantage of a.c. chuck is the instant demagnetization attained with its use, but there are a great many insurmountable disadvantages.

CHROMIUM ALLOYS

Expansibility. Expansibility of Chromium and Nickel-Chromium Alloys in a Large Interval of Temperature (Dilatabilité du chrome et des alliages nickel-chrome dans un intervalle étendu de températures), P. Chevenard. Comptes Rendus des Séances de l'Académie des Sciences, vol. 174, no. 2, Jan. 9, 1922, pp. 109–112, 2 figs. Describes experiments carried out by means of dilatometer and gives curves resulting.

COAL HANDLING

Equipment. Car Dumper and Coal Conveyors at Coke Oven Plant. Eng. News-Rec., vol. 88, no. 10, Mar. 9, 1922, pp. 407–409, 4 figs. Rotary cradle serves conveying belts. Traveling bridge has belt for storing coal and grab bucket to reclaim it.

Locomotive Loading Plant. Locomotive Coal and Ash Handling Plant. Eng. Rev., vol. 35, no. 7, Jan. 1922, pp. 226–228, 3 figs. Describes plant of Lond. & North Western Ry. Co., capable of loading locomotive in 30 sec.

Unloading Railway Trucks. The Unloading of Bulk Goods (Zur Frage des Umschlages von Massengütern), Hubert Hermanns. Zeit. des Vereines deutscher Ingenieure, vol. 66, no. 5, Feb. 4, 1922, pp. 112–114, 7 figs. Description of the Heinzelmann elevator discharger for the unloading of railway trucks; comparison with tipping devices from economic standpoint.

COMBUSTION

Control. Gas and Air Mixers for Combustion Control, T. L. Hiles. Forging & Heat Treating, vol. 8, no. 2, Feb. 1922, pp. 124–125. Discusses difficulties in producing a perfect combustible mixture of gas and air at burner outlet of a gas furnace.

CONDENSERS, STEAM

Spray-Nozzle Cooling of Condenser Water. Spray-Nozzle Cooling Theory and Practice, B. H. Coffey and G. S. Dauphinee. A.S.R.E. Jl., vol. 8, no. 3, Nov. 1921, pp. 177–202, 6 figs. Discusses the three varieties of variables affecting spray cooling, viz.: independent natural variables which we cannot control; independent artificial variables which we can control; and the final temperature, produced by the mutual reactions of the others and, consequently, the dependent variable.

Testing Apparatus. Testing Condenser Apparatus, R. N. Ehrhart. Power, vol. 55, no. 7, Feb. 14, 1922, pp. 248–250, 7 figs. How commercial tests are made on ejectors, circulating and condensate pumps.

Tubes. British Standard Specification for Condenser Tubes and Screwed Glands for Condensers for Marine Purposes. British Eng. Standards Assn., no. 145, Oct. 1921, 7 pp., 3 figs. Specifications for quality of material, manufacture, dimensions, weight, hydraulic and mechanical tests, inspection and testing facilities.

Properties of Condenser Tubes. Power, vol. 55, no. 9, Feb. 28, 1922, pp. 343–344. Muntz and Admiralty metals are discussed. Discusses the effects of internal strains, crystalline structure and thickness of tubes.

CONNECTING RODS

Bearing Machine for. Universal Bearing Machine for Connecting Rods. Western Machy. World, vol. 13, no. 2, Feb. 1922, pp. 48–52, 15 figs. Designed for use in pouring and boring of bearings for automotive connecting rods. Manufactured by Automatic Bearing Machine Co., San Jose.

CONVEYORS

Advantages. The Influence of Mechanical Conveyors Upon Financial and Operating Policies, W. L. Churchill. Management Eng., vol. 2, no. 3, Mar. 1922, pp. 133–136, 7 figs. It is pointed out that a completely conveyorized plant automatically secures advantage of cost reduction, speedy delivery to customers, minimum capital investment, and a highly stimulated industrial organization.

Steel-Band. Novel Applications for Thin Steel Bands, Bernard Kruger. Iron Age, vol. 109, no. 10, Mar. 9, 1922, pp. 640–642. Special advantages are said to follow their use for power-transmitting and conveying purposes. Question of tension important. Paper presented before West. Soc. of Engrs.

COOLING LIQUIDS

Recooling Plants. Modern Types of Recoolers (Neuere Bauarten von Ruckkühlanlagen), F. Seufert. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 51, Dec. 17, 1921, pp. 1307–1310, 16 figs. Disadvantages of older types are said to be: excessive delivery head of the hot water, dead air space in lower part of cooling tower, and insufficient atomization of dripping water. These disadvantages are eliminated in modern types. Results of tests.

COOLING TOWERS

Recooling of Water in. The Recooling of Water in Self-Ventilating Tower Coolers (Ueber die Wasserrückkühlung mit selbstventilierendem Turmkühler), Carl Geibel. Zeit. des Vereines deutscher Ingenieure vol. 66, nos. 2 and 4, Jan. 14 and 28, 1922, pp. 31–36 and 88–91, 49 figs. (Abstract.)

COPPER ALLOYS

Copper-Tin-Zinc. Copper—88, Tin—10, Zinc—2, R. R. Clarke. Metal Industry (N. Y.), vol. 20, no. 2, Feb. 1922, pp. 56–57, 1 fig. Analysis of properties, idiosyncrasies and methods of producing this mixture.

Phosphor-Copper. Phosphor-Copper, J. L. Jones. Metal Industry (Lond.), vol. 20, no. 7, Feb. 17, 1922, pp. 145–146. Its uses and methods of obtaining best results.

COST ACCOUNTING

Chemical. Some Phases of Chemical Cost Accounting, C. B. E. Rosén. Chem. Age (N. Y.), vol. 29, no. 12, Dec. 1921, pp. 501–504. Discusses the question of process costs and their management.

Machine-Rate. Machine Rate Costing in Engineering Manufacturing Works, G. W. Beale. Jl. Indus. Administration, vol. 1, no. 8, Dec. 1921, pp. 246–253. Series of arguments leading to the conclusion that it is not commercially profitable to include machine rate costs in the routine-recorded system of cost accounts of an engineering manufacturing works, but that it finds its true place in estimated costs.

CRANES

Electrical Apparatus for. Selection of Electrical Apparatus for Cranes, R. H. McLain. Am. Inst. Elec. Engrs. Jl., vol. 41, no. 3, Mar. 1922, pp. 249–256. Paper is intended to assist crane designers and electrical engineers in mills and factories to select proper size and kind of motor by mathematical calculation from given data, and refers particularly to electric overhead traveling crane. It is shown how to calculate power required of motor for hoisting and how to select particular kind of motor needed.

Locomotive. Getting the Maximum Performance Out of Locomotive Cranes. Ry. Maintenance Engr.; vol. 18, no. 2, Feb. 1922, pp. 49–53, 3 figs. Describes the many purposes for which Lehigh Valley R. R. has found it profitable to use them in maintenance-of-way work.

CRANKPINS

Lubrication. An Analysis of a Point in Crank Lubrication. Automotive Industries, vol. 46, no. 8, Feb. 23, 1922, pp. 462–463, 10 figs. Analytical investigation to determine best location for crankpin oil holes.

CRANKSHAFTS

Balancing Machine. A New Crankshaft Balancing Machine, P. M. Heldt. Automotive Industries, vol. 46, no. 9, Mar. 2, 1922, pp. 518–519, 3 figs. Obviates need for preliminary static balance and permits of quickly determining magnitudes and proper angular positions of correcting moments required to insure accurate dynamic balance.

CUPOLAS

Operation and Control. Operation and Control of Cupolas (Conduite et Contrôle des Cubilots), Maurice Bouffart. Fonderie Moderne, no. 12, Dec. 1921, pp. 372–377, 10 figs. Discusses the various chemical and physical measurements, including temperature measurements in melting zone and in charge. Paper read before Congrès de Fonderie de Liége.

CURVES

Polytropic. The Plotting of Polytropic Curves (Ueber Polytropen-Konstruktionen), Emil Wellner. Dinglers Polytechnisches Jl., vol. 336, nos. 24 and 25, Dec. 3 and 17, 1921, pp. 337–339 and 347–350, 13 figs. Method of plotting curves based on the Ebner construction, which permits the finding in a purely geometrical way of curve points at any given ordinate points. Constructions are given for representation of the mechanical work in linear form and for finding mean indicated pressure.

D

DIE CASTING

Uses and Machines for. Die Casting, A. G. Hopkins. Instn. Mech. Engrs. Proc., no. 1, 1922, pp. 23–33 and (discussion) 36–40, 7 figs. Deals with uses and advantages, permanent molds, lead base, zinc base, tin base, aluminum base and copper base alloys, design of dies, die casting machines.

DIESEL ENGINES

Compressors for. The Use of Compressed Air in Diesel Engined Ships, William Reavell. Engineering, vol. 113, no. 2928, Feb. 10, 1922, pp. 179–183, 26 figs. partly on p. 170. (Abstract.) Paper read before North-East Coast Instn. Engrs. & Shipbuilders.

Efficiency. Efficiency of the Diesel Oil Engine, L. H. Morrison. Power, vol. 55, no. 9, Feb. 28, 1922, pp. 340–341, 3 figs. Diesel engine, unlike all other prime movers, is thermally more efficient at part loads, reason for which is explained.

Marine. Some Problems of Marine Diesel Engine Design, P. Belyavin. North-East Coast Instn. Engrs. & Shipbuilders, advance proof, no. 2211-Q, for meeting Feb. 24, 1922, 29 pp., 23 figs. Discusses important points which have a substantial influence on size, cost and weight of multi-cylinder, two-stroke-cycle Diesel engine.

DROP FORGINGS

Heat Treatment. Heat-treatment of Drop-forgings. Machy. (Lond.), vol. 19, no. 488, Feb. 2, 1922, pp. 554–557, 5 figs. Practice followed and equipment employed, with special reference to furnace design and suitable fuels.

Perfecting. Perfecting a Drop Forging, J. H. G. Williams. Am. Soc. for Steel Treating Trans., vol. 2, no. 5, Feb. 1922, pp. 390–395, 13 figs. Includes photographs showing how metal did not flow in manner originally planned, and discusses methods used for removing conditions promoting formation of defects.

DURALUMIN

Gear Material. Duralumin and Its Use as a Gear Material, Robert W. Daniels. Machy. (N. Y.), vol. 28, no. 7, Mar. 1922, pp. 542–543. Notes on physical properties and general characteristics of duralumin; process of manufacture. It is said to be an ideal material for worm wheels. (Abstract.) Paper read before Am. Gear Mfrs. Assn.

DYNAMOMETERS

Hydraulic Traction. The Polak Hydraulic Traction Dynamometer. Engineering, vol. 113, no. 2931, Mar. 3, 1922, p. 256, 4 figs. Describes instrument designed by M. W. Polak, Holland, for testing agricultural machinery. It does not draw a curve, but measures average drawbar pull during certain periods, mostly of 20 sec.

E

EDUCATION

American, Foreign Criticism of. Foreign Criticism of American Education, W. J. Osburn. U. S. Dept. of Interior, Bur. of Education Bul., no. 8, 1921, 156 pp. Contains extracts of reports made by educators and critics of education from other countries who have visited American schools, usually for purpose of gaining such information and ideas as would be helpful to them in improvement of schools of their countries.

EDUCATION, ENGINEERING

Industries. Professional Engineering Education for the Industries, Francis, C. Pratt. Eng. Education, vol. 12, no. 5, Jan. 1922, pp. 227–233. Discusses American methods of engineering education, based on result of careful study of large number of college graduates at works of Gen. Elec. Co. Writer is against too early specialization of student, resulting in turning out a disproportionate number of men of mediocre ability and narrowly specialized education.

Metallurgical Course. A University Course in Metallurgical Engineering, W. P. Wood. Am. Soc. for Steel Treating Trans., vol. 2, no. 5, Feb. 1922, pp. 423–425. Presents curriculum prepared by author having in mind preparation of students for those industries which are concerned with final shaping and preparing of metal for use.

Mining Curriculum. The Mining Curriculum at Lehigh University, George J. Young. Eng. & Min. Jl., vol. 113, no. 6, Feb. 11, 1922, pp. 239–242, 8 figs. partly on p. 238. Discusses curriculum.

EDUCATION, INDUSTRIAL

Industries and Railroads. A Review of Industrial Education and Training. Mech. Eng., vol. 44, no. 2, Feb. 1922, pp. 87–92. Education and Training in the Industries, R. L. Sackett. Education and Training on Railroads, D. C. Buell. Discussion.

ELECTRIC DRIVE

Machine-Tool Shop. Individual Electric Drive in a Machine Tool Shop (La commande électrique individuelle dans un atelier de machines-outils), R. Michean. Arts et Métiers, vol. 74, no. 10, July 1921, pp. 203–212, 25 figs. Deals with single-pulley drives, cone-pulley drives, and multiple-shaft drives, and their difficulties.

ELECTRIC FURNACES

Electromagnetic Motions in. Electromagnetic Motions in Electric Furnaces, Carl Hering. Am. Electrochem. Soc. advance paper, no. 2, for meeting Apr. 27–29, 1922, pp. 7–14. Describes how new proposed law given in former paper may be applied to production, by the current, of certain desired motions such as those for circulating or stirring liquid conductors in a furnace.

Future Applications. The Electric Furnace Situation. Blast Furnace & Steel Plant, vol. 10, no. 2, Feb. 1922, pp. 137–139. Deals with widening of sphere of electric furnace's operation, including production of cast iron.

Gray-Iron Castings. Electric Furnace Strengthens Iron, D. Wilkinson. Foundry, vol. 50, no. 4, Feb. 15, 1922, pp. 143–145. Reviews work on production of synthetic pig iron, and describes an inexpensive type of electric furnace for gray-iron castings.

Iron Smelting. Electric Iron Smelting. Pacific Mar. Rev., vol. 19, no. 2, Feb. 1922, pp. 126–128, 2 figs. Describes "Elektrometalls" process as carried out at Tröllhattan Falls, Sweden, based on inventions made by Gronwall, Lindblad and Stalhane.

Italian Design. Italian Firm Designs An Electric Furnace. Foundry, vol. 50, no. 5, Mar. 1, 1922, p. 177, 1 fig. Describes electric furnaces placed on market by Fiat Corp., Italian automobile builder, producing 1,000 metric tons of finished steel per month.

ELECTRIC LOCOMOTIVES

Chile. Passenger Locomotives for Chilean State Railways. Elec. Ry. Jl., vol. 59, no. 8, Feb. 25, 1922, pp. 309–314, 18 figs. partly on p. 308. Describes electric locomotives for express and local service on line under electrification between Valparaiso and Santiago. See also Ry. Age, vol. 72, no. 9, Mar. 4, 1922, pp. 527–528, 3 figs.

Driving Gears. New Driving Gear for Electric Locomotives (Neuer Antrieb für elektrische Lokomotiven), H. Hoepner. Verkehrstechnik, vol. 38, no. 35, Dec. 15, 1921, pp. 547–548, 2 figs. Describes new transmission system, tests on a model of which are being conducted by the Campagnie Paris-Lyon-Mediterannée in their Paris workshops; results thus far are very satisfactory.

The Driving Gear of Electric Locomotives (Het mechanische gedeelte van het drijfwerk van electrische locomotieven en motorwagens), H. S. Hallo. Ingenieur, vol. 37, no. 2, Jan. 14, 1922, pp. 24–37, 27 figs. Discusses the Batchelder, Chicago-Milwaukee-St. Paul, Westinghouse flexible, General Electric spring gears, and other types.

ELECTRIC WELDING

Cyc-Arc. The "Cyc-Arc" Process of Automatic Electric Welding, L. J. Steele and H. Martin. Instn. Elec. Engrs. Jl., vol. 60, no. 305, Jan. 1922, pp. 136–157 and (discussion) 158–162, 14 figs. Detailed description of the processes, by which metals of widely differing character and section can successfully be welded electrically.

Steel Construction. Electric Welding Applied to Steel Construction, with Special Reference to Ships, A. T. Wall. Engineering, vol. 113, no. 2930, Feb. 24, 1922, pp. 241–244, 14 figs. Writer calls attention to various ways in which electric welding is being applied to ship construction, and indicates further possibilities in this connection for steel structures. Paper read before Instn. Mech. Engrs.

ELECTRIC WELDING, ARC

Cast Iron. Arc-welding of Cast Iron. Machy. (Lond.), vol. 19, no. 490, Feb. 16, 1922, pp. 593–596, 6 figs. Use and application of methods for welding cast iron by electric arc.

Practical Points. Practical Points in Arc Welding, J. A. Wilson. Am. Mach., vol. 56, no. 10, Mar. 9, 1922, pp. 357–358, 4 figs. Notes on keeping work clean; beveling edges; allowing for expansion and contraction; guarding against injury; making solid welds.

Refrigerating Machinery. Arc Welding of Refrigerating Machinery, A. M. Candy. Welding Engr., vol. 7, no. 2, Feb. 1922, pp. 21–23, 9 figs. Advantages in repair and production work. Paper read before Am. Soc. Refrig. Engrs.

ELECTRICAL MACHINERY

Manufacturing Plant. The Works of the General Electric Company at Witton. Engineering, vol. 113, no. 2928, Feb. 10, 1922, pp. 166–167, 4 figs. Recent extensions at Witton comprise new switchgear shops and shops for manufacture of standard sizes of electric motors, molded insulation works and enameling and plating shops, etc.

ELEVATORS

Motor Controller. Operation of a Drum-Type, Elevator-Machine Alternating-Current Motor Controller, William Zepernick. Power, vol. 55, no. 8, Feb. 21, 1922, pp. 295–298, 9 figs. Functions of different parts and circuits of a one-speed elevator controller. Tracing out circuits for one direction of machine.

Passenger, Safeguarding. Passenger Elevator Protection, J. J. Lamb. Power Plant Eng., vol. 26, no. 4, Feb. 15, 1922, pp. 231–234, 3 figs. Arrangement and safeguarding to prevent accidents and reduce fire hazard to a minimum.

EMPLOYEES' REPRESENTATION

Shop Committees. How Shop Committees Function Under Depression, Lionel D. Edie. Indus. Management, vol. 63, no. 2, Feb. 1922, pp. 92–95. Account of what happened to shop committees of Int. Harvester Co., and how these committees have handled lay-offs and wage reductions. Record includes wage cut of 20 per cent decided entirely by shop committees.

EMPLOYEES, TRAINING OF

Manufacturing. The Training of Workers in Manufacture, J. V. L. Morris. Am. Mach., vol. 56, no. 9, Mar. 2, 1922, pp. 320–322. Apprenticeship practices regarding indenture, age, payment and certificates. Public school substitutes. Evening, part-time and coöperative schools.

Methods. Making Industrial Improvements Permanent, Paul M. Atkins. Management Eng., vol. 2, no. 3, Mar. 1922, pp. 153–158, 4 figs. Through patient teaching based on written instructions. Two classes of employee instruction. Specific forms of training.

EMPLOYMENT MANAGEMENT

Eye Examinations. Better Work and More Work per Man Through Better Sight, E. LeRoy Ryer and Willard B. Fisher. Indus. Management, vol. 63, no. 2, Feb. 1922, pp. 111–117, 2 figs. Industrial eye examinations and their importance in management.

Principles Involved. Increasing Man Power Through Management, L. W. Olson. Indus. Management, vol. 63, no. 2, Feb. 1922, pp. 88–91. Writer discusses cardinal principles involved in management of men.

Testing Motormen. Psychological Tests for Motormen, Alfred Gradenwitz. Elec. Ry. Jl., vol. 59, no. 4, Jan. 28, 1922, pp. 143–146, 13 figs. Discusses physical and psychological tests which must be passed by candidates for position of motormen in Berlin.

ENGINEERING

Economics of. The Economics of Engineering, H. W. Pitt. Eng. Production, vol. 4, nos. 73 and 74 Feb. 23 and Mar. 2, 1922, pp. 173–175 and 197–199 Feb. 23: Deals with design economics; production and consumption cost; designing for a given market; standardization and accuracy as cost reducers; designing and costing. Mar. 2: Designer and consumer; production and factory economics; division of labor; economics of purchasing and of selling and using.

ENGINEERING SOCIETIES

German, Alliance of. The Alliance of the Engineering and Scientific Associations of Germany (Zusammenschluss der technisch-wissenschaftlichen Vereine Deutschlands). Gewerbefleiss, vol. 100, no. 12, Dec. 1921, pp. 344–346. Account of alliance of nearly all of the German technical and scientific societies into an organization known as Deutscher Verband (German Federation).

ENGINEERS

Licensing. Licensing and Engineering Ethics, C. E. Waddell. Professional Engr., vol. 7, no. 1, Jan. 1922, pp. 8–9. Status of the expert witness, contractor, manufacturer, salesman, college graduate and practicing engineer.

EVAPORATORS

Basic Principles. Evaporators—What They Are and How They Operate. Power, vol. 55, no. 8, Feb. 21, 1922, pp. 292–294, 3 figs. Writer seeks to present clear idea of basic principles of evaporators as used in power plants to produce distilled makeup water.

F

FACTORIES

Fire and Burglary Protection. Protection against Burglary in Factories by Means of Organization (Fabrikdiebstahlschutz durch Betriebsorganisation). H. Sauter. Betrieb, vol. 4, no. 7, Feb. 14, 1922, pp. 218–226, 16 figs. Describes organization of the Ludwig Loewe & Co., Berlin, which is said to greatly aid in detection of burglars and in prevention of theft.

Safety Arrangements in Factories (Sicherheitseinrichtungen in Fabrikbetrieben), R. Bügler. Betrieb, vol. 4, no. 7, Feb. 14, 1922, pp. 205–209, 20 figs. Describes electric installations and devices for protection against fire and burglary.

Vacuum Cleaning. Vacuum Cleaning Applied to Industrial Plants, Charles L. Hubbard. Factory, vol. 28, no. 3, Mar. 1922, pp. 285–288, 6 figs. Discusses applications in factories and selection of proper type of vacuum cleaner for given conditions.

FACTORY MANAGEMENT

See INDUSTRIAL MANAGEMENT.

FLIGHT

Soaring. A German View of Soaring Flight. Aeroplane, vol. 22, no. 1, Jan. 4, 1922, pp. 8–10, 4 figs. Discusses development of small sporting-type machines, development of new methods of light construction, and educational value of work done as tending to improve aeronautical construction generally.

Soaring Flight and Soaring Aircraft. Aviation, vol. 12, nos. 7 and 8, Feb. 13 and 20, 1922, pp. 195–198 and 224–225, 3 figs. Review of progress achieved in soaring flight and considerations of its practical possibilities.

Soaring Flight, Its Development and Prospects, Wm. Knight. Aerial Age, vol. 14, no. 24, Feb. 20, 1922, pp. 562–563, 8 figs. Describes Klemperer and Loessl gliders, and gives tables of distances and time of flights made.

FLUIDS

Adiabatic Liquefaction. Adiabatic Liquefaction of Fluids (La liquefaction adiabatique des fluides), Jean Villey. Comptes Rendus des Séances de l'Academie des Sciences, vol. 173, no. 26, Dec. 27,

1921, pp. 1453–1455. Confirms calculations by Brubat, that heat of vaporization of a liquid tends towards a limit L_0, not zero, at absolute zero, and that whatever the initial state, adiabatic expansion must always lead to liquefaction.

FLYING BOATS

Double-Pontoon Airplanes vs. Flying Boats versus Double-Pontoon Airplanes (Zur Frage: Flugboot oder Zweischwimmerflugzeug?), E. Meyer. Motorwagen, vol. 25, no. 2, Jan. 20, 1922, pp. 33–34. Describes Dornier commercial flying boat, type Do.Cs.II 1920, a single-engine, strutless all-metal monoplane with following characteristics: span, 17 m.; surface depth, 3 m.; height, 2.75 m.; length, 10.25 m.; supporting surface, 47 sq. m.; engine, 185-hp. BMW; weight empty, 1350 kg., loaded, 650 kg.; speed, 150 km. per hr., etc.

FOREMEN

Requirements and Training. Can Foremanship Help to Rebuild Profits? B. M. Nussbaum. Indus. Management, vol. 63, no. 3, Mar. 1922, pp. 155–159. Notes on cost saving and the foreman; foremen as advisers to directors; training and requirements of good formanship.

FOUNDRIES

Conveying and Mechanical Handling. Conveying and Mechanical Handling in the Foundry. Metal Industry (Lond.), vol. 20, no. 6, Feb. 10, 1922, pp. 123–127, 3 figs. Emphasizes necessity of keeping foundry handling costs at a minimum, and discusses various means to this end.

Dust Removal from Cleaning Room. Removing the Dust from the Casting Cleaning Room, C. C. Hermann. Indus. Management, vol. 63, no. 3, Mar. 1922, pp. 171–174, 3 figs. Design of suitable system requires competent consideration of (1) suction at hoods; (2) friction losses in piping; (3) selection of blower unit; (4) discharge resistance; (5) losses due to collector.

Gas Application in. The Application of Gas in the Foundry. Foundry Trade Jl., vol. 25, no. 286, Feb. 9, 1922, pp. 97–100, 7 figs. Describes way in which Mond gas generated at works of Nat. Gas Engine Co., Ltd., is fully utilized. Plant consists of a gas generator, scrubber, gas purifier, exhauster and pressure regulator.

Machine-Tool Industry. Machine Builder Erects Foundry, Pat Dwyer. Iron Trade Rev., vol. 70, no. 10, Mar. 9, 1922, pp. 683–686, 7 figs. Melting and crane equipment was installed sufficient to handle single castings up to 50 tons and daily normal output of 100 tons of castings. Details of new foundry of Toledo Machine & Tool Co., Toledo, Ohio.

Modern Designs. Modern Foundries, M. Fischer. Eng. Progress, vol. 3, no. 2, Feb. 1922, pp. 29–32, 14 figs. Principles governing construction of modern foundries as regards initial costs, enlargement, workmen, and auxiliary arrangements.

White Enameled Interior. Washable White Enameled Foundry Interior. Can. Foundryman, vol. 13, no. 2, Feb. 1922, pp. 17–19, 1 fig. Describes foundry of Waterous Engine Works Co., Brantford, Ont.

FREIGHT HANDLING

Container System. Container System Creates Freight Service. Ry. Age, vol. 72, no. 8, Feb. 25, 1922, pp. 475–476, 5 figs. Describes practice of Cincinnati, Lawrenceburg & Aurora. Inauguration of a demountable body or unit container system in conjunction with motor trucks, and establishment of a small off-track station for handling of these containers.

Containers Carry Freight in Cincinnati. Elec. Ry. Jl., vol. 59, no. 8, Feb. 25, 1922, pp. 315–318, 8 figs. An interurban electric railway without tracks downtown gives through freight service by containers which are carried on motor trucks within city and on electric cars for interurban run.

Electric Tractors and Trailers. Modern Methods of Handling Package Freight, G. Marks. Ry. Age, vol. 72, no. 8, Feb. 25, 1922, pp. 469–470. Use of electric tractors and trailers in freight houses, and savings effected on New Haven line. (Abstract.) Paper read before New Eng. R. R. Club.

Erie Railroad. Erie Adopts Direct Freight Delivery at New York. Ry. Age, vol. 72, no. 3, Jan. 21, 1922, pp. 233–234, 1 fig. Plan involves breaking bulk at Jersey City, N. J., and use of auto trucks, tractors and trailers and ferries.

FUELS

Gas. Burning Fuel Gases Efficiently, H. S. Watts. Iron Trade Rev., vol. 70, no. 9, Mar. 2, 1922, pp. 605–609, 2 figs. Combustion temperature and stack loss are important factors from standpoint of economy. Design and operation of gas burners and principles of continuous heating are discussed.

Fuel Gases and Their Use in Iron and Steel Plants, H. S. Watts. Assn. Iron & Steel Elec. Engrs., vol. 4, no. 2, Feb. 1922, pp. 97–126, 5 figs. Characteristics of gases; design and operation of gas burners; principles of continuous heating.

High-Ash Coal. Low-Ash Coal Not Always Desirable, S. W. Flagg. Power, vol. 55, no. 9, Feb. 28, 1922, pp. 328–330, 4 figs. Discussion of conditions under which it was found that coal with high ash content reduced stoker trouble.

Sawmill Refuse. Generating Power from Waste, H. S. Bastian. Elec. World, vol. 79, no. 8, Feb. 25, 1922, pp. 373–375, 5 figs. "Hogged fuel," or sawmill refuse, proves to be a valuable combustible in lumber-producing regions; care must, however, be exercised in firing if best results are to be obtained.

Vegetable Gas. The Gasification of Vegetable Wastes According to the Process of the German Gas Corporation, Hannover (Germany) (Vegetabilienvergasung nach dem Verfahren der Deutschen Gas-Akt.-Ges., Hannover). Wärme- u. Kälte-Technik, vol. 24, no. 1, Jan. 1922, pp. 5–7, 2 figs. Discusses gasification of tanbark waste, broken hemp stalks, cocoa-bean shells, olive-seed hulls, as well as the hulls of leguminous plants, and gives analyses and thermal values of vegetable gas.

[See also LIGNITE; OIL FUEL; PULVERIZED COAL.]

FURNACES, ANNEALING

Sheet and Tin Mill. Sheet and Tin Mill Furnaces, T. J. Costello and J. H. Knapp. Blast Furnace & Steel Plant, vol. 10, no. 2, Feb. 1922, pp. 141–144, 3 figs. Improvements in furnaces used for heating and annealing sheet and tin.

FURNACES, BOILER

Burners for Blast-Furnace Gas. Tests with Gas Burners on Boilers and Cowpers (Versuche mit Gasbrennern an Kesseln und Cowpern), Eduard Weymann. Stahl u. Eisen, vol. 42, no. 6, Feb. 9, 1922, pp. 215–221, 11 figs. Investigation of different burners for blast-furnace gas for heating of fire-tube boilers and Cowper stoves and description of their arrangement and operation. Comparison of test results. Behavior of burners with fluctuating gas pressures. Describes new American arrangement for regulation of air inlet with fluctuation of gas pressure.

Gas-Fired. The Economic Burning of Excess Gas (Die wirtschaftliche Verfeuerung von Ueberschussgas), M. Schimpf. Glückauf, vol. 58, no. 3, Jan. 21, 1922, pp. 72–76, 8 figs. Account of test carried out at a German mine with a Moll gas-fired furnace and gas-pressure regulator. Demonstrates with aid of numerical example savings which can be effected with use of a regulated gas pressure.

Low-Grade Fuel. The New Mechanical Bamag Furnaces (Die neuen mechanischen Bamag-Feuerungen), H. Pradel. Braunkohle, vol. 20, no. 30, Oct. 29, 1921, pp. 472–476, 5 figs. Describes forced-draft traveling grates and underfeed furnaces of the Berlin-Anhalt Machine Construction Corp., Dessau, for utilization of lignite.

FURNACES, FORGING

Types. Discussion of Forge Furnaces, Charles Longenecker. Forging & Heat Treating, vol. 8, no. 2, Feb. 1922, pp. 122–124. Discusses soaking pits, regenerative-type furnaces, non-regenerative type, and furnaces of small hearth area, pointing out possibilities for saving and increased efficiency with various classes of fuel.

G

GAS

By-Product. Value of By-Product Gas to Industry, H. Dobrin. Assn. Iron & Steel Elec. Engrs., vol. 4, no. 2, Feb. 1922, pp. 79–90 and (discussion) 91–96. Flame temperatures of various gases; use of by-product gas in glass, iron, boiler, and automobile works; furnace design; combustion.

Fuel. See FUELS, Gas.

GAS ENGINES

Manufacture of Parts. How Large Engine Parts Are Made, Pat Dwyer. Foundry, vol. 50, nos. 2 and 3, Jan. 15 and Feb. 1, 1922, pp. 66–73 and 114–119, 18 figs. Jan. 15: Molding practice at plant of Allis Chalmers Co., West Allis, Wis., in production of what are claimed to be largest gas engines in world. Feb. 1: Handling of large engine castings after they are made.

GAS PRODUCERS

Benoid Automatic. Benoid Gas Producer. Eng. Progress, vol. 3, no. 2, Feb. 1922, pp. 37–38, 2 figs. Arrangement, drive and operation of an automatically acting gas producer; properties of gas suitable for illuminating and heating purposes.

Coupled to Gas-Engine Plant. Some Observations on a Producer-Gas Power Plant, H. S. Denny. Engineering, vol. 113, nos. 2926, 2927 and 2928, Jan. 27, Feb. 3 and 10, 1922, pp. 119–122, 152–154, and 184, 10 figs. Account of investigation of large-capacity Mond gas-producer plant coupled up to gas-engine plant of equivalent size. Paper read before Instn. Mech. Engrs. For discussion, see no. 2928, Feb. 10, pp. 160–162.

GAS TURBINES

Economy. Economy and the Gas Turbine, Norman Davey. Engineer, vol. 133, no. 3451, Feb. 17, 1922, p. 177. Gives comparative analyses of gas-turbine cycles (heat absorption at constant pressure) working with common rotary compressor and with kinetic compressor. Writer maintains that gas turbine competes essentially with steam turbine. (Letter to editor.)

Efficiency, Determination of. Thermodynamic Bases for Determining Efficiency to be Expected from Gas Turbines, H. Schmulke. Mech. Eng., vol. 44, no. 3, Mar. 1922, pp. 187–190, 4 figs. Presents, among others, diagrams developed by W. Schüle showing process and efficiency of Holzwarth turbines. Translated from Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, no. 44, Nov. 4, 1921, p. 351.

GASES

Heat Transfer Between Liquids and. Rates of Absorption and Heat Transfer between Gases and Liquids, W. G. Whitman and J. L. Keats. Jl. Indus. & Eng. Chem., vol. 14, no. 3, Mar. 1922, pp. 186–191, 3 figs. Presentation of theory involved in liquid-gas interactions. Summary of Lewis' mathematical treatment with modifications. Verification of theory. Presentation of equations showing effect of operating variables on coefficients for various types of apparatus.

Specific Heat. The Specific Heats of Ammonia, Sulphur dioxide and Carbon dioxide, J. R. Partington and H. J. Cant. Lond., Edinburgh, and Dublin Philosophical Mag. & Jl. of Sci., vol. 43, no. 254, Feb. 1922, pp. 369–380, 2 figs. Experimental results of investigations carried out with object of obtaining reasonably accurate data for use in theoretical discussion.

GEAR CUTTING

Multiple Shaper. Develops Multiple Shaper for Internal Gears. Iron Age, vol. 109, no. 9, Mar. 2, 1922, pp. 592–593, 4 figs. Down-stroke model supplements previous machine of Stevenson Gear Co., Indianapolis; essential features retained.

Planing Spur Gears. Planing Large Spur Gears, Franklin D. Jones. Machy. (N. Y.), vol. 28, no. 7, Mar. 1922, pp. 529–532, 6 figs. Application of gear planers which cut gear teeth by reproducing shape of templet.

Tooth-Chamfering Machine. Gear Tooth Chamfering Machine. Machy. (Lond.), vol. 19, no. 488, Feb. 2, 1922, p. 558, 4 figs. Describes machine built by Parkinson & Son, Shipley. Effect of chamfer on engagement of gears.

Worm-Gear Generator. A New Worm Gear Generator. British Machine Tool Eng., vol. 2, no. 13, Jan.-Feb. 1922, pp. 439–445, 9 figs. Describes 12-in. worm-gear generator of Smith & Coventry, Ltd., Manchester.

GEARS

Bevel-Gear Testing Machine. The Saurer Bevel Gear Testing Machine. Engineering, vol. 113, no. 2930, Feb. 24, 1922, pp. 228–229, 9 figs. Bed of machine is heavy, circular casting, upon which a pair of sliding heads can be locked in any position, so that angle between axes of heads corresponds to that of bevels to be tested, a range from 52 to 150 deg. being obtainable.

Chain. The Application of Chain Gearing, H. T. Hildage. Can. Manufacturer, vol. 42, no. 2, Feb. 1922, pp. 31 and 51. When adaptable to certain needs; type of chain required; what it will cost; how much space it will occupy; how long it will last.

Friction. Friction Gearing, Chas. S. Pettit. Machy. (Lond.), vol. 19, no. 489, Feb. 9, 1922, pp. 567–569. Discusses frictional contact between driving and driven members; coefficient of friction; pressures of contact; variable-speed disc drives; cup and cone friction clutches; etc.

Herringbone. Standardization of Herringbone Gears, Am. Mach., vol. 56, no. 9, Mar. 2, 1922, pp. 329–330, 2 figs. Recommendations which are result of careful investigation by committee of Am. Gear Mfrs. Assn.

Hot-Rolling. Forming Gears by Hot Rolling, Reginald Trautschold. Iron Trade Rev., vol. 70, no. 6, Feb. 9, 1922, pp. 396–399, 6 figs. Independent application of power to die roll and gear blank and synchronization of their rotation are said to be factors contributing to success of gear-rolling processes.

Spiral Bevel. End Thrusts and Bearing Loads due to Spiral Bevel Gears. Machy. (Lond.), vol. 19, no. 488, Feb. 2, 1922, pp. 545–548, 4 figs. Discusses pinion-cut left-hand spiral, rotating clockwise; pinion-cut left-hand spiral, rotating counter-clockwise; pinion-cut right-hand spiral, rotating clockwise; and pinion-cut right-hand spiral, rotating counter-clock-wise.

GRINDING MACHINES

Plain. A New Precision Grinding Machine. Machy. (Lond.), vol. 19, no. 488, Feb. 2, 1922, pp. 532–534, 5 figs. Plain grinder with positive-acting table traverse and reversing mechanism.

H

HEAT PUMPS

Evaporators and. Experiences with Evaporators in Connection with Heat Pumps (Erfahrungen an Eindampfanlagen mit Wärmepumpe), E. Wirth. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 46, Nov. 12, 1921, pp. 1183–1186, 11 figs. Points out that as economy of evaporation with liquid concentration is based on a minimum consumption of power, it is necessary to carefully investigate all conditions influencing increase in temperature of vapor. Whereas until now investigations have been made only with regard to liquids with low boiling point, data are here given with heavier liquids. Account of author's experiences during several years with heat-pump operation.

HEATING

Central Producer-Gas Plant. Central Heating by Steam, Water or Gas, Samuel R. Lewis. Power, vol. 55, no. 7, Feb. 14, 1922, pp. 267–268. Central producer-gas plant with automatic gas-fired boilers in each building shows an estimated saving in initial investment of $173,000 and a reduction in annual operating expense of $14,700 over steam heating.

Gas. Possibilities of Gaseous Heating, H. H. Clark. Western Soc. Engrs. Jl., vol. 27, no. 2, Feb. 1922, pp. 51–56 and (discussion) 56–58, 5 figs. Relative combustion efficiency of the various gases assuming perfect combustion; comparison of costs of various fuels; comparison of gas and electricity for heating, power and light. Gives a number of charts.

HEATING, HOT-AIR

Reversed Heat Engine. The Reversed Heat Engine as a Means of Heating Buildings, T. B. Morley,

Engineer, vol. 133, no. 3450, Feb. 10, 1922, 145-146, 1 fig. Recapitulates and explains Lord Kelvin's proposal, made in 1852, of an indirect process employing a heat engine and a "warming machine" driven by engine, by means of which heat delivered to building might be much greater than heat of combustion of coal consumed. Discusses its theoretical possibilities and nature of difficulties to be overcome in its application.

HEATING, HOT-WATER

Thermometers for. Thermometers for Tenements with Hot-Water Heating (Wärmemesser für Mietswohnungen mit Warmwasserheizung), H. Wittfeld. Gesundheits-Ingenieur, vol. 45, no. 3, Jan. 21, 1922, pp. 25-28, 1 fig. Describes device for determining amount of total costs of heating which falls to each apartment according to the actual amount of heat consumed in order to do away with present method of determining this cost according to surface area of heated rooms.

HEATING, STEAM

Dry Air with. "Dry Air" with Central Heating (Trockene Luft bei der Zentralheizung), R. Gare. Wärme- u. Kälte-Technik, vol. 24, no. 1, Jan. 1922, pp. 4-5. Points out that not the absolute, but the relative moisture content changes with the heating of air as the absorptivity for steam increases; this change is the same in all heating systems, consequently the idea that central and especially steam heating "dries out" the air more than other heating systems is erroneous.

HEAVY-OIL ENGINES

Naphthalene. Naphthalene Engines (Moteurs à naphthaline), P. Maréchal. Nature, no. 2493, Jan. 14, 1922, pp. 22-23, 1 fig. Describes operation of a recent type in which fuel is vaporized by gasifying at low temperature, which makes engine run smoothly.

HELICOPTERS

Problems. Some Notes on the Helicopter, M. B. Sellers. Aviation, vol. 12, no. 8, Feb. 20, 1922, pp. 228-230, 3 figs. Elements of the problem, some experimental results, difficulties yet awaiting solution. N.A.C.A. Technical Note, No. 47, Apr. 1921.

HYDRAULIC TURBINES

Draft-Tube Designs. A Discussion of Draft-Tube Designs, Webster K. Ramsay. Mech. Eng., vol. 44, no. 3, Mar. 1922, pp. 171-176, 11 figs. With special reference to recent forms known as hydraucone regainer and spreading draft tube.

Flow in Conical Draft Tubes. Flow in Conical Draft Tubes of Varying Angles, George E. Lyon. Mech. Eng., vol. 44, no. 3, Mar. 1922, pp. 177-180, 7 figs. Account of investigation to determine velocity curves at several cross-sections of straight conical draft tubes.

Measuring Efficiency. New Methods for Measuring the Efficiency of Hydraulic Turbines (Note sur un nouveau procédé de mesure du rendement des turbines hydrauliques), L. Barbillion and A. Poirson. Bul. Technique de la Suisse Romande, vol. 48, no. 2, Jan. 21, 1922, pp. 19-21, 1 fig. Describes thermometric method by which losses are measured from temperature difference of water before and after passing turbine.

HYDROELECTRIC DEVELOPMENTS

Canada. A Review of Hydroelectric Progress in Canada. Can. Engr., vol. 42, no. 8, Feb. 21, 1922, pp. 241-244, 3 figs. Progress in development during 1921: 300,000 hp. installed in Dominion, with 177,000 hp. in Ontario and 90,000 hp. in Quebec.

Muscle Shoals, Ala. The Disposal of Muscle Shoals, R. S. McBride. Power, vol. 55, no. 8, Feb. 21, 1922, pp. 288-291, 4 figs. Notes on existing nitrate and power plants, Ford's offer and Secretary Weeks' objections, Alabama Power Co.'s offer. Author has endeavored to avoid expressing opinions, but has merely suggested basis for various arguments pro and con.

Ontario System. Hydroelectric System of Province of Ontario Investigated, W. S. Murray. Elec. World, vol. 79, no. 10, Mar. 11, 1922, pp. 471-474. In report made public by Nat. Elec. Light Assn., writer finds it inefficient, expensive and wasteful and that, in spite of all claims made for it, service from private utilities in United States and Canada is cheaper and better.

Shawinigan Falls, Canada. The New 41,000 Hp. Unit at Shawinigan Falls, Julian C. Smith. Eng. Jl. (Eng. Inst. Can.), vol. 5, no. 3, Mar. 1922, pp. 136-139, 7 figs. Describes design features of latest hydroelectric development of Shawinigan Water & Power Co.

St. Lawrence River. St. Lawrence Navigation and Power Investigation. Can. Engr., vol. 42, no. 3, Jan. 17, 1922, pp. 139-143, 1 fig. Details of double development plan as proposed by New York & Ontario Power Co. Suggestions based on 14 years' study of conditions in vicinity of Waddington. Proposed sites at Rapid du Plat and Long Sault.

HYDROELECTRIC PLANTS

High-Head. Highest Head Hydroelectric Power Installations of the World, A. T. Parsons. Jl. Electricity & Western, vol. 48, no. 4, Feb. 15, 1922, p. 155. Discusses limiting factors entering into design and construction of hydroelectric plants for very high heads.

Interconnection of Steam and. Michigan a Leader in Interconnection of Hydro and Steam Plants, Harry J. Burton and William W. Tefft. Elec. World, vol. 79, no. 7, Feb. 18, 1922, pp. 328-331, 2 figs. Twenty water-power and eleven steam stations joined by Consumers' Power Company's 140-Kv. transmission system. Bearing of hydro experience on Middle Western developments. How some problems have been solved.

Spain. Hydroelectric Installations in Spain, Horace F. Parshall. Engineering, vol. 113, no. 2928, Feb. 10, 1922, pp. 167-168. Installations of Barcelona Traction, Light & Power Co. (Abstract.) Paper read before Instn. Civ. Engrs.

I

ICE PLANTS

Electrically Operated. 300-Ton Ice Factory at Grimsby. Engineer, vol. 133, no. 3451, Feb. 17, 1922, pp. 171-173, 5 figs. Describes what is believed to be largest electrically operated direct-expansion ice-making plant in world, recently erected and put to work for Standard Ice & Cold Storage Co., Ltd., by Pluperfect Refrigeration Co., Ltd., Manchester, England.

Central Station Service in the Ice Industry, H. M. Jones. Ice & Refrigeration, vol. 62, no. 2, Feb. 1922, pp. 136-138. Electric drive for ice-making plants, power required; kind and size of motors; comparative cost of operating.

Railway. Establishing Icing Facilities on a Large Scale, W. C. Phillips. Ry. Age, vol. 72, no. 9, Mar. 4, 1922, pp. 533-534, 2 figs. System recently inaugurated on Southern Pacific and Union Pacific gives highly satisfactory results.

IMPACT TESTING

Endurance Tests. Impact Endurance Tests of Rods of Varying Cross-Section. Engineering, vol. 113, no. 2930, Feb. 24, 1922, p. 246. Describes endurance tests to which W. Muller and H. Leber, of the Material Testing Bureau at Darmstadt, Germany, have been submitting rods of varying cross-section. Translated from Zeit. des Vereines deutscher Ingenieure (pp. 1089-1094, 1921).

Notched-Bar Tests. Shock Test on Notched Bars (Zur Gesetzmässigkeit der Kerbschlagprobe), M. Moser. Stahl u. Eisen, vol. 42, no. 3, Jan. 19, 1922, pp. 90-97, 21 figs. Influence of thickness of test pieces on notched-bar impact values, relation of shock effect to unit of volume; characteristic of volume; influence of speed of blows; and of diameter of notch. Conclusions based on tests.

INDUSTRIAL MANAGEMENT

Forms. The Principles of Designing Forms, H. P. Losely. Management Eng., vol. 2, no. 3, Mar. 1922, pp. 158-160, 3 figs. Presents and discusses five principles governing design and use of forms.

Inventory Methods. How to Cut Cost Corners Through Inventory, W. M. Romig. Indus. Management, vol. 63, no. 2, Feb. 1922, pp. 86-87, 2 figs. How well-managed inventory methods help to stabilize profits.

Labor-Routine Chart. Labor Routine. Indus. Management, vol. 63, no. 3, Mar. 1922, pp. 176-177. Presents chart developed for Todd Dry Dock & Constr. Co. by William C. Bober showing how systems of routine may be charted to bring out each step.

Planning. Planning in Large Contract Plants, George H. Shepard. Machy. (N. Y.), vol. 28, no. 7, Mar. 1922, pp. 547-551, 13 figs. Cards and records used in planning and dispatching work.

Production Control. The Measurement of Human Work, Walter N. Polakov. Management Eng., vol. 2, no. 2, Feb. 1922, pp. 91-93, 1 fig. The Gantt graphic method of controlling production is claimed to be only one on a correct unit of measurement.

Production Organization. Organization of Production, J. W. Curtis. Eng. & Indus. Management, vol. 7, nos. 5 and 7, Feb. 2 and 16, 1922, pp. 127-130 and 187-191, 19 figs. Discusses use of charts, and organization in erection work. Presents scheme of organization of engineering department of a medium-size works. Drawing office progress chart.

Purchasing Policies. Stabilizing Profits through Proper Purchasing Policies, Park Mathewson. Indus. Management, vol. 63, no. 3, Mar. 1922, pp. 136-139. How purchasing executive should apply fundamentals of forecasting.

Reduced Force, Operating with. Operating a Factory with a Reduced Force, John C. Lease. Machy. (N. Y.), vol. 28, no. 7, Mar. 1922, pp. 533-535, 3 figs. Describes how factory was profitably operated at 30 per cent capacity.

Sales Organization. Sales Organization and Methods, Willard E. Freeland. Taylor Soc. Bul., vol. 6, no. 6, Dec. 1921, pp. 244-251 and (discussion) pp. 251-254. Second report of committee on sales questionnaire, purpose of which was to obtain information about form of organization of sales departments, extent to which engineering phases were recognized and scientific planning and scheduling attempted, and methods of control of important portions of work of distribution organization.

Standard Lot Quantities. Establishing Profitable Standard Lot Quantities, J. A. Bennie. Indus. Management, vol. 63, no. 3, Mar. 1922, pp. 167-169, 2 figs. How to determine order points for stock parts.

Time Study. See TIME STUDY.

INDUSTRIAL ORGANIZATION

Administration Problems. Works Organization, T. E. Pattinson. Eng. Production, vol. 4, nos. 70 and 71, Feb. 2 and 9, 1922, pp. 101-104 and 124-127, 18 figs. Deals mainly with problems which have been encountered in administration of a large works organization. Paper presented before Instn. Production Engrs. See also discussion in same journal, no. 72, Feb. 16, 1922, pp. 149-152.

Fundamentals. The Body, Soul and Spirit of Organization, B. A. Franklin. Indus. Management, vol. 63, no. 3, Mar. 1922, pp. 143-145. Discusses fundamentals underlying organizing for accomplishment.

Profit Margins, Reestablishing. Reestablishing the Profit Margins in the Edison Industries, Alfred Stuart Myers. Indus. Management, vol. 63, no. 3, Mar. 1922, pp. 131-135. Describes executive policies that successfully met problems of depression.

Profits, Stabilizing. Stabilizing the Profits of the Small Factory, Ernest Cordeal. Indus. Management, vol. 63, no. 3, Mar. 1922, pp. 146-149. Author points out necessity of constant attention to raw-material market, probable demand for product and stability of wage scales, and shows how useless any cost system may become unless it is intelligently followed up.

INDUSTRIAL RELATIONS

Antagonism of Capital and Labor. The Inevitable Antagonism Between Employers and Employees, C. E. Knoeppel. Management Eng., vol. 2, no. 3, Mar. 1922, pp. 143-148. Writer maintains that interests of capital and labor, instead of being mutual, are absolutely antagonistic; as factors in industrial life they are irreconcilable; they have every reason for staying apart; they have always fought, are fighting now, and will continue to fight. Discusses possibilities of future development of a mutuality of interests.

INTERNAL-COMBUSTION ENGINES

Castings for. Some Castings for Internal Combustion Engines, Ben Shaw and James Edgar. Foundry Trade Jl., vol. 25, no. 285, Feb. 2, 1922, pp. 83-87, 26 figs. Deals with patternmaking for crankcases, drawing board, and core-boxes.

Combustion in. Study of Combustion of Liquid Fuels in Internal-Combustion Engines, with Special Regard to Fuel and Exhaust-Gas Analysis (Beiträge zur Kenntnis der Verbrennung flussiger Brennstoffe in Motoren, unter besonderer Berucksichtigung der Brennstoff und Abgasuntersuchung), E. Terres, Fritz Wehrmann and L. Lueg. Zeit. für Elektrochemie, vol. 27, no. 17-18 and 19-20, 1921, Sept. 1 and Oct. 1, pp. 379-393 and 423-441, 33 figs. Results of tests carried out on a 4-cylinder 40-hp. Benz engine.

Fuels, Effect of. Effect of Different Fuels on the Operation of Internal-Combustion Engines (L'influence de l'emploi de combustibles différents sur le fonctionnement des moteurs à combostion interne), Henri Petit. Technique Automobile et Aerienne, vol. 12, nos. 113, 114 and 115, 1921, pp. 50-62, 72-87 and 97-115, 34 figs. No. 113: Results of experiments to determine power and efficiency of engine; energy contained in given fuel mixed with air; losses, proper conditions of combustion of various fuels, their calorific power; etc. No. 114: Relation between explosion and ignition temperatures; use of inert gases; maximum specific volume; etc. No. 115: Distribution of heat; starting engine; distribution of fuel in cylinders; volumetric efficiency; variable pressure engines, overcharged engines, and others. Gives numerous tables.

Hot-Bulb Marine. Internal Combustion Engine, J. J. Fasola. Inst. Mar. Engrs. Trans., vol. 33, Jan. 1922, pp. 583-628, (includes discussion) 10 figs. Fundamentals and other particulars relating to a modern hot-bulb marine engine.

[See also AIRPLANE ENGINES; AUTOMOBILE ENGINES; CARBURETORS; DIESEL ENGINES; GAS ENGINES; HEAVY-OIL ENGINES; OIL ENGINES.]

IRON, PIG

Desulphurization of. The Desulphurization of Pig Iron and Steel (Zur Frage der Entschwefelung von Roheisen und Stahl), Bruno Simmersbach. Chemiker-Zeitung, vol. 46, no. 8, Jan. 19, 1922, pp. 65-68. Notes on origin of sulphur in pig iron and steel and suggestions for its removal.

L

LABOR TURNOVER

Absenteeism. Absenteeism: a Quanitative Study, J. D. Hackett. Management Eng., vol. 2, no. 2, Feb. 1922, pp. 85-90. Factors from experience on causes, occurence, and duration of absenteeism and condition of absentees.

Unavoidable, Elements of. Elements of Unavoidable Labor Turnover, A. L. DeLeeuw. Management Eng., vol. 2, no. 3, Mar. 1922, pp. 137-142, 5 figs. It is maintained that labor turnover of whatever kind provides measure of management efficiency because its cost is an overhead expense.

LABORATORIES

Foundry. Keighley Laboratories, Limited. Foundry Trade Jl., vol. 25, no. 285, Feb. 2, 1922, pp. 75-80, 14 figs. Traces origin of laboratory and describes its equipment and recent research work carried out in connection with internal chill in gray-iron castings.

Laboratory for Malleable Iron Foundry. Iron Age, vol. 109, no. 10, Mar. 9, 1922, pp. 643-644, 3 figs. Equipment for running carbon, sulphur and manganese determinations facilitates control of product. Getting rid of heavy gases.

Industrial. Research Laboratories in Industrial Establishments of the United States. Nat. Research Council Bul., vol. 3, no. 16, Dec. 1921, 135 pp. List of laboratories arranged by firm names, with a subject classification, giving particulars as to research staff, research work and equipment in each case.

Originally compiled by Alfred D. Flinn, revised and enlarged by Ruth Cobb.

LATHES

Bed Guards. Durability in Machine Tools, P. V. Vernon. Eng. Production, vol. 4, no. 72, Feb. 16, 1922, pp. 153–154, 3 figs. Describes Herbert automatic lathe fitted with bed guards, introduced in 1910, and new model no. 11 hexagon turret lathe, embodying similar protective devices.

Fay, Machining on. Cutting the Production Cost of a Difficult Part, H. A. Loudon. Am. Mach., vol. 56, no. 10, Mar. 9, 1922, pp. 369–370, 6 figs. Describes machining of one of its own parts, the cam drum worm, by the standard Fay lathe.

Turret. A New Hexagon Turret Lathe. Engineer, vol. 133, no. 3450, Feb. 10, 1922, p. 160, 1 fig. Claimed to be an entirely new type. One of chief features is fact that scraped bed slides are completely covered by cast iron guards; another feature is manner in which all possible points of danger are guarded.

Motor-car Engine Production Work on Turret Lathes. Machy. (Lond.), vol. 19, no. 489, Feb. 9, 1922, pp. 570–573, 8 figs. Time-saving and cost-reducing methods for engine department of a motor-car plant.

LIGHTHOUSES

Aerial. Aerial Lighthouses. Aerial Age, vol. 14, no. 24, Feb. 20, 1922, pp. 564–565 and 561, 2 figs. Describes lighthouse being erected at Dijon in order to provide suitable guiding light for aerial routes between Paris and Algiers, Italy and Switzerland. Made by optical firm of Barbier, Bernard and Turenne, Paris.

LIGHTING

Artificial Daylight. Recent Improvements in the Sheringham Daylight, S. H. Groom. Illuminating Engr., vol. 14, no. 9, Nov. 1921, pp. 215–218, 4 figs. Principles upon which Sheringham daylight is based and recent improvements made.

Factory. Better Lighting Increases Production, Ward Harrison, O. F. Haas and F. W. Dopke. Iron Trade Rev., vol. 70, no. 9, Mar. 2, 1922, pp. 610–612, 2 figs. Account of investigation carried out by Dover Mfg. Co., Dover, Ohio, in its plant for purpose of obtaining further practical data showing effect of good lighting on efficiency of production.

Phototechnical Calculations. Phototechnical Calculations According to the Nomographic System (Lichttechnische Berechnungen in nomographischer Behandlungsweise), L. Bloch. Elektrotechnische Zeit., vol. 43, no. 3, Jan. 19, 1922, pp. 73–77, 8 figs. It is shown that practically all of more important calculations in lighting technology can be quickly and easily carried out with aid of nomographic methods.

LIGNITE

Dried, Specific Heat of. Determination of the Specific Heat for Dried Lignite and Lignite Briquettes (Bestimmung der spezifischen Warme fur getrocknete Braunkohle und Braunkohlenbriketts), J. Baudenbacher. Braunkohle, vol. 20, no. 28, Oct. 15, 1921, pp. 433–435, 1 fig. Results of test show that behavior of lignite in the absorption of heat is different from that of anthracite. Specific heat coefficient of German water-free lignite is found to be 0.49.

LOCOMOTIVES

Cylinders. Locomotive Cylinders. Ry. Gaz., vol. 36, no. 4, Jan. 27, 1922, p. 138, 2 figs. Describes method of L. B. Billinton, of Lond., Brighton & South Coast Ry., and results obtained, for renewing port faces of locomotive cylinders which have become prematurely worn to scrapping limits.

Development. What is Your Locomotive Policy? G. M. Basford. Central Ry. Club official Proc., vol. 30, no. 1, Jan. 1922, pp. 1086–1105 and (discussion) 1106–1117, 10 figs. Discusses necessity of formulating a policy for next 20 or 30 years in the development of locomotives for heavy freight, fast freight, way freight, fast passenger, slower passenger, branch-line passenger and freight, yard switching, and transfer.

Diesel-Engined. Direct Drive Diesel-Air Locomotive, W. S. Burn. Eng. Rev., vol. 35, no. 7, Jan. 1922, pp. 221–225, 1 fig. Describes horizontally opposed-piston type of engine, working in conjunction with two separate crankshafts, each being connected by two driving rods at 90 deg. to a jackshaft, and thence to wheels by coupling rods; air system, water-cooling system, and other details of design. Paper read before North-East Coast Instn. of Engrs. & Shipbuilders.

German and Austrian. The Most Modern Types of Former Austrian and German Locomotives Added to the Rolling Stock of the Italian State Railways (I piu moderni tipi di locomotive Ex-Austriache ed Ex-Germaniche, entrate a far parte del parco materiale delle ferrovie dello stato). Industria, vol. 35, nos. 18, 20 and 21, Sept 30, Oct. 31 and Nov. 15, 1921, pp. 402–407, 445–448 and 466–469, 12 figs. Sept. 30: Describes Austrian six-wheel switcher, Prairie and Mogul types, and Prussian ten-wheeler superheater type. Oct. 31: Describes eight-wheel switcher locomotive, a hump engine, and some Mastodon types Nov. 15: List of Austrian and German locomotives added to state railway.

Mikado and 8-Wheel. Mikado Locomotive for the Greenbrier & Eastern Railroad and Eight-Wheel Type Locomotive for the Dayton Goose Creek Railroad. Ry. & Locomotive Eng., vol. 35, no. 2, Feb. 1922, pp. 42–43, 2 figs. Describes Mikado 2–8–2, with tractive effort of 45,750 lb., and eight-wheel 4–4–0 type, with tractive effort of 13,770 lb., Built by Baldwin Locomotive works. See also Ry. Rev., vol. 70, no. 7 Feb. 18, 1922, pp. 213–214, 2 figs.

Northern Pacific Ry. Extensive Order of New Locomotives for the Northern Pacific Railway Company. Ry. & Locomotive Eng., vol. 35, no. 2, Feb. 1922, pp. 35–36, 3 figs. Describes Pacific type 4–6–2, Mikado type 2–8–2, and Mallet type 2–8–8–2, built by Am. Locomotive Co., with tractive efforts of, respectively, 41,900 lb., 57,100 lb., and 105,100 lb.

Ownership and Operation. Factors in the Business of Owning Locomotives, C. B. Peck. Ry. Age, vol. 72, no. 8, Feb. 25, 1922, pp. 471–474, Discusses coöperation between locomotive power and operating departments in designing and operating to secure economy. Paper read before Western Ry. Club.

Rebuilt. Operating Results Show Savings by Rebuilt Power, H. F. Grewe. Ry. Age, vol. 72, no. 7, Feb. 18, 1922, pp. 423–424, 2 figs. Gives locomotive data comparative mileages and expenses; operating costs.

The Passing of the Cross-Compound. Ry. Rev., vol. 70, no. 8, Feb. 25, 1922, p. 265, 2 figs. Describes conversion of a number of ten-wheel type cross-compound locomotives into simple locomotives of same type equipped with superheaters and piston valves.

Shay Geared. Shay Geared Locomotives for Mountain Roads. Ry. Mech. Engr., vol. 96, no. 2, Feb. 1922, pp. 75–76, 3 figs. 150-ton locomotive of Shay geared three-truck type with gear ratio of 1 to 2.45; for Greenbriar, Cheat & Elk Railroad. Comparison with heavy Mikado.

Speed Indicators. The Telco Locomotive Speed-Indicator and Recorder. Engineering, vol. 113, no. 2927, Feb. 3, 1922, pp. 131–133, 27 figs. Describes instrument constructed by Hasler Telegraph Works, London, having an ordinary clock movement which gives actual time and which is combined with gear producing a time record; also a distance counter, and speed-recording gear.

Steam-Turbine. The First Steam Turbine Locomotive. Ry. Mech. Engr., vol. 96, no. 2, Feb. 1922, pp. 69–70, 3 figs. Describes locomotive designed by Belluzzo, in 1908; maximum rotative speed of turbines was 2400 r.p.m. at 28 m.p.h.

Turbine Characteristics and Design of Turbo-Locomotives. Ry. Mech. Engr. vol. 96, no. 2, Feb. 1922, p. 61. Editorial discussing difficulties that must be overcome to apply the turbine to locomotives.

Zoelly Turbine Locomotive for Swiss Federal Railways. Ry. Mech. Engr., vol. 96, no. 2, Feb. 1922, p. 70. Describes new design of Dr. Zoelly, of Escher, Wyss & Co., Zurich, Switzerland. A 4–6–0 type locomotive has been converted from a standard type with usual reciprocating steam engine to turbine-driven engine. Turbine is designed for speed of 8000 r.p.m. or $48\frac{1}{2}$ m.p.h.

LUBRICATING OILS

Airplane Engines. Paraffin viz. Naphthene Base Oils. Sci. Lubrication, July 1921, pp. 5–8 and 13, 4 figs. Describes tests made for purpose of deciding various questions regarding lubrication of aeronautic engines with oils from Texas, Pennsylvania, and oils compounded with graphite.

Cutting Fluids. Cutting Fluids, Eugene C. Bingham. U. S. Bur. of Standards Technologic Papers, no. 204, Dec. 20, 1921, pp. 35–76, 8 figs. Used both to cool and lubricate. When lubrication is more important, it is generally recognized that fatty oils are superior to mineral oils, though reason has never been clearly explained. Evidence appears to be that value of fatty oils is due to their residual valence or acidity which causes their adhesion to metal to be greater than is case with mineral oils. Points out that it may yet be possible to synthesize an oil which has all of virtues of lard oil without its defects.

Dilution. Dilution of Crank Case Oil, C. M. Larson. Sci. Lubrication, Oct. 1921, pp. 13–15, 2 figs. Dilution of motor oils and possible means of preventing or correcting this condition in immediate future. Suggests that new instruments recently developed for detecting dilution be used by motorists, and that motors be drained as soon as instruments show mixture in crankcase has reached dangerous condition

Light Force-Feed. Endurance Tests of Force Feed Oils, J. G. O'Neill. Sci. Lubrication, Aug. 1921, pp. 5–10, 10 figs. Results obtained from endurance test of oils to ascertain service obtained from light force-feed lubricating oils when used in a force-feed lubrication system. Character of changes which take place in these oils under severe service conditions. Reprinted from Jl. Am. Soc. Naval Engrs., May 1921

Tests. Comparative Lubricating Engineering. Sci. Lubrication, Oct. 1921, pp. 20–22. Describes tests made to bring out relative lubricating qualities of various oils and tests made to determine most satisfactory and efficient lubricant for elevator worm gears.

Viscosity. Lubrication and Lubricants, Leonard Archbutt. Soc. Chem. Industry Jl., vol. 40, no. 24, Dec. 31, 1921, pp. 287T–293T. Discusses theory of viscous lubrication; measurement and expression of vicosity; effect of pressure on viscosity and density; solid contact friction; oiliness and its measurement; thickness of lubricating films; solid lubricants.

How Variation of Temperature Affects Viscosity of Lubricating Oils, W. F. Osborne. Power, vol. 55, no. 11, Mar. 14, 1922, pp. 420–421, 1 fig. Includes chart showing how viscosities vary with temperature.

LUBRICATION

Lubrication Engineering. The Status of Lubrication Engineering, W. H. Bailey. Sci. Lubrication, Oct. 1921, pp. 5–7. Discusses conservation of lubricants and liquid fuels, and basis from which these commodities are derived. Outlines purposes of Am. Soc. Lubricating Engrs.

Thickness of Oil Films in Bearings. The Thickness and Resistance of Oil Films in High Speed Bearings, Gerald Stoney. R. O. Boswall and J. Massey. Engineering, vol. 113, no. 2931, Mar. 3, 1922, pp. 249–250, 7 figs. Account of experimental investigation carried out during 1921 at College of Technology, Manchester, England for purpose of determining actual thickness of oil film or of discovering in what way this thickness changes with variations in load, rubbing speed and viscosity.

M

MACHINE GUNS

Patents for Inventions. Ordnance and Machine Guns. Abridgments of Specifications, Period—A.D 1909–15, class 92 (ii), 1921, 355 pp. Patents for inventions.

MACHINE SHOPS

British. A Bradford Engineering Works. Engineer, vol. 133, no. 3452, Feb. 24, 1922, pp. 210–212, 10 figs. partly on p. 214. Describes works of Cole, Marchent and Morley for manufacture of steam engines, Diesel engines, etc.

British Machine Tool Works. British Machine Tool Eng., vol. 2, no. 13, Jan.-Feb. 1922, pp. 428–431, 3 figs. Describes works of Kendall & Gent, Ltd., Gorton, Manchester.

Famous British Works. Eng. Production, vol. 4, no. 71, Feb. 9, 1922, pp. 122–123, 5 figs. Describes works of Greenwood & Batley, Ltd., Leeds for construction of metal-making, hydraulic, electric, turbine and textile machinery.

Famous British Works. Eng. Production, vol. 4, no. 73, Feb. 23, 1922, pp. 170–172, 6 figs. Describes works of Worthington-Simpson, Ltd., Newark-on-Trent, for manufacture of all types of pumping machinery.

Famous British Works. Eng. Production, vol. 4, no. 74, Mar. 2, 1922, pp. 194–196, 6 figs. Describes works of Blackstone & Co., Rutland Engineering Works, Stamford, for manufacture of oil engines and agricultural machinery.

MACHINE TOOLS

Anti-Slip Devices. Anti-Slip Devices Save Time and Money, Fred Horner. Can. Machy., vol. 27, no. 8, Feb. 23, 1922, pp. 19–20, 8 figs. Positive stops to prevent sliding; serration on tool face; anti-slip thrust screws; etc.

Electric Drive for Reversing. Electric Drive for Reversing Machine Tools, A. L. Harvey. Am. Mach., vol. 56, no. 10, Mar. 9, 1922, pp. 371–373. Notes on reversing mechanisms; dynamic braking and "plugging!" power consumed in reversing; effect of reversing on production; variation in power requirements.

MALLEABLE CASTINGS

Reactions in Malleablizing. Studies Reactions in Malleablizing, Arthur Phillips and E. S. Davenport. Foundry, vol. 50, no. 5, Mar. 1, 1922, pp. 185–194, 49 figs. Describes results of experiments showing effect of different temperatures and length of anneal.

MARINE BOILERS

Dyson. The Dyson Boiler, H. G. Cooper. Am. Soc. Naval Engrs. Jl., vol. 34, no. 1, Feb. 1922, pp. 33–55, 16 figs. Describes boiler and tests made at Fuel Oil Testing Plant of Phila. Navy Yard. It is believed that this boiler would prove a particularly satisfactory steam generator for capital ships.

METALLOGRAPHY

Etching. New Etching Method Develops Figures Ascribed to the Influence of Force, Ad. Fry. Forging & Treating, vol. 8, no. 2, Feb. 1922, pp. 99–104, 19 figs. Discusses nature and procedure of etching, and origin and nature of force influence figures. Translated from Stahl und Eisen, Aug. 11, 1921.

METALS

Calorizing. Calorizing, Arthur V. Farr. Engrs., Soc. West. Pa. Proc., vol. 37, no. 6, July 1921, pp. 331–340 and (discussion) pp. 341–343. Description of calorizing based upon standard methods as practiced under General Elec. Co.'s patent rights.

Colloidal State. Colloidal State in Metals and Alloys—III and IV, Jerome Alexander. Chem. & Met. Eng., vol. 26, nos. 4 and 5, Jan. 25 and Feb. 1, 1922, pp. 170–172 and 201–207, 11 figs. Jan. 25: White metal and brass. Feb. 1: Iron and Steel. Paper read before Am. Inst. Min. & Met. Engrs.

Failure Due to Internal Stress. The Failure of Metals Through the Action of Internal Stress Irregularities with Special Reference to Tool Steels, J. Neill Greenwood. Faraday Soc. Trans., vol. 17, part 1, no. 49, Dec. 1921, pp. 123–138, 6 figs. Investigation of basic reasons for failures and measures for minimizing their occurences. Bibliography.

Heat Treatment. Heat Treatment of Metals (Les traitements thermiques des métaux), R. Panaud. Outillage, vol. 243, no. 3, Jan. 21, 1922, pp. 73–75, 13 figs. Tempering baths; temperature and methods of tempering and effect on steel and other metals.

Tests for Automotive Industries. Correlation Between Metallurgical and Service Tests, Walter Rosenhain. Automotive Industries, vol. 46, no. 10, Mar. 9, 1922, pp. 566–568. Discusses need for greater coöperation between metallurgical and automotive engineers with a view to developing tests, result of which can be used with greater certainty of success in selecting most suitable metals for various purposes.

Thermal Expansion. Thermal Expansion of Nickel, Monel Metal, Stellite, Stainless Steel, and Aluminum, Wilmer H. Souder and Peter Hidnert. U. S. Bur.

of Standards Sci. Papers, no. 426, Dec. 17, 1921, pp. 497-519, 10 figs. Data on thermal expansion of 29 samples are presented, all of which, except stainless steel, were examined from room temperature to about 600 deg. cent. Samples of stainless steel were heated from room temperature to 900 deg. cent.

METRIC SYSTEM

Russia. The Metric System in Russia (Le système métrique en Russie), Leopold Reverchon. Nature, no. 2491, Dec. 31, 1922, pp. 427-428. Discusses degrees adopting metric system and gives table of equivalents.

MILLING CUTTERS

Top and Side Rake. Formed Milling Cutters and Hobs with Top and Side Rake, Harry E. Harris. Machy. (N. Y.), vol. 28, no. 7, Mar. 1922, pp. 527-528, 2 figs. Summarizes chief advantages of providing a hook on hob and cutter teeth.

MILLING MACHINES

Locomotive Bar Frames. Profile Milling Locomotive Bar Frames. Machy. (Lond.), vol. 19, no. 490, Feb. 16, 1922, pp. 600-601, 5 figs. Describes machine developed by Ernst Schiess, of Dusseldorf, with object of completely machining locomotive bar frames of about 4 in. in thickness from solid slab as furnished by rolling mills.

MOLDING MACHINES

Automobile Foundries. Modern Molding Machines in Foundries of Automobile Plants (Neuzeitliche Formmaschinen in Giessereien der Automobil-Industrie), Oskar Redeutz. Motorwagen, vol. 25, no. 3, Jan. 31, 1922, pp. 45-53, 26 figs. Describes molding machines constructed by the Richard Kindler Foundry Machine Works, Kirchheim-Teck, Germany, for automobile industry.

Hydraulic Jar-Ramming. French Molding Methods Are Rapid. Foundry, vol. 50, no. 4, Feb. 15, 1922, pp. 153-155, 7 figs. Describes new jar-ramming machine employing hydraulic principle.

Roll-Over. A German Roll-Over Molding Machine (Eine deutsche Umrollformmaschine), U. Lohse. Stahl u. Eisen, vol. 41, no. 52, Dec. 29, 1921, pp. 1889-1892, 7 figs. Notes on development by Pridmore and Tabor, followed by detailed description of design and manipulation of new machine by firm of Alfred Gutmann, Altona-Ottensen, use of which is especially recommended for molds of small and medium size, but of considerable height.

MOLDING METHODS

Pattern and Molding Plates. The Production of Pattern and Molding Plates (Aus der Praxis der Modell- und Formplattenherstellung), Ferd. Brobeck. Zeit. für die gesamte Giessereipraxis, vol. 43, nos. 1 and 2, Jan. 7 and 14, 1922, pp. 1-3 and 19-21, 26 figs. Purpose and use of patterns and molding plates, production of metal patterns. Includes schematic table showing working method of different types of molding machines in separating of pattern and sand.

Roll Methods. Diverse Methods of Roll Molding, R. H. Palmer. Foundry, vol. 50, no. 4, Feb. 15, 1922, pp. 159-163, 16 figs. Rolls cast in solid chills swung on supporting columns, some poured on end and others on side, various methods of gating are described.

MONEL METAL

Uses and Properties. Some Typical Uses and Properties of "Monel" Metal, Edwin S. Wheeler and Robert J. McKay. Engrs.' Soc. West Pa. Proc., vol. 37, no. 6, July 1921, pp. 311-324 and (discussion) pp. 325-330. Deals with occurrence and metallurgy; typical properties, typical and special uses.

MOTION PICTURES

Wasteful Methods, Showing. Films Reduce Losses from Scrap, Winthrop G. Hall. Iron Trade Rev., vol. 70, no. 10, Mar. 9, 1922, pp. 681-682. Moving pictures showing wasteful methods of employees prove effective means of curbing carelessness in handling materials in wire plant. Factors to be considered in filming industrial scenes. (Abstract.) Paper read before Worcester (Mass.) section of Am. Soc. Mech. Engrs.

MOTION STUDY

See POLISHING, Metal; TIME STUDY, Motion Study and.

MOTOR BUSES

Delaware, Maryland and D. C. The Bus in Northern Dixie. Elec. Ry. Jl. (Bus Transportation), vol. 59, no. 6, Feb. 11, 1922, pp. 93-102, 3 figs. Deals with conditions surrounding highway motor-bus operation and regulations prescribed in Delaware, Maryland and District of Columbia.

Eight-Wheel. Eight Wheels Improve Riding Qualities. Elec. Ry. Jl. (Bus Transportation), vol. 59, no. 6, Feb. 11, 1922, pp. 121 and 123, 4 figs. Describes new Californian bus. Has double-axle construction at both front and rear so that virtually it has two trucks. Front four wheels steer in unison; drive to four rear wheels is through two sets of worm and gear axles.

Local Railway Service. A Gasoline Motor Bus for Local Railway Needs (Automotrice à essence et à deux essieux pour chemins de fer d'intérêt local), G. Tartary. Génie Civil, vol. 80, no. 5, Feb. 4, 1922, p. 115, 1 fig. Describes new car seating 16 passengers, put in service by Deux-Sevres Tramway Co.

Snow Removal for. Fighting Snow on Suburban Routes. Elec. Ry. Jl. (Bus Transportation), vol. 59, no. 6, Feb. 11, 1922, pp. 103-104, 4 figs. Use of passenger buses with plows attached, for clearing snow.

Transportation. Putting the Motor Bus and Trolley Together to Build Service, H. W. Grant. Elec. Ry. Jl. (Bus Transportation Section), vol. 59, no. 2, Jan. 14, 1922, pp. 1-4, 7 figs. Describes linking up of interurban by means of motor buses in Puget Sound district in Washington.

MOTOR SLEDS

Design. The Problem of Motor Sleds (Das Problem des Motorschlittens), H. Schiebler. Motorwagen, vol. 24, nos. 35 and 36, Dec. 20 and 31, 1921, pp. 767-775 and 787-795, 42 figs. Desiderata for structural requirements, technical evaluation of snow, that is, its resistivity and friction coefficients under varying conditions. Description of electric-motor-driven trial sled, and results of tests.

MOTOR TRUCKS

Double-Reduction Axles. New Double Reduction Truck Axle. Automotive Industries, vol. 46, no. 8, Feb. 23, 1922, pp. 458-459, 2 figs. Describes new double-reduction design by John Thomson Press & Mfg. Co.

Steam. 5-Ton Steam Wagon with Uniflow Engine. Engineering, vol. 113, no. 2928, Feb. 10, 1922, pp. 162-163, 23 figs. partly on supp. plate. Describes tipping model embodying the Atkinson uniflow engine and auxiliary tipping engine, which can lift body and bring it back into position in two minutes.

MOTORCYCLES

Olympia Exhibition. The Motor Cycle Show. Automobile Engr., vol. 12, no. 159, Jan. 1922, pp. 13-19, 24 figs. Discusses machines at exhibition held at Olympia, Nov. 28 to Dec. 3.

O

OFFICE MANAGEMENT

Cutting Clerical Cost. Cutting the Clerical Cost, Henry Anson Piper. Indus. Management, vol. 63, no. 2, Feb. 1922, pp. 119-124, 7 figs. Planning procedure for plant offices in large organizations.

Scientific. The Application of the Principles of Scientific Management to the Office, William Henry Leffingwell. Bul. of Taylor Soc., vol. 7, no. 1, Feb. 1922, pp. 2-24 and (discussion) 24-26, 13 figs. Discusses planning and control, standardization, investigation and research, inspection and maintenance of quality, scientific office arrangement, etc.

OIL ENGINES

Scott-Still. A New Development in Marine Propulsion. Engineering, vol. 113, no. 2928, Feb. 10, 1922, pp. 177-178. Includes report by H. Riall Sankey on series of trials on Scott-Still engines for a Holt vessel, and gives details of engines.

Still Engine Developments. Engineer, vol. 133, nos. 3451 and 3452, Feb. 17 and 24, 1922, pp. 180-182 and 204-207, 20 figs. Includes full test of report by H. Riall Sankey on tests carried out on Still engine; and review of paper read by Archibald Rennie before Instn. of Engrs. & Shipbuilders in Scotland, giving particulars of the Scott-Still experimental unit.

OIL FUEL

Competition with Coal. Why Fuel Oil Must Continue to Compete with Coal, E. J. Billings. Power, vol. 55, no. 11, Mar. 14, 1922, pp. 417-419. Points out that fair comparison of fuel oil with coal cannot be made on basis of B.t.u. alone. Allowance must be made for higher efficiency and reduced operating expenses.

Gasification System. A System for Complete Fuel Gasification. Automotive Industries, vol. 46, no. 9, Mar. 2, 1922, pp. 509-510, 2 figs. Involves use of device for mechanical agitation of mixture, retort for heating entire charge above vaporization temperature of least volatile elements, and means for admixture of small quantities of exhaust gas to prevent detonation.

Vaporization. A Discussion of Present Methods of Fuel Vaporization, N. Julien Thompson. Automotive Industries, vol. 46, no. 9, Mar. 2, 1922, pp. 515-517, 2 figs. Preparation of fuel-air mixtures for combustion prior to admission to cylinder.

OILS

Linseed, Vanadium Driers for. Vanadium Compounds as Driers for Linseed Oil, F. H. Rhodes and K. S. Chen. Jl. Indus. & Eng. Chem., vol. 14, no. 3, Mar. 1922, pp. 222-224, 2 figs. Describes vanadium driers possessing certain advantages not shown by lead, manganese, or cobalt driers in common use, which should prove very satisfactory in preparation of certain types of paint and varnish.

OPEN-HEARTH FURNACES

Design. Open-Hearth Furnace Design, A. D. Williams. Iron Age, vol. 109, no. 9, Mar. 2, 1922, pp. 577-579, 3 figs. Calculations for hearth area, depth of metal, incline of parts and velocity of gases.

OSCILLOSCOPE

Operation. The Oscilloscope. Motor Transport, vol. 34, no. 883, Jan. 30, 1922, pp. 123-124, 3 figs. Describes invention by means of which it is possible to examine any fast-running machinery either as if it were running at 1/100 of its actual speed, or, at will, as if it were stationary.

OXY-ACETYLENE CUTTING

Under Water. Submarine Cutting Torch Under Water, Robert G. Skerrett. Iron Age, vol. 109, no. 10, Mar. 9, 1922, pp. 637-639, 5 figs. Broken siphon pipe burned off by electric torch under 50 ft of water. Discusses American progress in submerged metal cutting.

OXY-ACETYLENE WELDING

Blowpipe Investigation. An Investigation of Oxy-acetylene Welding and Cutting Blowpipe, with Especial Reference to Their Design, Safety, and Economy in Operation, Robert S. Johnston. U. S. Bur. of Standards Technologic Papers, no. 200, Dec. 28, 1921, pp. 3-108, 71 figs. Apparatus from 14 of most prominent manufacturers were tested under standardized conditions. None of commercial cutting blowpipes procurable appear to be designed according to definite theory and none are efficient in cutting metal of all thicknesses, none were correctly designed, nor free from flash-back phenomena. With properly designed welding blowpipe, it is believed that satisfactory fusion welds may be made.

Explosions, Prevention of. Dangers from the Use of Acetylene Gas and in Oxy-Acetylene Welding. Eng. & Indus. Management, vol. 7, no. 7, Feb. 16, 1922, pp. 192-193. Precautionary methods are given which should be observed by all employed in welding work. Deals with explosions in generator houses; high-pressure systems, and care of cylinders. Based on official memorandum issued by Factory Department of British Home Office.

P

PAPER MANUFACTURE

Load Regulator for Pulp Grinders. Automatic Load Regulator for Motor-Driven Pulp Grinders, W. H. Artz. Chem. & Met. Eng., vol. 26, no. 8, Feb. 22, 1922, pp. 367-369, 4 figs. Describes apparatus, its operation, and advantages.

Process and Machinery. Paper Making and Paper Making Machinery, Ellsworth Sheldon. Am. Mach., vol. 56, no. 9, Mar. 2, 1922, pp. 317-319, 6 figs. Forest is principal source of raw material. Process is continuous from grinding wood to winding finished sheet of paper.

Southern Pine Refuse. The Manufacture of Paper and By-Products from Southern Pine Refuse, Joseph H. Wallace. Worcester Polytechnic Inst. Jl., vol. 25, no. 2, Jan. 1922, pp. 65-79, 3 figs. Discusses manufacture of chemical fiber suitable for Kraft wrapping or book paper and test board by-product manufacture of naval stores; destructive distillation of trash; improvement of lands.

PIPING

Air-Pressure Drop Through. Air Pressure Drop Due to Small Pipe, W. A. Shmidheiser. Power Plant Eng., vol. 26, no. 4, Feb. 15, 1922, pp. 234-235, 1 fig. Describes experiment made to determine air pressure drop through $1^1/_2$-in. pipe.

PISTON RINGS

Design and Uses. The Piston Ring—Lilliputian in Size, Giant Among Parts in Technical and Commercial Importance, Morris A. Hall. Raw Material, vol. 5, no. 1, Feb. 1922, pp. 13-18, 10 figs. Discusses design, forms, and uses.

Locomotive. The "Rowan" Type of Piston Rings For Locomotives. Ry. Gaz., vol. 36, no. 4, Jan. 27, 1922, p. 137, 1 fig. Describes rings patented by William Rowan, of Belfast.

PISTON RODS

Packing for High-Pressure. Packing a Rod For 500,000 Lbs. Pressure, P. W. Bridgman. Power House, vol. 15, no. 3, Feb. 5, 1922, pp. 25-27, 4 figs. Describes principle of packing and some details of its application. Results of high-pressure experiments.

PISTONS

Manufacturing Plant. A Piston Manufacturing Plant, G. M. Ellis. Western Machy. World, vol. 13, no. 2, Feb. 1922, pp. 53-55, 7 figs. Describes plant of W. H. Jahns at Los Angeles; methods and equipment used.

PLATES

Rectangular, Bending of. The Bending of a Rectangular Plate Supported on All Sides and Subjected to a Single Load (Ueber die Biegung der allseitig unterstützten rechteckigen Platte unter Wirkung einer Einzellast), S. Timoschenko. Bauingenieur, vol. 3, no. 2, Jan. 31, 1922, pp. 51-54, 3 figs. Explains how to solve problem of deflection of rectangular plate braced on two opposite sides and supported on the two other sides.

POLISHING

Metal, Motion Study in. Motion Study in Metal Polishing, E. Farmer and R. S. Brooke. Eng. & Indus. Management, vol. 6, no. 26, Dec. 29, 1921, pp. 738-742, 3 figs. Experiment with a wattmeter on process of roughing.

POWER PLANTS

Design. Developments in Power Station Design. Engineer, vol. 133, nos. 3450 and 3552, Feb. 10 and 24, 1922, pp. 148-150, 6 figs. and 201-204, 5 figs. Feb. 10: Describes Usco air heater of Underfeed Stoker Co., and the Howden air heaters for marine work. Feb. 24: Notes on high-pressure steam turbines.

European Practice. European Practices Tend Toward Greater Economy, A. Dyckerhoff. Elec. World, vol. 79, no. 9, Mar. 4, 1922, pp. 421-424, 6 figs. Standardization of equipment and grouping of related activities. Waste-heat boilers, gas turbines, large mercury rectifiers and novel frequency changer. Shunt motors for shears. Power-factor correction.

nstructing Operators. Instructing Power-Plant Operators, J. A. MacMurchy. Power, vol. 55, no. 7, Feb. 14, 1922, pp. 260-262. Problems of making

operator familiar with equipment for which he is responsible. Methods of providing proper instructions.

PRESSES

Notching. Notching Press for Armature Plates and Segments Engineer, vol. 133, no. 3451, Feb. 17, 1922, p. 188, 2 figs. Constructed with object of providing machine wherehy armature plates or segments thereof may be notched, internally or externally, in accurate and continuous manner.

Safety Devices. Safety Devices for Power Presses. Machy. (Lond.), vol. 19, nos. 474 and 487, Oct. 27, 1921 and Jan. 26, 1922, pp. 96–99 and 523–525, 16 figs. Oct. 27: Various types of gate guards. Jan. 26: Deals with gate, stationary and sliding guards, provided for power press equipment of Cleveland Metal Products Co.'s plant, Cleveland, Ohio.

PRODUCER GAS

Analysis. Graphical Treatment of Stack Gas Analysis and of Producer Gas Analysis—II, W. Trinks. Blast Furnace & Steel Plant, vol. 10, no. 2, Feb. 1922, pp. 131–135, 8 figs. Graphical representation of producer-gas analysis. Review of graphic charts as introduced by W. Ostwald.

PULVERIZED COAL

Combustion. Combustion of Pulverized Fuel, F. P. Coffin. Combustion, vol. 6, no. 3, Mar. 1922, pp. 129–132, 1 fig. Chemistry of combustion; ash; flames; velocities of fuels; preheating air for combustion; control of furnace temperature. (Excerpt.)

Evaporative Tests. Pulverized Coal (Le combustible pulvérisé), Charles Baron. Mémoires et Compte Rendue des Travaux de la Société des Ingénieurs Civils de France, vol. 74, no. 7–8 9, July-Sept. 1921, pp. 403–411, 1 fig. Details of evaporation tests carried out at various plants to show efficiency of powdered coal burning.

PUMPING ENGINES

Vertical Triple-Expansion. The Vertical Triple-Expansion Pumping Engine, L. A. Quayle and F. H. Brown. Mech. Eng., vol. 44, no. 3, Mar. 1922, pp. 155–161 and (discussion) pp. 161 and 176, 5 figs. Study of pumping-engine installations at Cleveland, Ohio, during past 65 years. New record performance at Division Ave. pumping station.

PUMPS, CENTRIFUGAL

Sugar Industry. Centrifugal Pumps in Sugar Processes, Irwin McNiece. Sugar, vol. 24, no. 2, Feb. 1922, pp. 92–93. Discusses some salient pumping problems, and what requirements of the units must be to obtain maximum service. From Sugar Central and Planters' News.

Water Leakage. On the Leakage of Water through the Clearance Rings in a Centrifugal Pump, Otogorô Miyagi. Technology Reports of Tôhoku Imperial University, vol. 2, no. 3, 1921, pp. 1–16, 3 figs. Notes on pressure difference at clearance rings; quantity of leakage; volumetric efficiency; loss of head due to leakage. Numerical example is given.

PYROMETERS

Maintenance. Some of the Difficulties Experienced in Maintaining a Pyrometer Installation in a Works, Robert S. Whipple. Ceramic Soc. Trans., vol. 21, Part 1, Session 1921–22, pp. 1–23, 7 figs. Chief difficulties experienced with pyrometers and methods by which they can be overcome or avoided. Same article in French, pp. 24–43.

R

RADIODYNAMICS

Control of Automotive Devices. Radio Control, H. H. Germond and W. P. Flynn. Wisconsin Engr., vol. 26, no. 5, Feb. 1922, p. 87, 1 fig. Discusses development of radiodynamics and describes a radio-controlled cart.

RAILLESS TRACTION

Rail vs. Trackless Transportation Versus Rail Transportation, Karl A. Simmon. Elec. Ry. Jl., vol. 59, no. 6, Feb. 11, 1922, pp. 233–236, 2 figs. Advantages and disadvantages of trolley, auto bus, and trackless trolley. Draws definite conclusions as to field for which each type of vehicle is most suitable.

RAILS

Corrugation. Formulas for Wave Lengths of Corrugations and Axis Diameters (Formeln fur Riffellängen und Achsendurchmesser), Emil Madsen. Verkehrstechnik, vol. 38, no. 35, Dec. 15, 1921, pp. 543–546, 2 figs. Results of investigation show that a proper axle diameter is of greatest importance in overcoming corrugation, causes for which are enumerated.

Failures. French Investigation of Rail Failures Charles Fremont. Iron Age, vol. 109, no. 8, Feb. 23, 1922, pp. 523–524, 8 figs. Causes of increasing number. Effect of exfoliation. Rapid corrosion of rails. Segregation and poor-quality metal. Translated from Génie Civil, Nov. 19, 1921.

Heads, Conditions Affecting. Conditions Which Affect the Head of the Rail, James E. Howard. New York R. R. Club Official Proc., vol. 32, no. 3, Jan. 20, 1922, pp. 6611–6619 and (discussion) 6619–6625. Discusses strains in rails due to cooling; formation of cracks; rail tests; rail failures; etc.

Internal Fracture. The Presence of Internal Fractures in Steel Rails and Their Relation to the Behavior of the Material under Service Stresses, Henry S. Rawdon. Faraday Soc. Trans., vol. 17, part 1, no. 49, Dec. 1921, pp. 110–116, 7 figs. Discusses discontinuities or internal fractures in some types of steel rails and in other wrought-steel products, evidently serving as "nucleus" or starting point from which larger defects, termed transverse fissures, grow, under stress conditions to which rails are subjected in pratice.

Loads, Action of. Action of Rolling Loads on Rails (Étude de l'action des charges roulantes sur les rails), S. Timochenko. Le Génie Civil, vol. 79, no. 26, Dec. 24, 1921, pp. 555–556. Assumes the rail as a bar of infinite length on a continuous elastic base, and develops formulas.

RAILWAY CONSTRUCTION

Reinforced Concrete, Use of. On the Question of Reinforced Concrete (Holland), C. Leemans. Int. Ry. Assn. Bul., vol. 4, no. 2, Feb. 1922, pp. 347–358, 16 figs. Use of ordinary concrete and reinforced concrete on state railways of Java and Sumatra.

RAILWAY ELECTRIFICATION

Chile. Electrification of the Chilean State Railways. Ry. Rev., vol. 70, no. 6, Feb. 11, 1922, pp. 185–188, 5 figs. Application of hydroelectric power; details of electrification; direct current system considered best suited to conditions.

Direct Current. Railway Electrification with Direct Current (Jernbanernes elektrificering med likeströ m), C. Mohr. Elektroteknisk Tidsskrift, vol. 35, nos. 4, 5 and 6, Feb. 5, 15 and 25, 1922, pp. 23–26, 32–36 and 43–45, 9 figs. Notes on adoption of direct current for electrification of railway section between Kristiana and Trondhjems.

England. London, Brighton & South Coast Railway Electrification, Philip Dawson. Ry. Gaz., vol. 36, no. 6, Feb. 10, 1922, pp. 209–211, 1 fig. Report on proposed substitution of electric for steam operation of suburban, local and main-line passenger and freight services. (Abstract.)

France. The Foremost French Railway Electrification Project, G. de La Rochette. Ry. Rev., vol. 70, no. 5, Feb. 4, 1922, pp. 148–152, 6 figs. Midi Railway is developing water power for local industries and operation of 1850 miles of line. Will generate 396,000 hp. in six big hydroelectric centers.

Improvements Due to. Electrification and Its Relation to Steam Railroads, N. W. Storer. St. Louis Ry. Club Official Proc., vol. 26, no. 9, Jan. 13, 1922, pp. 188–197 and (discussion) 197–208. Discusses improvements due to electrification, and electric locomotives.

Switzerland. The Electrification of the Gotthard Line Between Lucerne and Chiasso (Die Elektrisierung der Gotthardstrecke Luzern-Chiasso der Schweizerischen Bundesbahnen), K. Sachs. Elektrotechnische Zeit., vol. 43, nos. 1, 2, 3, 4, 5 and 6, Jan. 5, 12, 19, 26, Feb. 2 and 9, 1922, pp. 1–7, 47–52, 78–85, 114–120, 143–148 and 180–186, 75 figs. Deals with power supply and distribution, power stations, feeder systems, overhead lines, and locomotives.

RAILWAY MAINTENANCE

Ditching Machines. Railway Ditching Machines and Performance Records. Eng. News-Rec., vol. 88, no. 10, Mar. 9, 1922, pp. 390–393, 5 figs. Wing-type ditchers clear track ditches and dress slopes rapidly and cheaply. Comparative costs of hand, team and machine work.

RAILWAY MANAGEMENT

Freight Loss and Damage. Prevention of Freight Loss and Damage, Joe Marshall. Can. Ry. Club Proc., vol. 21, no. 1, Jan. 1922, pp. 19–36 and (discussion) 36–40. Discusses claim prevention, the various kinds of damages for which claims are made, etc.

RAILWAY MOTOR CARS

Converted Auto Trucks. Making Motor Rail Cars from Auto Trucks, Donald A. Hampson. Ry. Rev., vol. 70, no. 6, Feb. 11, 1922, pp. 191–192, 2 figs. Describes a two-car Reo train, built by J. B. Worchester Co., Middletown, N. Y., for Alabama road, with seating capacity of 24 in each car, and operating crew of two.

Developments. Recent Development in the Railcar Field. Automotive Industries, vol. 46, no. 10, Mar. 9, 1922, pp. 556–557, 5 figs. Describes car of Indiana Truck Corp. and that of Service Motor Truck Co. Both fitted with regular and special reverse gear-sets which make possible high-speed operation in either direction, and both employ four-wheel leading trucks with live axles running in plain bearings.

Gasoline. Operating Results with Gasoline Motor Cars. Ry. Age, vol. 72, no. 9, Mar. 4, 1922, p. 516. Describes operation of Bowen motor cars by Pittsburgh and Shawmut Company to reduce cost of maintaining passenger service.

RAILWAY OPERATION

Automatic Train Control. Automatic Train Control on the Chesapeake & Ohio Ry. During the Big Snow Storm. Ry. Rev., vol. 70, no. 8, Feb. 25, 1922, pp. 257–258. Report from Calvin W. Hendrich, of Am. Train Control Co., Baltimore, of behavior of his system of automatic train control during recent heavy snow fall.

G. R. S. Company's Auto-Manual Train Control. Ry. Age, vol. 72, no. 9, Mar. 4, 1922, pp. 521–523, 6 figs. Improvements of automatic train-control system of Gen. Ry. Signal Co., Rochester, N. Y.

Train Control Test on Raritan River. Ry. Signal Engr., vol. 15, no. 2, Feb. 1922, pp. 58–60, 2 figs. Describes automatic train control of "M-V All Weather" Train Controller Co. of Newark, N. J., and tests carried out on Central of New Jersey.

Webb Automatic Train Control Tested on the Erie Ry. Signal Engr., vol. 15, no. 2, Feb. 1922, pp. 65–66, 2 figs. Describes nine tests made on Erie R. R., all of which were satisfactory.

Avoidable Waste. Avoidable Waste in Car and Locomotive Operation, William Elmer. Mech. Eng., vol. 44, no. 2, Feb. 1922, pp. 93–97, 2 figs. Outlines procedure for determining whether engines are properly loaded and used. Includes several appendices, one of which gives method of working out most economical tonnage for loading freight engines of any division, based on actual practicable performance in everyday operation. Discusses avoidable waste in operation of cars under three heads: (1) Their utilization in hands of agents, shippers and consignees; (2) handling and dispatchment in yards and on road; and (3) repair and inspection.

RAILWAY SHOPS

Can. Pac., Montreal. A Railroad Shop Organized for Efficiency. Machy. (Lond.), vol. 19, nos. 487 and 488, Jan. 26 and Feb. 2, 1922, pp. 502–504 and 535–537, 8 figs. Describes Angus shops of Can. Pacific Ry. Co., Montreal, Canada. Jan. 26: General arrangement. Feb. 2: Designs of jigs and fixtures used; outlines some methods that have made it possible to reduce costs.

Machining Operations, Cost of. What is Wrong with the Railroad Shops? Edward K. Hammond. Machy. (N. Y.), vol. 28, no. 7, Mar. 1922, pp. 557–560. Investigation into relative costs of performing machining operations in seven representative railroad shops.

RAILWAY SIGNALING

Automatic-Block. Automatic Block Signaling, J. E. Saunders. Armour Engr., vol. 13, no. 2, Jan. 1922, pp. 71–85, 8 figs. Economy of automatic signals; manual versus automatic block; train operation by signal indication; elements of automatic block signaling.

Color-Light. Color Light Signals. Ry. Engr., vol. 43, no. 505, Feb. 1922, pp. 65–66 and 74. Report of committee on Light Signals appointed by Minister of Transport. Advocates this type of signal, a color-light type with separate lenses for each color indication.

Federal Audible Signal. The Federal Signal Company's Audible Signal. Ry. Age, vol. 72, no. 9, Mar. 4, 1922, pp. 517–518, 4 figs. Describes experiments on Boston & Albany in Mass. and New York. An audible warning sounded in conjunction with visual indication given by three-position automatic semaphore.

Locking Arrangement. Locking Arrangement for Movable Point Crossing Frogs, F. Parsons. Ry. Signal Engr., vol. 15, no. 2, Feb. 1922, pp. 63–64, 4 figs. Describes system installed on Central of Argentine which insures safety with minimum apparatus. Read before Inst. Ry. Signal Engrs.

Phase Shifter for A. C. Circuits. A Phase Shifter for Adjusting A. C. Track Circuits, W. F. Price. Ry. Signal Engr., vol. 15, no. 2, Feb. 1922, pp. 61–62, 8 figs. Discusses lag of current in wet and dry weather and describes a phase shifter which works equally well on double element vane or galvanometer relays.

Three-Position, Belgium. Weissenbruch Thee-Position Signal System as Used in Belgium, T. S. Lascelles. Ry. Signal Engr., vol. 15, no. 2, Feb. 1922, pp. 55–58, 6 figs. Four indications given, clear, caution, attention or stop. Illustrations of the various positions.

RAILWAY STATIONS

Train Indicator Time-Tables. Train Indicator Time-Tables at Railway Stations. Ry. Gaz., vol. 36, no. 5, Feb. 3, 1922, pp. 177–179, 3 figs. Describes Benn & Cronin train indicator time-table.

RAILWAY TIES

Creosoting Timber Bridges and. Creosoting Timber on the Santa Fe Railway System, A. F. Robinson. West. Soc. Engrs. Jl., vol. 27, no. 3, Mar. 1922, pp. 84–90 and (discussion) pp. 90–96. Deals with creosoting timber bridges and track ties. See also Ry. Maintenance Engr., vol. 18, no. 2, Feb. 1922, pp. 44–46, 1 fig. (Abstract.)

RAILWAY TRACK

Ballast. Report of Committee 11—On Ballast. Am. Ry. Eng. Assn. Bul., vol. 23, no. 239, Sept. 1921, pp. 131–158, 6 figs. Application of ballast; ballast tools; specifications for ballast shovels.

Frogs, Reclaiming. Philadelphia & Reading Reclaims Frogs by Unique Methods. Ry. Mainetnance Engr., vol. 18, no. 1, Jan. 1922, pp. 13–14, 8 figs. Describes system which, it is claimed, is attended with very satisfactory results. Both plain and hard center equipment is repaired.

Maintenance. Track Maintenance by Contract on the Canadian Pacific Ry., H. G. Harton. Eng. News-Rec., vol. 88, no. 10, Mar. 9, 1922, pp. 399–401. Successful results of three years on 400 miles.

Plant Sidings. Trackage for Industrial Plants, Fred F. Hartford. Indus. Management, vol. 63, no. 3, Mar. 1922, pp. 151–154, 5 figs. Factors underlying their profitable installation.

Snow Fences. Snow Fence Design and Location. Elec. Traction, vol. 18, no. 2, Feb. 1922, pp. 144–146, 4 figs. Describes types successfully used by Chicago, North Shore and Milwaukee R. R., Rochester & Syracuse R. R., and Quebec Railway, Light, Heat & Power Co.

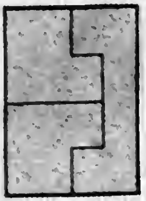
RAILWAYS

Cost of Transportation. On the Question of Net Cost; Rates (All Countries except America), Henry Gréard. Int. Ry. Assn. Bul., vol. 4, no. 2, Feb. 1922, pp. 331–345. Determination of net cost of carriage (passengers and goods), taking capital charges into consideration. Its relation to rates charged.

Reconstruction, France. Rebuilding Railway

Made in all sizes-1½" to 120" Diameter

(Larger if necessary)



The right-angled **INTERLOCK** is your safeguard

A Challenge to Your Vision

When new ideas are born, they face many tests and encounter a wall of indifference and opposition.

We are loath to abandon old ideas—right or wrong. If they are right they survive and replace worn out notions.

For nine years—

Zelnicker Ever-Tyte The Piston Ring for All Engines

has claimed attention from those who could see in today's achievements the dawn of a still greater tomorrow. EVER-TYTES' results have surpassed the expectations of critical users in all units. On their performance, they have stood unchallenged with maximum savings and greater capacity.

Now coated on the face with .003" Zinc, they seat and deliver full capacity in an incredibly short time.

Will You Investigate EVER-TYTES NOW?

Gillette Safety Razor Co.

The Ever Tight Piston Ring Co.,

St. Louis, Mo.

Gentlemen:

Replying to your letter of October 30th, we are using your Ever-Tyte Piston Rings on gas engines, and are receiving very good service.

Yours very truly,

GILLETTE SAFETY RAZOR COMPANY,

Material Division.

EVER-TYTE PISTON RING DIVISION
WALTER A. ZELNICKER SUPPLY CO.
1600 KINGSLAND AVE (WELLSTON) ST LOUIS

Structures in Northern France, M. Pellarin. Eng. News-Rec., vol. 88, no. 10, Mar. 9, 1922, pp. 397–398, 3 figs. Unique operations employed to save as much of damaged structures as possible. Work on Nord and Est railways cited. Translated from Revue Générale des Chemins de Fer.

Russia. The Railroad Transportation Situation in Soviet Russia, E. A. MacMillan. Ry. Rev., vol. 70, no. 7, Feb. 18, 1922, pp. 218–222, 1 fig. Describes deplorable condition of present rail equipment. (Abstract.) Read before Can. Ry. Club.

South America. South American Transportation Problems (Südamerikanische Verkehrsprobleme), Colin Ross. Verkehrstechnik, vol. 39, no. 4, Jan. 27, 1922, pp. 42–47, 2 figs. Review of development of South American railways; the Argentinian railways; transportation over the Andes; the railway systems of Chile and Brazil; the central trans-continental lines; the Pacific railways.

Tests Department, New Haven, R. R. The Department of Tests of the New Haven Railroad, H. P. Hass. New England R. R. Club, Jan. 10, 1922, pp. 235–248 and (discussion) 248–272. Discusses objects of the department, which are, principally, safety and economy of operation, methods used to obtain proper product being, through use of specifications and through use of tested product sheets. Details of the five divisions of department.

REFRACTORIES

American Practice. Notes on American Practice in Refractories, W. J. Rees. Ceramic Soc. Trans., vol. 21, Part 1, Session 1921–22, pp. 69–84 and (discussion) 84–88, 19 figs. Outstanding feature of American practice is well-developed organization of plant for maximum production with minimum costs.

New. The Development of a New Refractory, A. F. Greaves-Walker. Soc. of Chem. Industry Jl., vol. 41, no. 2, Jan. 31, 1922, pp. 13T–14T. Describes work undertaken by Am. Refractories Co. in conjunction with Mellon Inst. on the production of a new refractory, and laboratory tests made.

Resistance Tests. Resistance Tests on Refractory Products under Load at Different Temperatures, V. Bodin. Ceramic Soc. Trans., vol. 21, Part 1, Session 1921–22, pp. 56–65, 8 figs. Discusses investigations to find method of determining directly crushing strength at different temperatures, and their results. In French, pp. 44–55.

Thermal Conductivity. On the Determination of the Thermal Conductivity, Specific Heat, Density and Thermal Expansion of Different Rocks and Refractory Materials, Yoshiaki Tadokoro. Tohoku Imperial University Sci. Reports, vol. 10, no. 5, Dec. 1921, pp. 339–410, 42 figs. partly on supp. plates. Account of investigation begun four years ago in research laboratory of Imperial Steel Works, Yawata.

REFRIGERATING PLANTS

Condenser Cooling-Water Diagram. Cooling Water for Ammonia Condenser, Alex H. Luedicke. Power, vol. 55, no. 8, Feb. 21, 1922, p. 302, 1 fig. Explains easy way to find amount of water required.

Corrosion in Systems. Control of Corrosion in Refrigerating Systems, F. N. Speller. A.S.R.E. Jl., vol. 8, no. 3, Nov. 1921, pp. 216–221 and (discussion) 221–224. Reviews what has been done and discusses possible application of these principles. Methods of protection are divided into two classes, viz.: by rendering water slightly alkaline, usually done by use of lime; and by eliminating free oxygen from solution.

REFRIGERATION

Brine Freezing of Fish. Brine Freezing of Fish, Harden F. Taylor. Refrig. World, vol. 57, no. 1, Jan. 1922, pp. 21–24. Refrigeration promises only solution of problem of distributing fish from sea to distant consumers in first-class condition. Describes brine freezing process. Brine-frozen versus air-frozen fish.

RESEARCH

Mechanical Engineering Advisory Committee. Mechanical Engineering Advisory Committee for Division of Engineering, Alfred D. Flinn. Mech. Eng., vol. 44, no. 2, Feb. 1922, pp. 115–116. Describes contemplated program of committee formed within organization of Am.Soc. of Mech.Engrs.

Problems. Research Problems Discussed. Mech. Eng., vol. 44, no. 2, Feb. 1922, pp. 117–118. Discussion of papers by F. A. Wardenburg and A. D. Flinn. Report of A.S.M.E. work in lubrication, by Albert Kingsbury. Progress in steam-table research described.

ROLLING MILLS

Engines, Combination Gas and Steam. Development of Rolling Mill Engines, F. J. Denk. Blast Furnace & Steel Plant, vol. 10, no. 2, Feb. 1922, pp. 153–154. Advantages of combination of gas engine with steam engine.

Sheet Mills. Apollo Steel Company Enlarge Plant by the Addition of a New Sheet Mill Unit. Blast Furnace & Steel Plant, vol. 10, no. 2, Feb. 1922, pp. 126–130, 9 figs. Describes general layout, buildings, and equipment, including modern improvements in sheet-mill construction.

Extends Facilities for Sheetmaking. Iron Trade Rev., vol. 70, no. 8, Feb. 23, 1922, pp. 532–537, 10 figs. Otis Steel Co. completes eight-mill plant at its Riverside works, Cleveland. Substantial construction of buildings, liberal floor areas for all operations and flexible crane system are outstanding features.

Otis Steel Company Completes the Erection of a Modern Sheet Mill Department, Donald N. Watkins. Blast Furnace & Steel Plant, vol. 10, no. 2, Feb. 1922, pp. 118–122, 7 figs. Located at Riverside plant in Cleveland. Most important installations include extra heavy mills, electric drives, powdered coal fuel, continuous pair furnaces, electric furnace chargers, Baird water-cooled floors, etc.

Tables. Roller Bearings Mill Tables, J. M. Kelly. Blast Furnace & Steel Plant, vol. 10, no. 2, Feb. 1922, pp. 139–141, 2 figs. Describes new rolling mill tables in which were installed flexible roller bearings.

RUBBER

Thermal Insulation. Thermal Insulation of Rubber. Rubber Age, vol. 2, no. 12, Feb. 1922, p. 590. Discusses report by Food Investigation Board of experiments made with onazote.

Vulcanized. Determination of True Free Sulfur and True Coefficient of Vulcanization in Vulcanized Rubber, W. J. Kelly. Jl. Indus. & Eng. Chem., vol. 14, no. 3, Mar. 1922, pp. 196–197. Describes methods of analysis by means of which a more complete study of distribution of sulphur between the various ingredients of rubber compound can be made.

S

SCIENTIFIC MANAGEMENT

See INDUSTRIAL MANAGEMENT.

SHAFTS

Torsional Vibrations. Torsional Vibrations of Shafts (Verdrehungsschwingungen von Wellen), O. Föppl. Schweizerische Bauzeitung, vol. 79, no. 5, Feb. 4, 1922, pp. 56–59, 11 figs. Demonstrates practical applicability of theoretical determination of coefficients of natural vibration of shafts with rotating masses.

SHEARS

Pressure Required for Shearing. Formulas for Pressure Required for Shearing Metal, D. C. Oviatt. Machy. (N. Y.), vol. 28, no. 7, Mar. 1922, p. 528, 1 fig. Presents formulas for shear calculation and explains application.

SHERARDIZING

Experiments. Experiments with Sherardizing, Leon McCulloch. Min. & Metallurgy, no. 182, Feb. 1922, p. 63. Study of effect of iron in zinc dust on sherardizing process and on resulting coatings, giving evidence that no part of a sherardized coating can contain less than 6 per cent iron. (Abstract.) See also Am. Inst. Min. & Met. Engrs. Trans., no. 1131–N, Feb. 1922, 4 pp. (complete paper).

SINE BARS

Uses. The Use of the Sine Bar. Machy. (Lond.), vol. 19, no. 488, Feb. 2, 1922, pp. 529–531, 6 figs. Gives some examples of wide range of angle work covered by it. Is more adaptable than the protractor.

SPRINGS

Handling and Heat-Treating. Methods of Handling and Heat-Treating Springs. Can. Machy., vol. 27, no. 8, Feb. 23, 1922, pp. 21–25, 23 figs. Principles governing uniform heating and cooling; type and arrangement of equipment; stationary and continuous furnaces; utilizing heat in waste gases.

Impact Absorption. Graphic Representation of Absorption of Impact by Springs, Leslie H. Mann. Machy. (N. Y.), vol. 28, no. 7, Mar. 1922, pp. 554–555, 2 figs. Determination of energy absorbed by spring under load based upon assumption that body producing deflection of spring is moving with its center of gravity in line with axis of spring, or in line with point that will cause spring to act most efficiently.

STANDARDIZATION

Advantages. Significance of Standardization to American Industry and the Federal Government, A. A. Stevenson. Mech. Eng., vol. 44, no. 3, Mar. 1922, pp. 185–186 and 203. Advantages of standardization to all, including Government as largest consumer. How Government should coöperate with industry. What is being done by Am. Eng. Standards Committee.

Waste Elimination through. Waste Elimination Through Standardization, H. Campbell and Alex Tauh. Am. Mach., vol. 56, no. 10, Mar. 9, 1922, pp. 363–364. Reducing manufacturing costs. How standardization benefits both manufacturer and consumer. Introduction of universal numbering system. Multiplying service by six.

STEAM

Ruths Storage System. The Ruths Steam Accumulators (L'accumulatore di vapore Ruths), E. C. Constam-Gull. Industria, vol. 35, no. 24, Dec. 31, 1921, pp. 521–527, 17 figs. Various examples of application of this system of equalizing pressure loads; savings effected in fuel.

The Ruths Steam Storage System (Der Ruthssche Dampfspeicher), G. Schulz. Stahl u. Eisen, vol. 42, no. 5, Feb. 2, 1922, pp. 165–171. Writer points out favorable influence on boiler fire effected by a constantly uniform steam consumption in boiler house, which has been verified by tests conducted by Prof. Jossé, Berlin. It is claimed that this uniform steam consumption can, in many cases, be obtained by use of a new steam accumulator which is described.

STEAM ENGINES

Steam Consumption of Reciprocating. The Coefficients of Steam Consumption of Reciprocating Steam Engines (Die Verbrauchzahlen der Kolbendampfmaschinen und ihre Beurteilung), R. Doerfel. Zeit. des Vereines deutscher Ingenieure, vol. 66, nos. 4 and 6, Jan. 28 and Feb. 11, 1922, pp. 84–87 and 133–136, 10 figs. Revisal of rules for efficiency tests. Determination of tolerances. Results of tests on state of resistance. Thermal equivalent according to the law of 1899 and method subsequently in use of determining steam consumption reckoned from zero deg. cent. feedwater temperature or with arbitrary deductions. The Clausius-Rankine comparative method and difficulty of evaluation of waste heat in feedwater and water of condensation of cylinder walls, cover and receiver.

Torsiograph, Measurements with. The Torsiograph and Its Use in Steam-Engine Operation (Ueber den Torsiographen und seine Anwendung im Dampfmaschinenbetriebe), Jos. Geiger. Elektrotechnik u. Maschinenbau, vol. 40, no. 4, Jan. 22, 1922, pp. 40–42, 4 figs. Describes instrument for measurement of deviation of angle, coefficient of cyclic variation and the varying torsional stresses in transmission gears and crankshafts.

STEAM GENERATORS

Electrically Operated. Generation of Steam by Electricity, E. T. Kaelin. Eng. Jl. (Eng. Inst. Can.), vol. 5, no. 3, Mar. 1922, pp. 127–133, 7 figs. Field of use for electric-steam generator, its advantages to consumer from load-factor point of view and to electric supply company as outlet for surplus power. Discusses types of electric-steam generators with particular reference to water-resistance type.

STEAM PIPE

Diameter. The Most Economical Pipe Diameter for Steam-Power Piping (Der billigste Rohrdurchmesser für Kraftdampfleitungen), O. Denecke. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, nos. 49, 50, 51 and 52, Dec. 9, 16, 23 and 30, 1922, pp. 394–396, 405–408, 418–421 and 427–431, 4 figs. Calculation of diameter taking only pipe friction into consideration, and taking separate resistances into consideration. Numerical examples of high-pressure saturated-steam turbines.

STEAM POWER PLANTS

Oil-Burning. Operation of Oil-Burning Steam Plants, C. H. Delany. Iron Age, vol. 109, no. 8, Feb. 23, 1922, pp. 525–527, 4 figs. Discussion of plant characteristic diagram, with particulars regarding its use in establishment of a standard of performance and in increasing plant efficiency. (Abstract.) Paper presented at joint meeting of Am.Soc.Mech.Engrs. and Am.Inst.Elec.Engrs.

STEAM TURBINES

Efficiency Tests of 60,000-Kw. Efficiency Tests of a 60,000-Kw. Turbine, Herbert B. Reynolds and Walter F. Hovey. Power, vol. 55, no. 11, Mar. 14, 1922, pp. 411–413, 4 figs. Results of tests on turbine installed in power station of Interborough Rapid Transit Co. (Abstract.) Paper to be read before Am.Soc.Mech.Engrs.

STEEL

Alloy. See ALLOY STEELS.

Basset Direct-Production Process. Direct Production of Steel (La production directe de l'acier), E.-H. Weiss. Nature, no. 2491, Dec. 31, 1921, pp. 423–427, 5 figs. Describes Basset process as applied at Dennemont works, of producing steel direct from ore.

Cracking. Intercrystalline Cracking of Mild Steel in Salt Solutions, J. A. Jones. Faraday Soc. Trans., vol. 17, part 1, no. 49, Dec. 1921, pp. 102–109, 9 figs. Describes action of various solutions in producing cracking of steel in state of stress.

Failure on Hardening. The Mechanism of the Failure of Steel upon and after Hardening. G. W. Green. Faraday Soc. Trans., vol. 17, part 1, no. 49, Dec. 1921, pp. 139–145, 7 figs. Outlines causes of stressing and subsequent failure.

Fatigue Tests. Endurance of Steel Under Repeated Stresses, D. J. McAdam, Jr. Chem. & Met. Eng., vol. 25, no. 24, Dec. 14, 1921, pp. 1081–1087, 22 figs. Fatigue tests on many commercial and alloy steels develop no evidence of "endurance limit;" ultimate tensile strength closely related to endurance stress at 1,000,000,000 cycles; special White-Souther machine and semi-logarithmic graphs used.

Identification and Storage. A New Idea in Steel Identification and Storage. Ry. & Locomotive Eng., vol. 35, no. 2, Feb. 1922, pp. 44–45, 2 figs. Describes method of marking steel bars for identification, and also designing and constructing suitable steel storage racks, employed by Gould & Eberhardt, Newark, N. J.

Literature, 1921. Review of Iron and Steel Literature for 1921, E. H. McClelland. Blast Furnace & Steel Plant, vol. 10, no. 1, Jan. 1922, pp. 4–8. Classified list of the more important books, serials and trade publications during year, with a few of earlier date, not previously announced. Also in Forging and Heat Treating, vol. 8, no. 1, Jan. 1922, pp. 4–8.

Phosphorus, Influence of. Influence of Phosphorus upon the Microstructure and Hardness of Low-Carbon, Open-Hearth Steels, Edward C. Groesbeck. U. S. Bur. of Standards Technologic Papers, no. 203, Nov. 21, 1921, pp. 1–33, 15 figs. Two series of specimens, one of basic and the other of acid open-hearth steel, with phosphorus content in each series varied in four or five steps within limits 0.008 to 0.115 per cent, which mark the ordinary limits of phosphorus content in plain carbon steel, were employed in study of relationship between phosphorus content and microstructure and hardness resulting from series of different heat treatments tried.

Properties in Hardening Range. Properties of Some Steels in the Hardening Range, W. R. Chapin. Am. Soc. for Steel Treating Trans., vol. 2, no. 6, Mar. 1922, pp. 507–514 and (discussion by Zay Jeffries) pp. 514–515, 4 figs. Report applies only to steels which, when properly quenched, harden throughout mass, and are martensitic when so hardened.

ACORN
BRAND

A babbitt that will not break

Recent analyses of bearing failures by one of the principal railroads and by one of the leading manufacturers of automobiles showed that more than eighty per cent of these failures were due to breakage of the babbitt lining.

Cadman's ACORN Babbitt is the only metal which is guaranteed to eliminate this trouble. The photographs reproduced above illustrate its remarkable ductility. A load of 67400 pounds applied to a cylinder 1 inch in area and 1½ inches high, equivalent to a pressure of more than 33 tons per square inch, failed to fracture the sample. A cast rod bent double shows no sign of breakage.

This unique ductility is combined with superior bearing properties in every other respect.

A sample of ACORN Babbitt, proving our ability to guarantee that it will not fracture under any conditions, will gladly be mailed upon request.

(Clip the coupon or simply enclose your card in an envelope)

Wire, Low-Carbon Steel. Ghost Lines and Grain Elongations in Hot Rolled and Cold Drawn Low Carbon Steel Wire, N. B. Hoffman. Am. Soc. for Steel Treating Trans., vol. 2, no. 6, Mar. 1922, pp. 516–523 and (discussion) pp. 523–525, 26 figs. Shows relation existing between ghost lines, bands, and elongated grain structures as found in low-carbon steel wire.

STEEL CASTINGS

Heat Treatment. The Heat Treatment of Steel Castings, Walter H. White. Am. Soc. for Steel Treating Trans., vol. 2, no. 5, Feb. 1922, pp. 437–440. Suggestions for obtaining good results.

STEEL, HEAT TREATMENT OF

Alloy Carbonizing Boxes. Do Alloy Carbonizing Boxes Pay? C. M. Campbell. Am. Soc. for Steel Treating Trans., vol. 2, no. 6, Mar. 1922, pp. 495–499. Considers factors governing life and performance of carbonizing boxes, and reasons why they should not be placed on supply account instead of becoming part of equipment.

Brinell Hardness, Calculating. New Development on the Influence of Mass in Heat Treatment, E. J. Janitzky. Am. Soc. for Steel Treating Trans., vol. 2, no. 5, Feb. 1922, pp. 377–383, 2 figs. Also Iron Age, vol. 109, no. 10, Mar. 9, 1922, pp. 658–659, 2 figs. Suggested formula for calculating Brinell hardness from given data. Applicable to alloy and carbon steels. Paper presented at N. Y. Section of Am. Soc. for Steel Treating.

Carbon Steel. Effect of Heat Treatment on the Mechanical Properties of 1 Per Cent Carbon Steel, H. J. French and W. George Johnson. U. S. Bur. of Standards Technologic Papers, no. 206, Dec. 27, 1921, pp. 93–121, 16 figs. Study of effects of varying time-temperature relations in heat treatment on tensile and impact properties, hardness, and structure of 1 per cent carbon steel, including (a) effect of temperature variations in hardening (b) time at hardening temperatures both above A_{cm} and between the Ac_1 and A_{cm} transformations, (c) effects of tempering steel hardened in different ways and effects of "soaking" just under lower critical range, (d) comparison of oil and water hardening for production of definite strengths.

Effect of Heat Treatment on the Mechanical Properties of One Per Cent Carbon Steel, H. J. French and W. George Johnson. Am. Soc. for Steel Treating Trans., vol. 2, no. 6, Mar. 1922, pp. 467–494, 16 figs. Results of tests show that most suitable oil or water quenching temperature for steel which is subsequently to be tempered at relatively high temperatures is slightly above end of Ac_1 transformation.

Cold-Headed Bolts. Cold-Headed Bolts—Their Metallography and Heat Treatment, W. E. Hillman. Am. Soc. for Steel Treating Trans., vol. 2, no. 5, Feb. 1922, pp. 369–376, 20 figs.; also Iron Trade Rev., vol. 70, no. 8, Feb. 23, 1922, pp. 538–541, 18 figs. Various degrees of distortion may be found in same bolt; however, annealing at 1150 deg. Fahr. will remove weakening effect of cold work. Annealing above critical range is preferable.

Fixtures for. Special Fixtures for Heat Treating, E. H. Tingley. Forging & Heat Treating, vol. 8, no. 2, Feb. 1922, pp. 96–99, 7 figs. Describes a number of appliances for heating and quenching small parts as developed from suggestions made by workmen of Delco-Light Co. heat-treating department.

Structural Changes due to Heating Medium. Influence of the Heating Medium on the Structural Changes in Steel, A. E. Bellis. Am. Soc. for Steel Treating Trans., vol. 2, no. 5, Feb. 1922, pp. 398–401 and (discussion) pp. 401–402. Analysis of structural changes as they are influenced by heating and cooling medium.

STEEL PLANTS

Pressed Steel. Description of a Pressed Steel Plant. Blast Furnace & Steel Plant, vol. 10, no. 2, Feb. 1922, pp. 144–147, 4 figs. Brief history of reorganization of Sharon Pressed Steel Co., Sharon, Pa., equipped to manufacture and assemble heavy pressed-steel products. Routing and handling.

STOKERS

Motion Pictures of Operation. Motion Pictures of a Stoker Furnace in Operation, R. Sanford Riley. Mech. Eng., vol. 44, no. 2, Feb. 1922, pp. 103–104, 4 figs. Describes invention of F. H. Daniels and pictures taken at plant of Bird & Son, Inc., East Walpole, Mass., showing operation of a 9-retort extra long Riley underfeed stoker.

STREET RAILWAYS

Cars, One-Man. One-Man Car Operation with Double-Truck Cars, H. S. Sweet. Elec. Ry. Jl., vol. 59, no. 4, Jan. 28, 1922, pp. 156–158, 9 figs. Describes new one-man car in Utica equipped with turnstiles to admit passengers who pay as they leave. (Abstract.) Paper read before N. Y. Elec. Ry. Assn.

Two New Types of Safety Cars for Chicago, Charles Gordon. Elec. Ry. Jl., vol. 59, no. 2, Jan. 14, 1922, pp. 65–71, 14 figs. Describes single-truck and double-truck one-man safety cars, both arranged for double-end operation with separate entrance and exit passageways.

STRESSES

Flat Cylinder Heads. Stresses and Deformation in Flat Circular Cylinder Heads, Gilbert Dudley Fish. Mech. Eng., vol. 44, no. 3, Mar. 1922, pp. 165–169 and (discussion) p. 170, 12 figs. Analysis covering homogeneous elastic disks, where form and loading are symmetrical with respect to all diameters, where loading is combination of fluid pressures and of forces acting normally on concentric circles, where thickness is uniform, and where all strains are within limits of true elasticity. Formulas applicable to all cases considered are developed, and equations are given for constants of integration involved in mathematical analysis.

Thermal. The Thermal Stresses in Spherical Shells Concentrically Heated, Charles H. Lees. Roy. Soc. Proc., vol. 100, no. A 705, Jan. 2, 1922, pp. 379–394, 7 figs. Discusses stresses set up in materials by difference in temperature and its application to blast furnaces and others.

STRUCTURAL STEEL

Tensile Properties. Tensile Properties of Some Structural Alloy Steels at High Temperatures, H. J. French. Am. Soc. for Steel Treating Trans., vol. 2, no. 5, Feb. 1922, pp. 409–422, 8 figs. Account of tests conducted by Bur. of Standards to determine tensile properties of a number of structural alloy steels throughout temperature range of 20 to 550 deg. cent.

SWAGING

Hot. Hot Swaging, Fred R. Daniels. Machy. (N. Y.), vol. 28, no. 7, Mar. 1922, pp. 521–526, 10 figs. Describes swaging operations, based on practice and recommendations of the Langelier Mfg. Co., Providence, R. I.

T

TEMPERATURE CONTROL

Automatic Valve. Temperature Regulation by Automatic Valve, G. A. Wegner. A.S.R.E. Jl., vol. 8, no. 3, Nov. 1921, pp. 203–210, 6 figs. Discusses control of a valve through which vapor pressure is made controlling factor, the object being to assist man in charge in his task and to make desired results more certain.

TERMINALS, LOCOMOTIVES

Georgia. An Engine Terminal for Economical Operation, G. W. Tutan. Ry. Age, vol. 72, no. 8, Feb. 25, 1922, pp. 463–467, 7 figs. Describes combined roundhouse and shops of Central of Georgia railroad, including design of enginehouse structure and shop equipment.

TERMINALS, RAILWAY

Freight. Katy Builds Freighthouse of Fireproof Construction. Ry. Age, vol. 72, no. 10, Mar. 11, 1922, pp. 559–561, 7 figs. Describes new inbound terminal of Missouri, Kansas & Texas, at Dallas, Texas.

TEXTILE INDUSTRY

Science in. Science in the Textile Industry. Mech. Eng., vol. 44, no. 3, Mar. 1922, pp. 181–184, 1 fig. Two papers presented before Textile Division of A.S.M.E.: Hidden Wastes in Textile Plants, Thayer P. Gates; and Economy in Textile Drying, B. R. Andrews. Discussion.

TIDAL POWER

Utilization. Using Sea Power (Utilisons la "Houille Bleue"), H. Lémonon. La Nature, nos. 2482 and 2484, Oct. 29 and Nov. 12, 1921, pp. 278–283 and 310–316, 19 figs. Oct. 29: Describes systems of tidal power production by Reynolds, Tommasi, Legrand, Praceiq, etc. Nov. 12: Describes systems depending on use of turbines and hydraulic accumulators.

TIME STUDY

Bedaux Human Power Measurement. The Bedaux Principle of Human Power Measurement, L. C. Morrow. Am. Mach., vol. 56, no. 7, Feb. 16, 1922, pp. 241–245, 2 figs. Describes system practiced by Chas. E. Bedaux Co., Cleveland, Ohio. Application to compensation of labor. Isolation from methods, equipment and piece rates. Simplicity of records.

Motion Study and. Time and Motion Study, Eric Farmer. Eng. & Indus. Management, vol. 7, nos. 3, 4, 5, 8, Jan. 19, 26, Feb. 2, 23, 1922, pp. 70–75, 95–98, 136–139, 221–223. Jan. 19: Review of past works by Taylor and Gilbreth. Jan. 26: New point of view in undertaking time and motion study; reducing unproductive labor. Feb. 2: Correct definition of motion study. Feb. 23: Time study.

TRACTORS

Caterpillar. A New Caterpillar Development, F. Rowlinson. Sci. Am., vol. 126, no. 3, Mar. 1922, pp. 194–195, 8 figs. British efforts to save power and increase speed by means of a track that will yield to local obstacles. Describes new type of caterpillar suspension and its application.

Four-Wheel Drive. A Four-Wheel Drive Tractor from the Pacific Coast. Automotive Industries, vol. 46, no. 10, Mar. 9, 1922, pp. 554–555, 4 figs. Describes the Wizard 4-Pull tractor which transmits power to all four wheels by roller chains and steers by disconnecting power from wheels on one side.

Road-Rail Trucks and. The Stronach Dutton System of Road Rail Traction. Roy. Engrs. Jl., vol. 35, no. 2, Feb. 1922, pp. 93–96, 2 figs. on supp. plates. Principle adopted is to support front axle of a short-wheel base tractor by a four-wheeled bogie running on a Decauville line A drawbar is carried from bogie pivot to back of tractor for attachment of such trucks as can be hauled. Most recent pattern of tractor hauling train and converting from road to rail or rail to road traction.

Samson. Cooling Capacity Increased in Samson Tractor, P. M. Heldt. Automotive Industries, vol. 46, no. 9, Mar. 2, 1922, pp. 502–505, 4 figs. Technical description. Improvements in lubricating and cooling systems; enlarging of radiator and fan; etc.

Types. Tractor Show Marked by New Designs, P. M. Heldt. Automotive Industries, vol. 46, no. 8, Feb. 23, 1922, pp. 451–457, 8 figs. Creeper tractor construction; road building and maintenance tractors; corn-belt and grain-belt tractor requirements contrasted; new machines and parts described.

TRANSPORTATION

Highway. Highway Transportation. Am. Soc. Civ. Engrs. Proc., vol. 48, no. 2, Feb. 1922, pp. 318–358. Symposium containing following papers: Highway Transportation, Thomas H. MacDonald. Inspection of Highway Construction, William G. B. Thompson. Financing and Bonding Highways, John N. Cole. Highway Bonding from the Viewpoint of the Surety Company, E. A. St. John. Financing and Bonding Highway Work, Edward C. Lunt. The Motor Vehicle in Highway Financing, Harry Meixell. The Motor Truck as an Asset to Railroad Operation, R. S. Parsons. Motor Vehicle Control, G. Wythe Munford. Discussion, W. K. Hatt.

The Muscle Shoals Plant and the Nitrogen Supply[1]

A Résumé of the Development of the Nitrate Industry in the United States and a Discussion of Its Present Requirements

By J. K. CLEMENT,[2] WASHINGTON, D. C.

This paper opens with an outline of the essential uses of nitrogen in this country and goes on to cover briefly the four forms in which nitrogen was obtainable before the processes for taking it from the atmosphere were developed.

The fixation of atmosphere nitrogen is taken up, the chief features of the three best-known methods being touched on.

Development of the industry in the United States leads to a discussion of the Government Nitrate Plant No. 2 usually spoken of as Muscle Shoals. The general conditions of this plant are outlined, including its power and raw-material requirements and the convenience with which these requirements can be supplied.

The various chemical processes are explained in some detail and finally some charts and a table give interesting side lights on the nitrogen situation in this country and abroad.

THE enormous consumption of nitrogen in the production of ammunition during the war emphasized its importance in the manufacture of military explosives. Nitrogen is an essential constituent of practically all explosives, both military and those used in blasting, mining and other industrial purposes.

Quite recently the publicity concerning the Government's projects at Muscle Shoals has recalled attention to the importance of nitrogen in agriculture and industry.

Nitrogen is essential to all vegetable and animal life and is required in a number of important industries; for example, the dye and drug industry, the refrigeration industry, the manufacture of artificial leather, photographic films, acids and chemicals. Of the three important elements of commercial fertilizers, nitrogen, potash and phosphorus, nitrogen is probably the most important.

SOURCES OF NITROGEN

Nitrogen is usually obtained in one of the following forms: proteins, ammonia, nitrates and cyanides.

The nitrogen contained in plants and animals is usually in the form of proteins and is known as organic nitrogen. A very considerable part of the nitrogen used in agriculture is organic nitrogen and is obtained from manure, cottonseed meal, dried blood, and tankage and fish scrap. Ammonia, nitrate and cyanide nitrogen are referred to as inorganic nitrogen. Until a few years ago the inorganic nitrogen supply of the world was obtained from the beds of sodium nitrate of Chile and from coal. With the exception of a small quantity of potassium nitrate produced in India, all of the "nitrate" nitrogen of the world came from Chile and the world was dependent on this source for its nitrogen for the production of explosives, nitric acid, and for use in certain important industries.

Ammonia and cyanides are obtained as by-products in the destructive distillation of coal in gas works and by-product coke ovens and in the distillation of shales.

FIXATION OF ATMOSPHERIC NITROGEN

Four-fifths of the air is nitrogen. The nitrogen of the air is, however, extremely inert, and this tremendous source of supply was therefore until within the past twenty years not available for use by man.

There are now three processes for the fixation of atmospheric nitrogen that are commercially successful:

a Arc process,
b Cyanamide process,
c Synthetic or Haber process.

Arc Process. The arc process was the first process successfully developed on a commercial scale. At the high temperature of the electric arc the oxygen and the nitrogen of the air combine to form nitric oxide. On cooling, the nitric oxide is further oxidized to nitrogen dioxide and absorbed in water to form nitric acid or acted upon by lime to form calcium nitrate. The arc process is the only fixation process that produces nitric acid directly. Its heavy power requirements, 8.41 kw-years per metric ton of nitrogen fixed, limit its use to localities where power is abundant and cheap. It has been developed chiefly in Norway.

Cyanamide Process. The cyanamide process is based on the fact that calcium carbide heated to about 1000 deg. cent. combines with nitrogen gas to form calcium cyanamide. Commercial cyanamide or lime nitrogen contains about 20 per cent nitrogen. It may be used directly as a fertilizer or treated with steam under pressure to form ammonia. The cyanamide process requires a large amount of power, 1.97 to 2.30 kw-years per metric ton of nitrogen. It was established in Italy in 1906 and later in Germany, Norway, Sweden, Canada, Austria-Hungary, France, Japan and Switzerland.

Haber Process. The Haber process for the synthesis of ammonia was established in Germany in 1913. Prior to the end of the world war it had not been successfully operated in any other country. A mixture of nitrogen and hydrogen gas, under a pressure of from 100 to 200 atmospheres, is passed over a suitable catalyzer heated to 550 deg. cent. A small percentage of the gases is converted into ammonia which is removed from the system, the remaining nitrogen and hydrogen being returned to the catalyzer. The power requirements are small, 0.42 kw-year per metric ton of nitrogen fixed.

NITROGEN-FIXATION PLANTS IN THE UNITED STATES

The desirability of the United States becoming self-sustaining as regards fixed nitrogen was recognized prior to our entry into the war, Congress having appropriated $20,000,000 for the investigation of nitrogen fixation and for the construction of nitrate plants in 1916. Shortly after the declaration of war the decision was made to erect a plant of small capacity, 10,000 tons of ammonia per year, using a modified form of the Haber process. Construction of this plant, United States Nitrate Plant No. 1, began in October, 1917.

The heavy losses to shipping caused by the German submarines in 1917 and 1918 threatened to reduce the tonnage available for the transportation of nitrate from Chile, and made it unsafe for the United States to depend on imported nitrates. To meet this condition a contract for the erection of United States Nitrate Plant No. 2 was made in November, 1917. This plant was to have a capacity of 110,000 tons of ammonium nitrate per year, and was to use the cyanamide process. The important consideration in the selection of the cyanamide process was its dependability. A plant using this process had been in operation for

Paper presented at the Spring Meeting, Atlanta, Ga., May 8 to 11, 1922, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Slightly abridged. All papers are subject to revision.

several years at Niagara Falls, Canada, and the services of the members of its operating organization were available for the design and operation of the Muscle Shoals plant. Later the program was increased to include United States Nitrate Plants Nos. 3 and 4 at Toledo and Cincinnati, Ohio, these plants to have a capacity of 55,000 tons of ammonium nitrate each.

The last two plants were not completed. Plant No. 1 was operated experimentally for several months, but not successfully. Plant No. 2 began operations about two weeks before the armistice was signed and was continued in operation long enough to demonstrate its ability to operate satisfactorily.

United States Nitrate Plant No. 2

United States Nitrate Plant No. 2 is located in northwestern Alabama, on the south side of the Tennessee River, about one mile below the Muscle Shoals. It is the largest cyanamide plant in the world, having a capacity of 220,000 tons of cyanamide or 110,000 tons of ammonium nitrate per year.

Construction of the plant began in January, 1918, and operation in October, 1918. The total cost including the 60,000-kw. steam power plant at Muscle Shoals, but not including the 30,000-kw. steam power plant on the Warrior River, the Warrior-Muscle Shoals transmission line and the Waco limestone quarry, was approximately $70,000,000.

The principal raw materials required, other than the nitrogen of the air, are limestone and coke. The daily consumption of these materials when operating at full capacity is 1200 tons of limestone and 300 tons of coke. An ample supply of limestone of pure quality is located about 30 miles south of Muscle Shoals. Coke can be procured at Birmingham.

Fig. 1 General View of Carbide Furnaces Charging Floor

When operating at full capacity the plant requires approximately 85,000 kw. This power will eventually be available at Wilson Dam which is located within a mile of the nitrate plant. To furnish the power during the war and prior to the completion of the hydroelectric development on the Tennessee River, two steam power plants were erected: one at Muscle Shoals, and one at Gorgas on the Warrior River. The plant at Gorgas, known as the Warrior extension power plant, was built as an extension to the existing plant of the Alabama Power Company. The generating unit is a 30,000-kw. General Electric turbo-generator. The Muscle Shoals plant contains a 60,000-kw. Westinghouse turbo-generator consisting of one high-pressure and two low-pressure turbines each connected to a 20,000-kw. generator.

The limestone is burned in seven rotary kilns—one of which is a spare unit—each having a capacity of 200 tons of stone a day. The coke is crushed and dried and the lime and coke are mixed in suitable proportions for charging into the carbide furnaces.

The carbide furnaces are twelve in number—ten being required for full-capacity operation. Each furnace has a rated capacity of 50 tons of 80 per cent calcium carbide per day. The power consumption of one furnace is 6000 kw. The current is 3-phase, 60 cycles, and enters the furnace from the top, through carbon electrodes.

At the temperature of the electric arc, the lime and coke react to form carbide in accordance with the equation:

$$3C + CaO = CaC_2 + CO$$

The process is continuous, the molten carbide being tapped from the surface at intervals of about forty minutes. The carbon monoxide gas burns on contact with the air to carbon dioxide which escapes into the atmosphere. Fig. 1 gives a view of the furnaces.

The carbide is allowed to cool and is then ground to a fine powder. From the mill it is conveyed to the lime-nitrogen or cyanamide building where the fixation of nitrogen takes place. At a temperature of about 1000 deg. cent. calcium carbide and nitrogen react in accordance with the equation:

$$CaC_2 + N_2 = CaCN_2 + C$$

For this reaction a pure quality of nitrogen is desired. The nitrogen is separated from the oxygen of the air by the Claude process. The nitrogen or liquid-air building contains 30 Claude columns, each having a capacity of 500 cu. m. of nitrogen an hour.

The electric ovens in which the fixation of nitrogen takes place consist of vertical cylinders about 30 in. inside diameter and 5 ft. high. The heating unit is a carbon pencil located in the center of the oven. There are 1536 of these ovens. The weight of a charge of carbide is about 1600 lb. Nitrogen gas enters at the bottom of the oven. After about four hours the electric current is turned off and the reaction, being exothermic, proceeds without further external heating. The process requires about forty hours for completion. The product is removed from the furnace in the form of a cylindrical pig of cyanamide or lime nitrogen. After cooling, the pigs are crushed and ground to a fine powder. In this condition the lime nitrogen contains about one per cent of calcium carbide which is removed by spraying with water, the water reacting with the carbide to form acetylene gas which escapes. Fig. 2 illustrates these ovens.

Fig. 2 Lime-Nitrogen Ovens

Calcium cyanamide reacts with steam under high pressure to form ammonia. The reaction is as follows:

$$CaCN_2 + 3H_2O = 2NH_3 + CaCO_3$$

This reaction takes place in large heavily walled steel autoclaves. The process is intermittent and requires from six to eight hours. The ammonia gas passes out at the top of the autoclave and carries with it a large amount of steam. Most of the steam is removed from the gas by condensation. The calcium carbonate is discharged in the form of a sludge and is a waste product. The plant has a capacity of 150 tons of ammonia per day.

The production of nitric acid from ammonia had never been carried out on a commercial scale prior to the world war, although the Ostwald process for the oxidation of ammonia to nitric oxide had been tried out on a small scale. If a mixture of ammonia and air is heated to a temperature of, say, 1000 deg. cent. under ordinary conditions, the reaction products obtained are nitrogen and water vapor. Ostwald found that by passing the gas over a suitable catalyzer, such as a fine platinum gauze, heated to a bright red heat, most of the nitrogen in the ammonia may be oxidized to nitric oxide:

$$2NH_3 + 2^1/_2O_2 = 2NO + 3H_2O$$

On cooling, the nitric oxide combines with more oxygen to form

nitrogen dioxide, which is then absorbed in water to form nitric acid.

In the Muscle Shoals plant the oxidation takes place in aluminum boxes or converters in the bottom of which the electrically heated platinum gauze is held in a horizontal position (See Fig. 3). The mixture of ammonia and air is passed downward over the gauze and the products of the reaction are carried to coolers and then to the nitric acid absorption towers. The capacity of the plant is about 450 tons of 50 per cent acid per day.

Ammonia and nitric acid react readily to form ammonium nitrate in accordance with the equation:

$$NH_3 + HNO_3 = NH_4NO_3$$

This reaction takes place in tanks lined with acid-proof brick, the ammonia gas being piped into the tanks from above. The product is a liquor containing about 45 per cent ammonium nitrate. This liquor after being freed from sediment is piped to the nitrate houses where the water is evaporated and the ammonium nitrate is finally obtained in granular form. It is then ready to be loaded in cars and shipped to powder plants.

During the time the plant was in operation about 1700 tons of high-grade ammonium nitrate were produced.

The Products and Their Utilization

During the war ammonium nitrate was used chiefly in the manufacture of amatol, a mixture of ammonium nitrate and trinitrotoluene in the proportion of 80 parts ammonium nitrate to 20 parts TNT.

Of the several products which the plant is capable of producing without any additional facilities, two are available for use as fertilizer material: cyanamide and ammonium nitrate. Although certain of its chemical properties have limited the amount that may be safely used in a ton of mixed fertilizer, large quantities of cyanamide have been used in fertilizer material. It can be produced at a lower cost than any other form of fixed nitrogen. Ammonium nitrate has not been used heretofore in commercial fertilizers to any appreciable extent. While it is entirely suitable as a plant food, its marked hygroscopic property is an obstacle to its use in fertilizers. If a way is found to overcome this property it will undoubtedly be in demand as a fertilizer material. The one product for which a market is at hand and which could be produced at Nitrate Plant No. 2 is ammonium sulphate. To manufacture this material it would be necessary to provide additional facilities at a cost of perhaps two million dollars. In case the plant is operated for the production of fertilizer material, ammonium sulphate will probably be the principal product until such time as a market is developed for other products.

The future of nitrogen fixation in the United States will depend in large measure on the relation between the demand and supply of inorganic nitrogen.

The world's production of inorganic nitrogen in 1910 was 654,000 tons. By 1913 it had increased to 823,000 tons and in 1918 it amounted to 1,300,000 tons. The increase in production was most rapid in the case of fixed atmospheric nitrogen and least rapid in the case of Chilean nitrate The war demand increased the Chilean production only ten per cent—from 450,000 to 500,000 tons. The production of by-product ammonia increased from 220,000 tons of nitrogen in 1910 to 390,000 tons in 1920. During the same period the production of fixed atmospheric nitrogen increased from 10,000 tons to 467,000 tons.

Table 1 shows the national production capacities for inorganic nitrogen other than Chilean nitrate in 1921. It will be noted that Germany leads with more than half of the world's total capacity. The United States, Great Britain, and France follow in the order named.

Approximately one-half of the inorganic nitrogen consumed in the United States at the present time is used in the production of fertilizers. The balance is about equally divided between explosives and the chemical and other industries. The consumption in fertilizers is increasing more rapidly than the consumption for other purposes.

The enormous increase in the use of inorganic nitrogen for fertilizers is due principally to the increased use of commercial fertilizers. To some extent, however, it is due to the replacement of organic nitrogen by inorganic nitrogen. Animal tankage, dried blood, and cottonseed meal, which in the past have furnished a considerable part of the nitrogen contained in commercial fertilizers, are being used more and more for cattle feed.

The total nitrogen returned to the soil each year by fertilizers is a fraction only of that annually lost from land under cultivation. As the natural fertility of the soil decreases and the value of farm lands and farm products increases, there should be a corresponding increase in the demand for fertilizers. It is not unreasonable to expect that the use of fertilizer will grow more rapidly in the future than it has in the past, providing only that it is available in sufficient quantities and at a reasonable price.

Assuming an increase of 10 per cent per year, it has been estimated[2] that the total consumption of inorganic nitrogen in the United States will be 291,500 tons in 1924 and 438,000 tons in 1930. The estimated domestic supply of by-product nitrogen from coal for the same years is 122,500 and 159,500 tons, respectively. The difference will have to be supplied by nitrogen-fixation plants and by imports. A considerable part of the deficiency—45,000 tons—could be obtained by the operation of United States Nitrate Plant No. 2.

Fig. 3 Catalyzers for Oxidation of Ammonia to Nitric Oxide

In the event of a future war, the requirements would be much greater. National preparedness, moreover, requires that the fixation of nitrogen be well established in the United States, so that in the event of a serious national emergency the country will be self-sustaining as regards the supply of nitratesa nd explosives.

The operation of the Muscle Shoals plant should contribute materially toward the building up of the nitrogen-fixation industry in this country.

Some Principles of the Construction of Unfired Pressure Vessels

By S. W. Miller,[1] Rochester, N. Y.

This paper discusses in general terms forge and fusion welding and riveting, and comments on the factors affecting welding efficiency. The composition of the best base weld metal and welding wire is touched upon and proper welding conditions mentioned. The weakness of the single "V" weld is pointed out and the use of lower-tensile-strength material advocated. The question of relieving welding strains by annealing is also treated and these and the foregoing observations are all based upon the practical experience of the writer. In considering the relative merits of welded and riveted tanks a specific instance is cited to show the superiority of the former. The results of testing welds in a Strohmenger alternating bending impact machine are also given.

There are two appendices to this paper. In Appendix No. 1 the details of the testing of ten specimens of welded plates and the results are presented along with the author's comments and conclusions. Appendix No. 2 deals with the testing of four half-inch plate-steel and two Armco iron welded tanks. The details and many photographs in both appendices capably illustrate the results and conditions under which the tests were conducted.

THE use of containers or vessels made of various materials for holding gases and liquids under pressure has been a common practice for many years. These vessels have been made of all kinds of material and with or without joints as conditions and the fancy of the designer controlled. The vessels carrying heavy pressure have been usually, in the past, of riveted construction, although forge welding of such vessels, or parts thereof, has been practiced for a long time.

Forge welding is expensive and therefore not suitable for many types of vessels. Riveted joints have also been used because of their ease of construction and of the certainty with which their efficiency may be calculated. Much of this certainty is due to our long acquaintance with them; to the many tests that have been made on them, and to the fact that they may be readily inspected both during and after their manufacture. From a construction standpoint, however, riveted joints are objectionable for many reasons, among which is their decided tendency to leak.

It must be always kept in mind also that many failures have occurred with riveted construction and that such construction is not as simple a matter as it would appear, if one were to be guided entirely by what is sometimes said. The fact of the matter is that in the case of a great many people, familiarity with riveted construction has developed a sort of contempt for the dangers accompanying it. It is only necessary to recall the protests that were made against the restrictions on double-riveted lap joints in the A.S.M.E. Boiler Code to see that this is true.

Of recent years fusion welding of such vessels, usually in steel plate or sheet, has been used to a very great extent, the welding generally being done by the oxy-acetylene or metallic-electrode arc processes. These processes, when properly applied under proper conditions, produce a safe structure that has great advantages in regard to cost, lightness, strength and freedom from possible leakage.

Single Objection to Fusion Welding

The only objection that can be raised against vessels made by fusion-welding processes is that the integrity of the weld depends very largely on the honesty and ability of the welder, because it is very difficult, if not impossible, to inspect the weld satisfactorily. This fact, coupled with accidents that have occurred have created in the minds of many a suspicion that fusion-welding processes are not safe and that pressure vessels made by their use should be condemned.

Unfortunately, it is true that there have been accidents of a more or less serious nature from defective welds, or from those improperly made. It is equally true and equally unfortunate that vessels whose parts have been joined by other means than fusion welding have been equally productive of accidents, if not more so; and while it is also true that failures of seamless vessels have occurred, yet the advocates of fusion welding cannot rely on any such statements to help their case.

The real difficulty in the case of fusion-welded pressure vessels is that the art is so new that it has not been reduced to standard practice. The first welding torch was patented in 1903 and the progress of the art was very slow at first. Really the welding of pressure vessels has not been in use to any great extent for more than 10 or 12 years, and it is hardly to be wondered at that the knowledge of the art is limited compared with the knowledge of riveted joints and of the best methods of making them. Undoubtedly, when fusion welding will have been in use for as many years as riveting, those living at that time will wonder why there was any question of the value and safety of fusion-welding processes.

But on those of us who are living now and who are interested in fusion-welding processes, lies the burden of devising means and ways of producing safe vessels, to which we can point with satisfaction and pride as being not only the equal of other constructions but far superior to them.

The two main points of superiority in such vessels are their freedom from leakage and their much greater efficiency of the joint. As in other developments of mechanical and industrial processes, much has been done in the way of fusion welding by cut-and-try methods, and those of us who have been in the business for years can testify to the difficulties encountered. These troubles only stimulated the enthusiastic worker, and methods were developed which overcame many of them, but at great expense and loss of time.

Welding Efficiency

When welding began to be studied in a more careful manner, much was said about the efficiency of a weld, i.e., the ratio of the strength of a weld to the strength of the material of which it was made.

In what follows I feel that it will be well to limit discussion to vessels made of steel plate or sheet, because it is this material and vessels made of it with which we are principally concerned. I believe, however, that the principles which I shall attempt to develop are equally applicable to other materials.

It was found by trial that the efficiency varied greatly, ranging from as low as 20 per cent to as high as 95 per cent, and sometimes higher. There was much discussion as to what percentage should be used for the design of welded pressure vessels, and it was not to be wondered at that with the wide variation in efficiency no agreement could be arrived at as to what value should be assigned to the weld.

After considerable study and experiment I arrived at the conclusion that it would be necessary to eliminate the consideration of this variable and unknowable efficiency, by either making the weld so strong that rupture could not occur there, or by making the plate so weak that rupture would occur there always. It may seem that these two statements are the same, but they are not, as will be explained later, and it has finally become very clear to me that the second statement is the basic principle for the construction of safe welded pressure vessels.

Factors Affecting Weld Efficiency

It is easy to see that the efficiency of a weld may vary for different reasons—the welder may be inefficient, the welding material may be poor, the torch or electrode may not be capable of proper operation; but beyond all these things is the fact that the mate-

[1] Proprietor, Rochester Welding Works. Mem. Am.Soc.M.E.

Abridgment of a paper presented at the Spring Meeting, Atlanta, Ga., May 8 to 11, 1922, of The American Society of Mechanical Engineers. All papers are subject to revision.

rials, or base metals, which have been used for making tests vary very widely in strength. One test may have been made with 50,000-lb. material, another, with material of 65,000 lb. tensile strength. With the same welding material and the same operator the weld metal in the two cases should have the same strength. If we assume this at 50,000 lb. tensile strength, the weld in the low-tensile-strength plate will have efficiency of 100 per cent, while in the high-strength plate the efficiency would be about 77 per cent. Evidently, these two results cannot be compared unless the strength of the base material be considered. Therefore one of the first things to do is to decide what kind of material to use for the base metal.

It has been known for years that forge welding gives best results in low-carbon material, and on the other hand, tool steel is difficult, if not impossible, to forge-weld if full strength is desired. This is natural, because the high-carbon steel is easily burned at a temperature that will injure the low-carbon material but little.

In the course of my investigations I found several years ago that in two very large shops where fusion welding was one of the most important processes, they were using material of this character and had had splendid success with it. I have made numerous tests on various kinds of steel plate and found in these tests that the best welds were made in material of the same general character, that is, low-tensile-strength plate.

Composition of Best Base-Weld Metal

I have therefore come to the conclusion that the base metal most successful for welding is of about the following chemical composition:

Carbon, per cent	0.15 max.
Manganese, per cent	0.60 max.
Sulphur, per cent	0.05 max.
Phosphorus, per cent	0.04 max.

It should have about the following physical characteristics:

Tensile strength	50,000 lb. max.
Yield point	at least half tensile strength
Elongation, per cent in 8 in.	$\frac{1{,}500{,}000}{\text{tensile strength}}$.

Further investigation showed, much to my surprise, that material of this composition and strength would not always weld well, and I believe I have demonstrated that there is something more necessary than the above specifications if the most satisfactory material is to be obtained.

The microscope shows that steel which welds badly contains large numbers of small non-metallic impurities, which are probably oxides or silicates, because the percentage of sulphur is too small to form so much manganese sulphide. This indicates poorly made steel and evidently the coöperation of the steel maker is needed if we are to have satisfactory material with which to work.

I have occasionally found that improperly annealed steel also gives trouble in welding even in the absence of non-metallic impurities, but not to such an extent.

I have no hesitation in saying that steel of the above chemical composition, if free from non-metallic impurities, is the best metal, in my opinion, for the making of pressure vessels.

There is another reason for this statement and it lies in the fact that such material is very ductile, and will stand punishment in the nature of overheating or mechanical work that higher carbon steel will not stand, and inasmuch as there are always strains in welding due to the contraction of the heated metal, any material that will stand these strains and absorb them is much superior to one that will not.

Much trouble has been experienced in welding long seams in such high-carbon material as ship plate, and much credit is due to those who have exercised ingenuity enough to overcome this trouble; but it is much easier, cheaper, and safer to avoid it than to overcome it, and all my experience shows that the use of the material suggested will avoid the trouble.

Welding-Wire Composition

The welding wire ordinarily used for gas welding is a low-carbon material of about the following composition:

Carbon, per cent	0.06 max.
Manganese, per cent	0.15 max.
Phosphorus, per cent	0.03 max.
Sulphur, per cent	0.03 max.

It is a very carefully made product and of superior quality, and gives very good results. In half-inch plate of sufficient strength to break the weld, it gives a tensile strength of about 52,000 lb. per in. in a double "V" weld when the weld is of equal section with the plate. I do not believe that it is strong enough, however, to allow for welds that are somewhat imperfect, if it is desired to always break the plate and never the weld.

I have therefore advocated low-carbon nickel-steel wire of the following composition:

Carbon, per cent	0.15 to 0.25
Manganese, per cent	0.50 to 0.80
Sulphur, per cent	0.045
Phosphorus, per cent	0.04
Nickel, per cent	3.25 to 3.75

This corresponds to the Society of Automotive Engineers' specification No. 2320. This material tested under the same conditions as the ordinary welding wire above mentioned, gives a tensile strength of from 57,000 lb. to 63,000 lb. in the weld.

Another Good Welding Wire

I have no doubt that other equally good or better welding materials can be devised. I know of one that is better in some respects, but it is not quite ready for the market. Tests made with it have shown an average in 12 tests of 62,400 lb. with a maximum of 64,500, and a minimum of 58,600, so that the results are quite uniform.

It should be clearly understood that I am not presenting the claims of any particular materials, but am only giving the results of my personal experience. I am advocating very strongly the use of a welding material of such character as will most easily make a sound, clean weld, of a base metal that is weak enough to absorb the welding strains and to break always outside of the weld, and of methods that will always insure these results.

Under the head of methods, the type of weld is of importance. I have demonstrated to my own satisfaction that a single "V" weld is never as strong as a double "V" weld. The latter requires twice as much welding material and is therefore more expensive. A single "V" weld cannot usually be bent backward, i.e., with the top of the "V" concave to the bend. Under such a test the chances are very great that the break will take place through the center of the weld. The reason for this is that it is impossible to get freedom from defects at the bottom of the "V." This is shown clearly by the photographs.

Weakness of Single "V" Weld

Iron oxide melts at a lower temperature than the steel, and it flows down the side of the "V," accumulating underneath the edges due to its surface tension, and when the welding rod is applied there is a film of oxide at the bottom of the "V" or under it, over which the melted metal flows, leaving a line of weakness. It also works up more or less into the bottom of the "V," leaving cracks which are frequently microscopic but none the less dangerous.

According to my observation, the ruptures of welds, not only in pressure vessels, or steel plate or sheet, but in cast iron and other metals, have been with single "V" welds. I do not recall a case of a double "V" welded piece giving way in the weld. We never use a single "V" weld if it is possible to use a double "V," even if it is necessary to weld overhead to make the bottom of the "V" sound.

Of course, where there can be no bending, as in the case of a convex head welded to a shell, there is no particular danger, especially as the fiber stress is low. Also, if the double "V" weld cannot be used for any reason, there can be no argument, but the stress must be kept at such a point as will be safe, or the design changed to permit the use of the double "V."

A double "V," on the other hand, permits of the burning out of these defects, and if any do remain, they are in the center of the weld, where their only effect is to slightly reduce the tensile strength, which can be compensated for by increasing the thickness of the

weld. This cannot be done with the single "V," because increasing the thickness of the weld on one side increases the fiber stress due to a given pressure, on account of the eccentricity of the load. This can be readily seen in the testing machine, because the test piece bends toward the bottom of the "V."

Proper Welding Conditions Essential

The use of a double "V" may not be necessary in all cases, but for all important work I am satisfied that it should be used. With double "V" welding it is necessary to clean the scale carefully from the second side welded before welding. This scale comes from the action of the air on the red-hot metal during welding of the first side, and if it is not removed it will get into the weld and make it weak and brittle. There are two reasons for this: First, melted steel will dissolve quite an amount of oxide just as water dissolves salt, but on cooling, when the metal crystallizes, it rejects to the boundaries of the grains much of this foreign material, and as it has no strength, the metal is injured; second, if the oxide is present in large enough amounts, it is included in the weld, unless great care be taken to float it to the surface of the metal during the welding, with the same result as before.

I might speak here of the necessity of forcing to the surface all foreign material during welding, as in my opinion this is an important source of defective welds. Another difficulty, which is really the same thing, is allowing melted metal to run over on to metal that has not been fused. As the latter is always covered with a coat of oxide, the result is a weak spot in the weld. It should also be noticed that the thicker the material being welded, the more liability there is of any or all of these defects occurring, and this is one reason for my belief that we should not, at the present time, attempt to use material of a greater thickness than $^5/_8$ in. for making fusion-welded pressure vessels.

Regarding the thickness of material, it should be noted that a single "V" weld in material $^5/_8$ in. thick, using a 90-deg. "V," is $1^1/_4$ in. wide. It is not possible to protect all this surface at once with the welding flame, or with the gases from the arc, and the very hot metal comes in contact with the air and is coated with oxide. The weld metal has to be remelted more or less, the amount of remelting and oxidation increasing as the thickness increases.

Again, a single "V" weld is seldom welded through, even in the best welding shops, because objection is made to any drops projecting from the inside, for reasons which are sometimes good and sometimes bad. And as it is difficult, if not impossible, to avoid these projections, the welder stays away from the sharp edges of the "V," which melt away readily, and ball up due to the surface tension of the melted metal. This balling up results in a wide opening at the bottom of the "V," which is hard to fill up. The result of not going through is an unsound weld at the bottom of the "V."

Oxides Cause Rupture

It may not be out of place to say a few words about the bearing of oxides on the weld strength. I have shown[1] that the path of rupture in steel fusion welds is first initiated at visible inclusions. If there are none of these, the next place they begin is at the grain boundaries, even when no foreign matter can be seen there at the highest power of the microscope. This is true in both gas and electric welds. It is known that such welds are overoxidized, and the inference is fair, I think, considering this and other evidence, that oxides are the cause of the intergranular rupture. It is evident that every effort should be made to keep welds as free from oxides as possible. Tests indicate that the tensile strength of an oxidized weld in $^1/_2$-in. plate is about 43,000 lb. per sq. in. The yield point of the specified base metal would be something over 25,000 lb. per sq. in., so that there is quite a margin of safety in a poor weld, as far as tensile strength is concerned, even when the weld is no thicker than the plate. It is commercially possible to reinforce a weld 15 per cent on each side, so that its section will be 30 per cent greater than that of the plate. Therefore the tensile strength of a poor weld reinforced would be, referred to the plate section, say, 55,000 lb. per sq. in., or more than that of the plate. I therefore conclude that a reasonable reinforcement of the weld is necessary for safety. The above figures are based on the use of straight low-carbon-steel welding wire. If higher-strength material be used, the margin of safety is still greater. For example, the average tensile strength of the special wire welds referred to is 62,400 and the minimum 58,600 referred to the weld section. A 30 per cent increase would mean an adjusted plate strength of about 76,000 lb. per sq. in., which is much higher than the upper limit for ship plate, 68,000 lb. From a design standpoint it is of course desirable to use as strong a plate as possible to make the vessel as light as may be. But we must be sure that the plate is always sufficiently weaker than the weld, and allowance must be made for the defects that cannot be avoided in practice.

I would again speak of the danger of assuming a weld value in design that is based on a plate stronger than the weld. Such a value is pure assumption, in spite of tests, because no account can be taken of the unknown strains in the sheet. If, on the other hand, the plate is purposely made enough weaker than the weld, there can be no danger of the weld giving way under any circumstances. If it can be shown that this can be done under usual shop conditions, it would be fair, I believe, to assign a high weld value to such construction. It should be kept clearly in mind that weld values have been in the past taken from welds made on different principles than those here advocated, and that they cannot be applied fairly under the proposed conditions. It is as if a riveted joint could be designed that had 150 per cent of the plate strength. Surely it would not be fair to assign to such a joint an arbitrary efficiency of 70 per cent.

There must be a limit to the tensile strength of a weld, and in my judgment the margin by which the plate strength should be less than the weld strength is not known with sufficient exactness to permit of any general statement being made as to its amount.

Lower-Tensile-Strength Material Advocated

Assuming that a weld 30 per cent stronger than the plate is enough to allow for usual defects in the weld, and that such a defective weld will always break the plate, we might assume that we could safely use 65,000-lb. plate, and would be safe if the weld tensile strength were 65,000 lb. per sq. in. and if it were reinforced 30 per cent. This would be true theoretically, but I am afraid of practical difficulties. The welding strains would not be absorbed by the plate as readily as with softer base metal, and there is doubt in my mind as to the welding qualities of such plate. I am strongly of the opinion that these difficulties are absent in the case of the suggested base metal. Therefore, it seems to me that till such tests have been made as will show beyond question that the use of high-tensile-strength plate is safe, we should use lower-tensile-strength material which is known to be satisfactory. It is important, however, to determine in the near future the possibilities of higher-tensile-strength material than that specified.

One precaution that should always be taken for important work is the rerolling of the shell after it is welded. The reasons for doing this are that it is impossible, particularly with heavy sheets, to roll them truly round at the ends, and the flat spots that are left there are liable to cause trouble when the vessel is put in service, due to its tendency to assume a circular section under pressure. This puts a bending stress on the weld which it is not well suited to resist, while if the shell is rerolled, the strain becomes tensile. Further, it tends to relieve the welding strain, if not to entirely remove it, and to locate defective welds.

Relieving Welding Strains

The question of annealing pressure vessels after welding, in order to relieve the welding strains, is one about which not much is really known. It would seem to depend partly on the thickness of the sheet. The thin sheet will readily distort during the welding and relieve the welding strains, while a thicker one will not do this so easily. This is another reason for limiting the thickness of the material. Another thing that influences the strain is the diameter of the shell, as a large shell will accommodate itself to the strain more readily than a small one of the same thickness.

The annealing of a pressure vessel may mean several things: First, heating of the weld and its vicinity to a sufficient temperature to relieve the welding strain; second, the annealing of the

---

[1] Path of Rupture in Steel Fusion Welds. Paper read before the A.I.M.E., Feb., 1919.

weld metal to reduce the grain size to make it more ductile; third, the annealing of the metal next to the weld to remove the coarseness of the grain produced by the welding heat. There may be also combinations of any two or all three of these treatments. It should be clearly understood, however, that the temperatures for the three treatments mentioned are entirely different. The temperature for relieving the welding strain does not need to be more than a very dull red, say, not over 900 deg. fahr., and even this may not be necessary, as is shown by the fact that many cast-iron pieces are welded successfully without being heated to a dull red.

The refining of the grain in the base metal requires a higher temperature, which must be above the upper critical or Ac$_3$ point. This temperature varies with the chemical composition of the steel, particularly as regards its carbon content. This temperature for the steel specified in this paper is about 1525 deg. fahr.

The chemical composition of a weld varies not only with the composition of the welding wire, but also with the method of its making. However, a gas weld made with ordinary straight carbon-steel wire has a very low carbon content, not much over 0.04 per cent, and for forged material, steel of this composition would have an Ac$_3$ point of about 1625 deg. fahr.

It is well known, however, that a casting requires a higher refining temperature than a forging of the same chemical composition, and by test I have found[1] that a gas weld made as described has a refining temperature of about 1750 deg. fahr.

In an electric weld made with bare wire there is a large percentage of nitrogen, in some cases as high as 0.14 per cent, while the other elements are usually present approximately in the same proportions as in a gas weld.

The presence of nitrogen entirely changes the critical points, and in the case of such a weld they appear to be absent. This does not mean that the structure of an electric weld cannot be altered, but it does mean that the temperature would have to be determined by experiment.

In the case of nickel-steel welding wire, the weld contains over $2^1/_2$ per cent of nickel. Nickel lowers the upper critical point, depending on the amount of nickel present—in this case, about 50 deg. fahr.

It will therefore be seen clearly that annealing for any purpose except relieving the strains is impossible from a commercial point of view, as it would involve a double heat treatment.

It is evident that it is not necessary to heat the whole vessel for the purpose of relieving the welding strains, and probably a dull red heat for a distance of 2 in. or 3 in. on each side of the center line of the weld in $^1/_2$-in. material would be sufficient.

It is doubtless true that either annealing and rerolling can be omitted in some cases, and that neither of them would be required for safety in other cases. But it seems clear that the higher the tensile strength of the plate, the greater the necessity of taking these precautions. A further reason for using low-carbon sheet is that it is not liable to be injured by the welding heat as much as higher-carbon material.

It may be objected that the carrying out of these principles will be so expensive as to make it commercially impossible to use fusion welding for pressure vessels. There are two answers to this. First, the burden of proof of the correctness of the statement rests on those who make it, and until proof is given of its correctness, the mere assertion is not evidence. Second, if it be true in any case that safe practice (and this does not of necessity include all the precautions mentioned for every case), makes welding too expensive, then it is obvious that welding cannot be used.

Further, there is involved the matter of salesmanship. If we believe that a properly welded vessel is better and safer than a riveted one, we should be able to sell it in all cases where it is worth the price, and if it were not worth the price, we could not honestly urge its installation.

It is quite possible that poorly welded pressure vessels are much cheaper than well-riveted ones, and that this has been used as a means of reducing prices in some cases. But if this be true, those responsible for the poor welding cannot come into court with clean hands, and their arguments would be invalid. Fortunately, such arguments are rarely heard, but unfortunately, we must make specifications which guard against such possibilities.

Welded vs. Riveted Tanks

It may be of interest to consider the relative merits of welded and riveted tanks as far as strength is concerned. Only one instance will be given. Assume the riveted tank to be double lap-riveted of $^1/_2$-in. plate of 60,000 lb. tensile strength, and 5 ft. in diameter. With a factor of safety of 5, it would be good for 140 lb. working pressure by the usual formula. If the welded tank were of the same dimensions of 50,000-lb. plate, with a weld strength of 125 per cent of the plate, which is easily obtained, it would be good for 141 lb., if a weld efficiency of only 85 per cent were assumed, using the same factor of safety and formula. I really believe that the welded vessel is far superior to the riveted one in this case, in every way.

Objection has been raised to the use of welding because of the small resistance of welds to alternating stresses and shocks, to which any pressure vessel is subject in service. It is true that if the base metal is stronger than the weld, the weld readily gives under such stresses, but it does not seem to be so if the base metal is weaker.

In order to determine whether the ideas which I held were correct, a number of welded plates were tested and then later further tests of actual pressure vessels were conducted. The complete results of both sets of tests are presented in the appendices to this paper, selections from which appear in the present abridged publication.

Also through the courtesy of the Quasi Arc Weldtrode Co. a number of tests were made in their Strohmenger alternating bending-impact machine, especially designed for testing welds. The test piece, $^3/_8$ in. by $2^1/_2$ in. in section, with the weld machined flush with the base metal, is clamped in the jaws, with its edge level with the center of the weld. The vibrating head is loose on the test piece, the opening being $^1/_2$ in. wide. The head travel is so adjusted that the test piece bends $^5/_{32}$ in. on each side of its central position, so that the travel before impact is $^1/_8$ in. and the total bend $^5/_{16}$ in. The number of alternations is about 600 per minute. Of course, no quantitative results can be obtained, but the results were quite consistent in the forty-two tests which were made.

One set of tests was made with two welding wires, an ordinary low-carbon steel, and 3.5 per cent nickel steel. Two base metals were employed, and 3 test pieces were made with each combination, a total of 12. The results of this series were as follows:

Base metal	Welding rod	Average no. of alterations before rupture	Broke
57,000 lb. tensile strength, bar steel	Carbon steel	3300	all in weld
57,000 lb. tensile strength, bar steel,	Nickel steel	5600	all in weld
47,000 lb. tensile strength, plate,	Carbon steel	4550	all in weld
47,000 lb. tensile strength, plate,	Nickel steel	8550	all out of weld

These results show clearly the superiority of the low-strength-plate—high-strength-weld combination. It might be said that the unwelded plate gave about the same results as did the nickel-steel welds.

It seems clear that the stiff nickel-steel weld threw the strain into the soft plate, which broke just next the weld in the zone coarsened by the heat, and if this zone has about the same resistance as the solid plate, as the tests indicate, there can be little fear of danger from alternating stresses in service in a vessel made in the same way. It should be remembered, however, that the higher the tensile strength of the plate, the higher the carbon content, and therefore the greater danger from the welding heat, especially if the heat be applied rapidly and the cooling occur quickly. This has resulted in ruptures in heavy boiler plates, say $1^3/_{16}$ in. thick, due to the formation of a sorbitic zone next the weld, and to the strains set up in the sheets by the weld shrinkage. This trouble can be avoided by preheating sufficiently to avoid forming sorbite, which requires a rather rapid rate of cooling for its formation. This sorbitic condition would doubtless have an effect on alternating-stress tests, and such tests should be considered a necessary part of any program for studying the value of plate for welding purposes.

APPENDIX NO. 1

TESTS OF WELDED PLATES

In order to determine whether the ideas which I held regarding fusion welding of unfired pressure vessels, were correct, I took up the matter with H. S. Smith, then president of the International Acetylene Association and Prof. C. A. Adams, director of the American Bureau of Welding, and with their coöperation a number of tests were conducted.

Altogether there were ten plates tested and a summarization of the general results is given in Table 1.

Specimen B, from the York Mfg. Co., was purchased with the understanding that it was same general type of material as the others, but on analysis it was found to contain 0.24 per cent carbon and to be of about 64,000 lb. per sq. in. tensile strength. The ground test piece broke in the weld at 58,000 lb. Another cold-bend test piece of another exactly similar weld in another plate of the same material broke outside of the weld and the hot-bend test piece bent flat on itself, without cracking.

Fig. 1 Cracks in Weld of Specimen B; Magnification 2.3

Probably the most interesting case of the ten specimens tested is that of specimen B, in which cracks were found in the plate at a distance up to $^3/_4$ in. from the edge of the weld, which could frequently be seen with the naked eye and which were readily visible with a magnifying glass (Figs. 1 and 2). It should be noted that the plate had not been fused where the cracks occurred. Examination was made of these cracks by taking a section through them and examining under the microscope.

The pieces so examined were taken from another test plate made of the same steel and in the same way, the test pieces having been strained in a 50,000-lb. testing machine, which was not sufficiently strong to break them, but which did open up the cracks referred to so that they could be seen. These cracks (Fig. 3) apparently only occurred on the second side welded, and are probably caused by the resistance to shrinkage due to the stiffness and strength of the plate, although the poor general quality probably had also a considerable effect. I had never noticed such cracks before, although I have since found them in sheet material of poor quality.

Microscopic examination of the section taken through one of these cracks is very interesting. The plate, as received, was quite heavily coated with mill scale, which had been rolled into the surface. This is brought out by the pickling. An examination of the weld with a hand glass shows quite clearly that this mill scale has been fused in the vicinity of the weld. Of course the temperature of the plate near the weld was high, probably 2300 deg. fahr. or 2400 deg. fahr., which would be sufficient to melt the scale. Also the plate at that temperature was in the γ range.

At this high temperature the crystallization of the metal is different from that at room temperature in that the grains are of different shape and larger, and that the carbon is all in solution in the iron. The weld having been made on one side, the plate is rigid and the expansion due to the heat compresses the metal where it is weakest, that is, hottest, and when it cools the contraction occurs at the same place. If the strain is great enough, the plate cracks if it is not sufficiently ductile. If the metal were of poor quality, and brittle at high temperature, the condition would be worse. In either case, capillary attraction might draw the melted scale into the cracks.

At this high temperature the solvent power of the iron for impurities is considerable, and it is quite reasonable to suppose that some of the mill scale was dissolved. As the metal cools, some of the oxide would fall out of solution, and be rejected to the grain boundaries then existing, that is the austenite or γ ones. Even if this did not occur, the strain might cause minute cracks, the surfaces of which would oxidize easily. Whatever occurred, the recrystallization that took place later in the cooling, when the metal passed from the γ to the α condition, could not pass these impurities, which outlined the γ grains, and which, when the metal was cold, showed their location.

It is well known that tool steel, when burnt, shows such markings around the grains, these being sharply angular instead of being rounded as the alpha grains are. I sectioned one of the pieces through one of these cracks in the plate, and in examining it at low power I noticed a network which did not coincide with the α grain boundaries. Higher power showed it to be apparently a film of oxide. Still higher power seems to confirm this.

Microphotographs are given showing the structure. Fig. 4 shows that the network is quite extensive, being to the right of the large crack which is the result of the tensile test of the material. I have no doubt that originally this crack was not much larger than the network. Fig. 5 shows part of the network at a higher magnification, and Fig. 6 at still higher power. Figs. 5 and 6 show quite clearly that the pearlite and cementite do not lie at the films and in some case the α grain boundaries can be readily seen. They are clearly different and distinct from the films.

A section from sample No. 1 of specimen B showed no cracks in the plate, but some few in the weld, which were about 1/200 in. deep. In some cases it appears that these cracks pass through the center of particles of cementite as shown in the photograph (Fig. 7). Whether the cementite was actually ruptured or not is a question, although I am inclined to think that it was. This would require the rupture to have occurred, at least partly, below the Ar_1 point. It is of course, possible that the main part of the crack occurred at high temperature and that it extended at a lower temperature. These cracks are very small and have no apparent effect on the strength of the welded piece, because even when the welds were ground down level with the plate, the plate broke in the middle third between the weld and the shoulder in a natural, normal manner.

These cracks are also very shallow, and most of them are filled with oxide, showing that they occurred at high temperature. The weld scale is very adherent, requiring for its removal much longer pickling in dilute hydrochloric acid than ordinary weld scale. It appears to run down into the cracks as a continuous part of the surface scale in some cases, and there are in the surface scale particles of metal.

Sample No. 2 of specimen B appeared from general observation not to be of good steel. The fractures in the tensile test pieces were not silky as they should be, but were more or less harsh to the eye. It is worth noticing that welds made with nickel steel wire, in 64,000-lb. plate, the welds being reinforced the usual amount, broke the plate outside the weld with the same necking down as would be expected in an ordinary tensile test.

Leaving aside for the moment the question of welding, it would seem that we must pay much more attention to the quality of the steel used for welding than we have in the past, and this brings up the question of some of the mysterious failures of boiler shells, ship plates, etc., and I am inclined to believe that much of the trouble has come from defective steel; the defects have not been detected, and they probably could not be detected, by any ordinary examination or the regular tests.

There was, for instance, the quite noted case[1] of the plate failures on a ship being built in England, which gave trouble from brittleness after having passed all Lloyd's tests successfully. This case was investigated by some of the ablest metallurgists in England, and the consensus of opinion appeared to be that the plate was from a basic open-hearth heat that had not been properly treated with manganese and was otherwise badly made.

Attention was called to the remarkable angularity of the grains. It was found by analysis that the steel was very high in oxygen and nitrogen.

TABLE 1 RESULTS OF TESTS OF WELDED PLATES

Specimen	Sample	Lb. Per Sq. In.		Per Cent		Weld Ground	Location of Break
		Tensile Strength	Yield Point	Elongation in 8 in.	Reduction of Area		
A	1	50,900	32,400	25.7	.....	no	3 in. from weld
	2	50,500	31,400	27.1	.....	yes	2½ in. from weld
	4	51,000	32,000	29.0	.....	yes	3 in. from weld
B	1	58,500	43,100	4.25	.....	yes	In weld
	2	64,000	41,300	19.6	53.6	no	1½ in. from weld
	4	63,700	41,500	23.5	53.1	yes	3 in. from weld
C	1	29,750	27,300	2.3	4.2	yes	In weld
	3	31,700	27,100	3.4	4.7	yes	In weld
	5	41,100	27,100	6.6	10.6	yes	In weld
D	1	48,100	30,500	26.0	4.5	yes	2 in. from weld
	3	47,250	30,300	27.0	3.2	yes	2 in. from weld
	5	49,100	29,100	29.7	2.9	yes	2 in. from weld
E	1	51,100	32,930	31.0	59.0	no	1½ in. from weld
	2	51,680	32,700	26.6	58.4	yes	1½ in. from weld
	4	51,320	32,000	25.0	61.2	yes	Outside of weld
F	1	42,570	.....	21.9	61.15	yes	Outside of weld
	3	43,210	.....	25.9	63.1	yes	Outside of weld
	5	43,010	.....	21.0	61.5	yes	Outside of weld

[1] The Remarkable Failure of a Consignment of Ship Plate, by J. B. Wilson. Proceedings of Engineers & Shipbuilders in Scotland, 1914, p. 227.

Analyses were made by a number of chemists and the results not only showed the above, but that the steel was badly segregated. While the standard tests did not show anything wrong with this material, alternating-stress tests did show clearly that the metal was inferior, and the matter is referred to, not with the idea of trying to include such tests in specifications, but to show that at times more searching tests than the usual ones may be needed.

In many other cases in the literature this same angularity of grain is noticed in photographs, even if no reference is made to their shape in the text, so that angular grains would be indicative of poor material. It would seem that they represent the γ grain boundaries, and not the α ones.

I do not doubt that invisible intergranular films may exist along the γ grain boundaries in many cases, which would open paths for oxidation when heated or which under severe strain might result in rupture, particularly if the strain were accompanied by shock. I am convinced that such is the case in welds, because I have broken many pieces under the microscope, and even where there was no evidence of intergranular films at 1200 diameters, the rupture was generally along what are apparently the γ grain boundaries.

TABLE 2 A.S.T.M. SPECIFICATIONS FOR FLANGE AND FIREBOX STEEL

Kind of Steel	Flange Steel	Firebox Steel	Remarks
Carbon, per cent	.	0.12 to 0.25	Plates $\frac{3}{4}$ in. thick or less
Manganese, per cent	0.30 to 0.60	0.30 to 0.50	Plates $\frac{3}{4}$ in. thick or less
	0.30 to 0.60	0.30 to 0.60	Plates over $\frac{3}{4}$ in. thick
Phosphorus, per cent	0.05 max.	0.04 max.	Acid
	0.04 max.	0.035 max.	Basic
Sulphur, per cent	0.05	0.04	
Tensile strength	55,000 to 65,000	52,000 to 62,000	lb. per sq. in.
Yield point	0.5 ten. strength	0.5 ten. strength	
Elongation in 8 in.	$\frac{1,500,000}{\text{ten. strength}}$	$\frac{1,500,000}{\text{ten. strength}}$	Minimum per cent

There are three classes or qualities of steel plate, called flange, firebox and tank. The specifications[1] of the American Society for Testing Materials for the first two are given in Table 2.

Steel of tank quality has no specification. It may have as high as 7500 lb. tensile strength and be full of impurities, and is entirely unfit for important work. It is made from heats that for some reason are off.

Firebox steel is evidently of better quality from its composition, having less phosphorus and sulphur. But there are further differences that are hard to describe, and which are usually known only to the mill. For much work, flange quality is plenty good enough, while for the better work, firebox quality is needed; but in my judgment the tensile strength and carbon are too high in the A.S.T.M. specification for really important work, and the specification proposed earlier in the paper I believe to be much more suitable. In any case, high quality is essential to the best work, and for such work firebox steel should be specified.

This matter of quality, as distinguished from chemical composition, has been referred to at some length, because my experience has been that it affects the quality of the weld. This is especially true where the metal contains notable amounts of what Brearley calls "mechanical dirt." It is coming to be believed more and more that oxides of various kinds are largely responsible for the poor quality of steel, and I have found that steel containing this dirt foams and spits during the welding, and that the welds made in it are weak. Of course all steel plate contains some impurities, and it is very hard to say how much to allow, or how to draw a specification limiting the amount. But steel of firebox quality never gives any trouble, as far as I know, and I believe that we will be safe if we specify it for important work.

Fig. 2 Crack in Both Plate and Weld of Specimen B; Magnification 3.2

The superficial cracks in the nickel-steel welds referred to are not found in all cases, and they are rare in welds made with ordinary materials and their presence is not fully understood.

The important thing is to provide a weld that will be sufficiently strong even when somewhat defective, and the base metal so weak that it will take the strain in preference to throwing it in the weld. I do not believe that these minute cracks in nickel-steel welds are any different from those occurring with ordinary welding material. This is not saying that welds free from them are not desirable because they are, but nickel steel should not be condemned on this ground alone, any more than should ordinary welding material, because the cracks have occurred in both.

The cracks in the plate of specimen B are of particular interest, because they show necessity of having the base metal of such a quality as will not be injured during the welding, and it is significant that none of the other plates had them, though they were looked for very carefully. We must not forget that special materials have had to be developed for specific processes, for instance, the use of bessemer steel is general for screw-machine stock, because the chips from it break up readily and do not clog the tools. In the same way, we must have for welding purposes a steel that meets the requirements. Fortunately, such steel is not difficult to obtain, and the steel maker will be glad to furnish it if he knows what the requirements are, and it is our business to advise him of them.

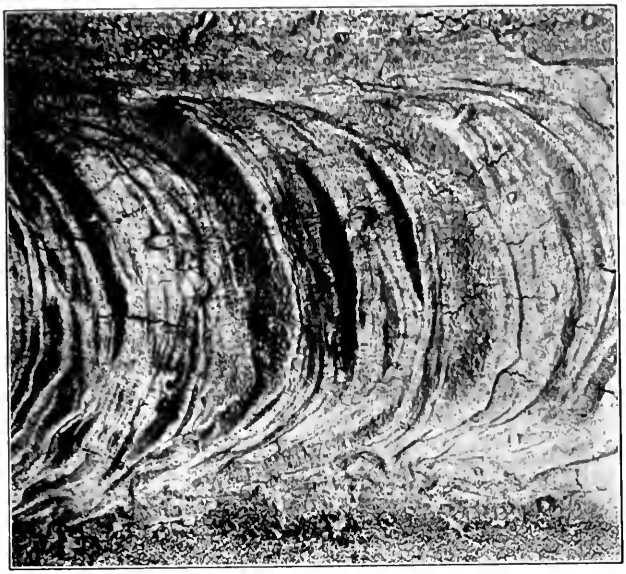

Fig. 3 Cracks in Weld and Plate After 50,000-lb. Tensile Load Failed to Break Test Piece. Scale Pickled off Before Taking Photo; Magnification 3.6

Any welding wire used must be of good and uniform quality if good results are always desired. I have found very bad results from some nickel-steel rod. I cannot say yet where the trouble lies, but it does not appear to be entirely dependent on the chemical analysis, and I have no doubt that the general quality of it and other wires will be found just as important in all cases as I know it is in some.

It should be clearly understood that I do not believe nickel steel to be the best welding material that can be made. I have had great success with it, and it is to my mind the best material now readily available for high-strength welds. But I would be glad to see other wire giving similar high strength, because it is very probable that still better qualities can be obtained by other alloys than nickel. It is just as important to have suitable wire for welding pressure vessels as it is to have suitable plate, and if our needs are realized they will be met.

I feel very strongly that some method of protecting the weld from the action of the oxygen in the air or in the welding flame must be used, if we want the highest efficiency. I do not mean that we cannot make safe pressure vessels now, because we can and it is being done every day, but we want to do better.

The following general conclusions may be drawn from these tests:

a If the weld is ground to the same thickness as the plate, the break will probably occur outside of the weld.

b Since all welds not ground flush broke outside of the weld, it is highly improbable that any double "V" welded piece of low-strength plate and properly reinforced will break in the weld.

c Bare-wire arc electric welding is not practical with a nickel-steel rod.

d Arc welds made in low-strength plate with proper electrodes and reinforced will always break the plate under tensile test.

APPENDIX NO. 2

TESTS OF WELDED PRESSURE VESSELS

Further tests of actual pressure vessels were later conducted to determine whether theories were borne out in practice. Six tanks were tested, of which four were made of firebox steel showing on chemical analyses of ladle tests to have the following composition: Carbon 0.12 per cent;

---

[1] A.S.T.M. Specifications 1921, p. 230.

manganese 0.38 per cent; phosphorus 0.012-0.015 per cent, and sulphur 0.028-0.035 per cent.

Tensile tests at the mill gave the following results:

	Longitudinal	Transverse
Tensile strength, lb. per sq. in	48,100–49,260	52,700
Yield point, lb. per sq. in	36,900–36,200	37,000
Elongation in 8 in., per cent	31–30	30

These four tanks were welded with $^1/_8$-in. diam. nickel-steel wire of the following composition: Carbon 0.21 per cent; manganese 0.60 per cent; phosphorus 0.025 per cent; sulphur 0.023 per cent and nickel 3.20 per cent. A No. 8 D-B tip, having a mixing chamber 0.098 in. diam., and the flame adjusted to suit the idea of the welder was used. A 90-deg. double "V" was used for the longitudinal seam, which was made with a cutting torch, and the scale carefully removed as much as possible with a chisel and wire brush. While the thin scale could not be taken off, all the large particles were removed. The head seams were 90-deg. single "V," made and cleaned in the same way.

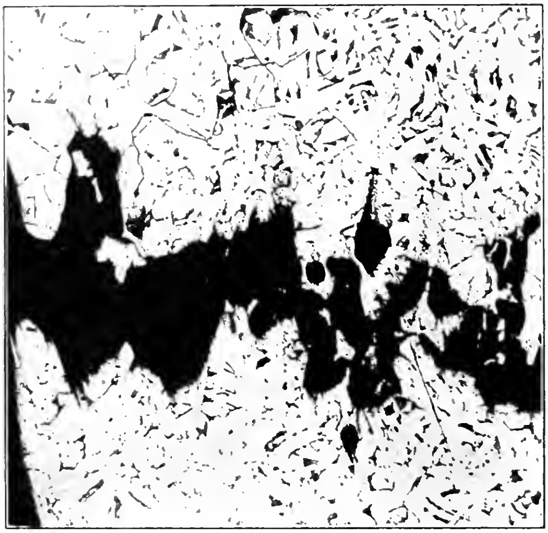

Fig. 4 Crack of Specimen B Opened by Strain. Originally of Same Character as Network at Right Which Outlines the γ Grains. Etched With Picric Acid; Magnification 100

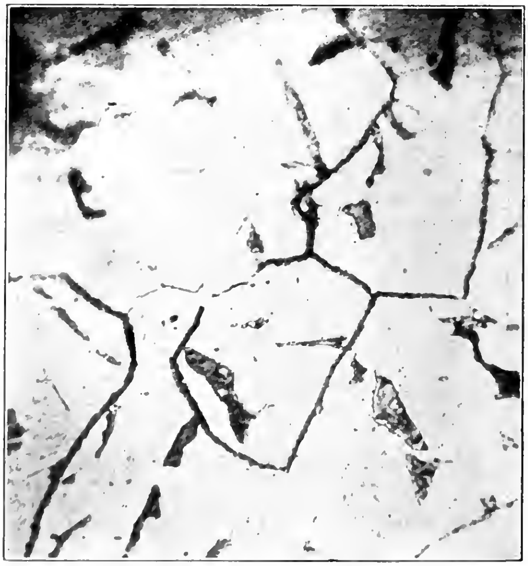

Fig. 5 Specimen Shown in Fig. 4 at Higher Magnification. Films of Oxide at γ Grain Boundaries are Very Clear and α Grains Can be Seen With Pearlite Lying at Outer Edges; Magnification 430

It was thought desirable to get some information about the shrinkage of the welds, so tram marks were made at different places along the seams on the outside of the shell, after the first side of the longitudinal seam was welded, with a tram 5 per cent long, so that the marks were about equidistant from the center of the weld. The same tram was used on the head seams after the heads were tacked in place, and before welding. The circumference of the tank was measured with a steel tape just inside each head seam, and at 3 other places, equally spaced, between the first two.

There were five welders used at different times on the work, which was done at the Rochester Welding Works. Their records bearing on their ability for the work, are as follows:

Fig. 6 Magnification of Portion of Fig. 5, Showing Details More Clearly; Magnification 1200

Fig. 7 Bottom End of Crack in Weld, Extending Through Cementite Which the Crack Appears to Have Split. Etched With Picric Acid; Magnification 1200

A Six years' experience. All-around job welder. Had welded heavier steel plate but very few pressure vessels.

B and *D* Four years' experience. All-around job welder. Had never welded plate as heavy, and never welded pressure vessels.

C Six years' experience. Good job welder, and had welded many pressure vessels up to $^3/_8$-in. plate thickness, but never thicker.

E Four years' experience in pressure-vessel welding but never in over $^3/_8$-in. plate.

These records show that none of these men could be called experienced on the job at hand.

In all the tanks, records of time and welding rod used were taken, but are not given because of the great variation in the fitting up, so that comparisons of the welders based on these figures would be unfair.

Only three of the tanks were tested because the pump was not of sufficient capacity to burst them in any reasonable time, although it was good for 2500 lb. pressure. It is hoped that a larger-capacity pump will be obtained soon and the test finished.

Tank No. 1 longitudinal seam was welded by A and *B*. The seam fitted so badly that it had to be wedged against a 70-lb. rail, after clamping the ends together and to the rail, to straighten it, and even then *B*'s end did not line up well. No tacking was done, and the welding was begun inside at the center of the length, both welders working toward their ends, using the backward method. The seam was allowed to cool over night and the tram marks (Fig. 8) and measurements made as mentioned above. The same men welded the outside of the seam, again working backward, beginning again at the center at the same time, and working toward the ends. The measurements were taken again after the shell was cold.

Fig. 8 No. 1 Tank (Same as Nos. 2, 3 and 4) Set up for Test. Figures 1 to 5 Locate Tramming Points at Seam

The heads (Fig. 9) were then tacked in place, with tacks from 9 in. to 12 in. apart, leaving the bottom of the "V" $^1/_4$ in. open before tacking. The tacks were somewhat over 1 in. long. The tacking and welding were done by *C*, who used forward welding. After tacking, the tank was allowed to become cold, the tram marks applied, and the welding finished. When cold, the measurements were again taken.

The pipe connections for testing were of $^1/_2$-in. extra heavy pipe, and were threaded in place, and gas-welded inside. The one in the center of the head was badly located for the test, as will be seen later, but would have been perfectly safe in service. An additional set of tram marks was put on this tank at the points where the circumference was measured. They are shown in Fig. 14 and were for the purpose of getting the elongation at and near the weld, if possible. The marks were on 2-in. centers, and the total length between the outside ones at each point was 10 in. All the tram marks on the shell were really chordal distances, but the errors of reading them were doubtless more than those due to their being chords instead of arcs.

All marks were laid out with a tram or dividers, and a jeweler's glass used to read them with a scale graduated to hundredths of an inch. The steel-tape measurements were read to the closest thirty-second of an inch. The shell not being round, it was only possible to divide up the inequalities between it and the heads as well as could be done. After the welding was done, the shell at the longitudinal seam was 0.21 in. higher than the head at one end, and 0.25 in. at the other. Similar variations occurred in the other tanks.

Fig. 9 Head of Tanks Nos. 1 to 4, Showing Radius Before Testing

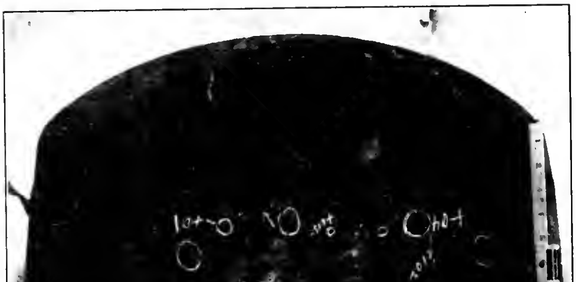

Fig. 12 Head of Tank No. 5 Bulged After Test. Original Radius 35 in., Final Radius 19 in.

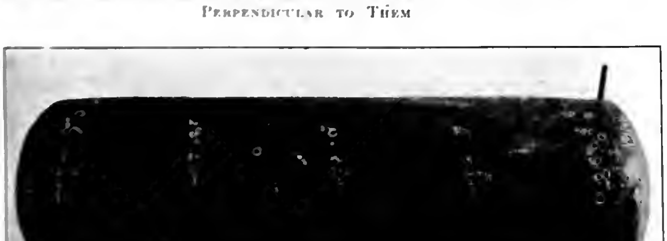

Fig. 13 One Seam of Tank No. 5 After Testing to 1900 lb. Nipple at Left Tapped in and Arc-Welded, and One at Right Tapped in and Gas-Welded Inside. Note Distortion of Ends

The testing was done with a motor-driven pump, which was found too small on the first test. A second one was built, and while it had sufficient strength, it did not have enough capacity to burst the shell, which, with the heads, simply stretched, with very little effect on the welds. This was true throughout the tests.

In no case could the welds be injured beyond the formation of minute pinholes or cracks, which, while they helped to keep the pressure down, at no time gave any evidence of any general rupture. These small cracks did not appear in any case until a very high pressure had been reached, the lowest being 1350 lb. This pinhole was stopped with one blow of a center punch, and did not appear again until the pressure reached 2100 lb. This means a fiber stress of about 31,000 lb. when the pinhole appeared, and of about 48,000 lb. when it showed up the second time. The fiber stress of 435 lb. working pressure is 10,000 lb.

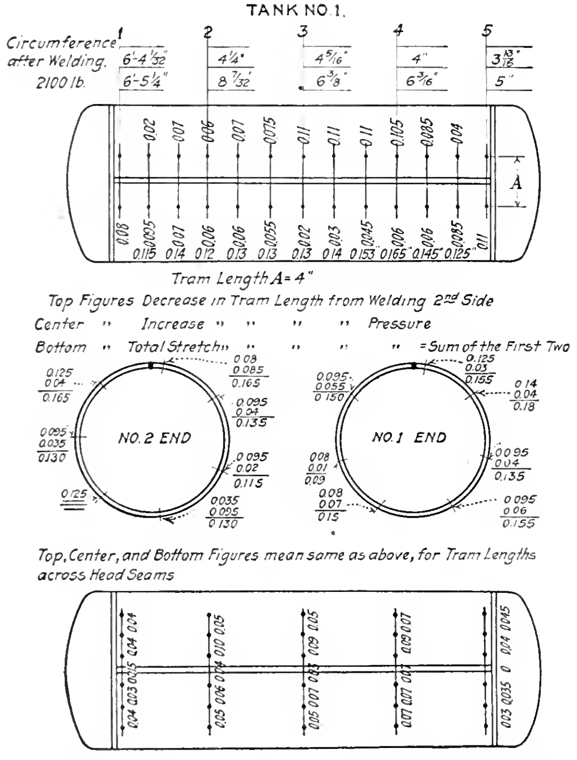

Fig. 14 Tram Measurements of Tank No. 1

The details of the test are as follows: The pressure was raised to 800 lb. and the seams then struck good swinging blows with an 8-lb. sledge. The pressure fell to 750. The pressure was increased, and at 1150 lb. Luders' lines appeared in the scale on the knuckle of the head, as shown in Fig. 10. At 1450 lb. a few drops of water appeared at the pipe nipple in the center of the head, but this leak stopped at 1500 lb. The yield point of the tank was very clear at 1500 lb., at which point the pressure was steady for a long time, while the heads could be seen stretching. The shell also took a slight permanent set, as will be seen from the following tabulation.

Circum. in.	Before test	At 400 lb.	At 800 lb.	At 1200 lb.	At 1500 lb.	At 1500 lb.[1]	After test	After 2150 lb.	Total stretch
1	76 1/32	76 1/16	76 1/8	76 1/8	76 1/4	76 5/16	76 1/4	77 1/4	1 7/32

---

[1] After prolonged application of this pressure.
[2] Flat spot in this vicinity had straightened out.

1500 lb. corresponds to a fiber stress of about 33,000 lb., as close as could be expected to the tests of the plate.

The pressure was raised very slowly to 1750 lb., at which the pump broke down and the test was stopped for the time being. The pipe nipple in the center of the head was removed and placed in the shell about 4 in. from the head seam, because the bulging of the head had opened the thread in the sheet away from that on the nipple. It was tapped into the shell, and a heavy boss electrically welded around it. There was no further trouble with it. Nor was there any leak at the other nipple, which was threaded in flange of the head and gas-welded inside before the head was welded to the shell.

A further test was made with a new pump, the pressure being raised to 2150 lb., without any leaks. The tank was continually stretching (Fig. 11) and at this pressure a small crack appeared in the longitudinal seam 18 in. from one end, and a very small pinhole in the head seam 12 in. from longitudinal seam. On account of these leaks the pressure dropped to 2100 lb., and the test was stopped. 2150 lb. corresponds to a fiber stress of about 49,500 lb. very close to the ultimate strength. The tram measurements are all given in Fig. 14. The remaining two tanks, numbered 5 and 6, were made of two pieces of Armco iron requiring two longitudinal seams.

The pressure was carried up to 800 lb. and the sledge test applied with no sign of failure. At 500 lb. Luders' lines appeared on the heads, and on account of their long radius, they bulged rapidly, and it was difficult to detect the yield point of the shell. It was probably at about 1100 lb. There was an increase of 1/2 in. in circumference at the center at 1250 lb.

At 1750 lb. a small crack, due to a lap on the inside of the seam, appeared, and the pressure was released, the defective part cut out and welded up.

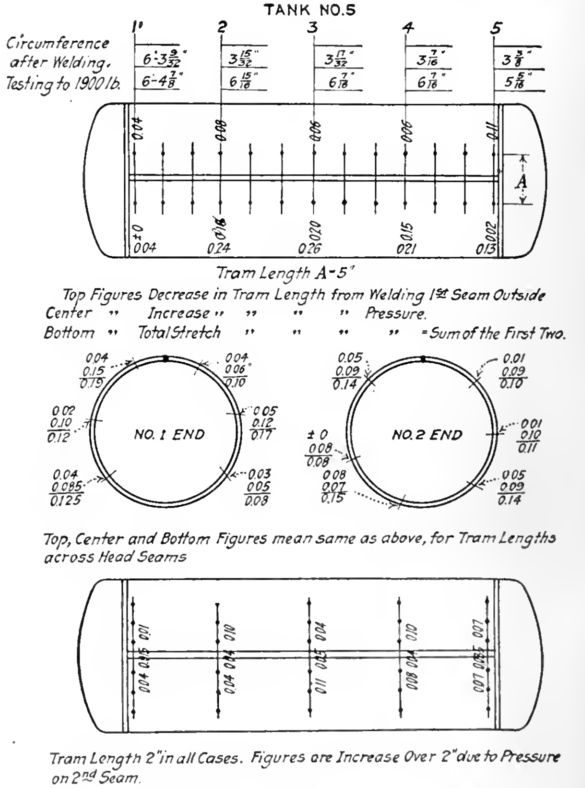

Fig. 15 Tram Measurements of Armco Tank No. 5

The pressure was increased to 1900 lb., when the weld in the center of the head, where the pipe-nipple hole had been welded up, gave way in a small crack. This, and the fact that the tank was stretching, made it impossible to continue the test. The fiber stress at 1900 lb. is about 43,800 lb., and as the tensile strength of Armco iron is about 44,000 lb., it is probable that the tank would eventually have given way at about this pressure. Figs. 12 and 13 show the results of the test.

It should be noticed that during the welding of these tanks almost everything was done that should not have been. The plates were badly rolled, they were out of line and flat, and fitted up badly. The "V's" were made with a cutting torch, and the welding was done with little regard to method and system. There was no preheating of the seams when the second side was welded, nor were the seams annealed or the shells rerolled to bring them more nearly to a truly circular shape. Also the heads did not fit the shells, as the latter were not circular. All of these were bad practices for a vessel designed for high-pressure work.

There were, however, four precautions taken. The plate was of low tensile strength, the wire of high tensile strength, the weld double "V," and the welding well done. So that in spite of the bad practices, the results are, in my judgment, very satisfactory, and resulted in safe pressure vessels. You may fairly ask if I would allow such bad practices in regular work, and I would reply without hesitation that I would not subscribe to any such conditions at all, because it is cheaper in a properly equipped shop to do the work right than to do it as these tanks were done. This is aside from any question of safety, or of good work, which are always paramount. How many of the precautions noted above should be taken in any case, depends on the conditions under which the tanks would be used, and so cannot be generally specified. It seems clear that the proposed method of using low-tensile-strength plate, high-strength welding wire, both of proper quality, with other precautions as may be needed, will result in uniformly safe work.

Using Exhaust Energy in Reciprocating Engines

BY J. STUMPF,[1] CHARLOTTENBURG, GERMANY, AND C. C. TRUMP,[2] SYRACUSE, N. Y.

There are a surprising number of cases where oil, gas or steam engines will show better economy than purchased power and electric motors, and this may be emphasized where the exhaust from steam engines is valuable for heating or process work. Up to now, reciprocating engines have suffered from losses due to incomplete expansion. There has been a compromise between such losses and mechanical ones connected with the use of very large cylinders. Oil engines, multiple-expansion and uniflow steam engines are coming to use high ratios of expansion, and these are doing much to reduce exhaust losses. Many advantages may be gained, however, if the energy remaining in the exhaust at release can be converted into kinetic energy, and from that into partial vacuum in the cylinder.

The theoretical problems are presented in this paper for discussion, and practical applications to either single-cylinder or multi-cylinder engines are suggested and illustrated.

WITH the rising prices for fuels in this country, anything which may result in fuel economy through turning more heat into useful work should be of interest.

The use of kinetic energy in long exhaust pipes has often been attempted in a practical way to the writers' knowledge in gas, gasoline and oil engines, especially of the two-stroke-cycle type, to improve the scavenging effect and increase the power output. Successful results were usually obtained more from a method of trial and error than from any attempt at design, or the use of nozzles, diffusers, etc., which might avoid losses and improve the effect.

Similar long pipes have been used on the suction side of air compressors, and on the discharge of pumps, to improve the volumetric efficiency. Whether conscious attempts have been made to produce such effects in ordinary steam engines, which usually have exhaust-valve passages too tortuous to avoid serious losses, will no doubt be brought out in discussion. It is probable that the studied application of suitable exhaust pipes with properly designed nozzles for gas and steam engines, especially those with piston-controlled exhaust ports, is new, for a United States patent has just been allowed on it.

In Fig. 1 is shown a conventional indicator card from a steam engine, with the loss due to incomplete expansion represented by the shaded area *D*. It will be noted that this area is large as compared with the small part of it due to opening the exhaust ports, or valves, considerably in advance of the end of the stroke. If the energy represented by *D*, plus that due to expansion to a lower final pressure such as the area *E*, can be converted into partial vacuum, it will obviously be transferred, or at least all of it but the losses, to the compression side of the card as useful work, represented by the area *F*. This would have the effect, evidently, of reducing the back pressure in the cylinder of the engine, and therefore the final compression pressure by a greater amount the more energy there is available at release.

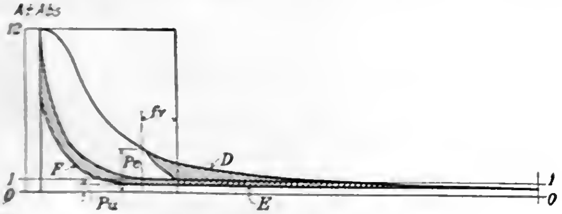

FIG. 1 CONVENTIONAL STEAM-ENGINE INDICATOR CARD SHOWING EXHAUST ENERGY

The several diagrams in Fig. 2 show how the loss due to incomplete expansion would increase with longer cut-off and higher release pressures. They also indicate how these losses may be turned into gains in useful work by reduction of back pressure and compression. The cards are all drawn for exhaust to atmospheric pressure and the pressure scale is in atmospheres. They indicate that any method of transferring energy into partial vacuum must be able to take care of variable loads. They do not indicate any relations between the time of exhaust opening and the velocities used in the exhaust pipes. These would have to be shown in a different kind of diagram, based on energy rather than pressures. The problem is somewhat similar to those met in ballistics, or in the design of Humphrey gas-pumping engines, in which kinetic energies of solid and elastic bodies have to be figured with respect to time and distance. The number of variables is so many, that graphic rather than numerical methods of computation are to be recommended.

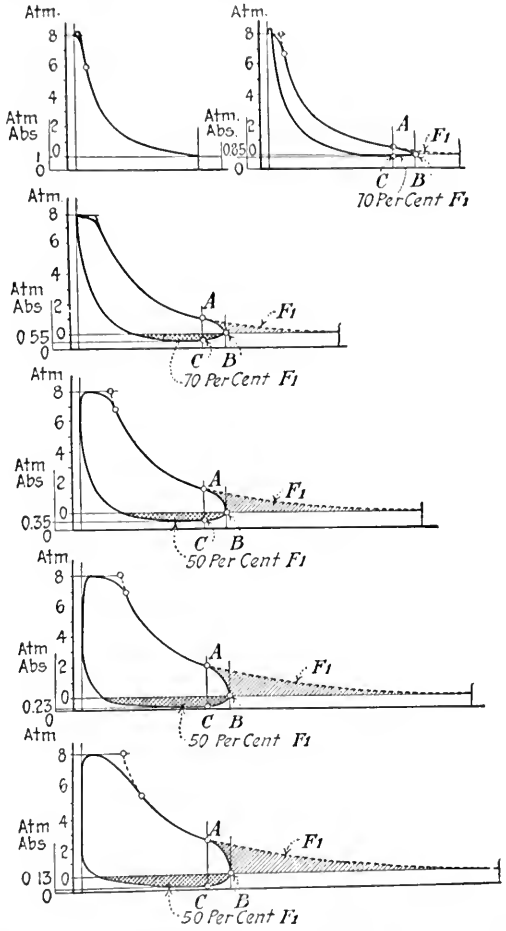

FIG. 2 CUT-OFF AND RELEASE PRESSURE EFFECTS ON INCOMPLETE EXPANSION LOSS

LONG EXHAUST PIPE IN PRACTICE

In order to give an idea of the practical application of a long exhaust pipe, for the above purpose, a uniflow steam cylinder with a number of exhaust nozzles and a long pipe is shown in Fig. 3. The nozzle in the cylinder is difficult to design for best efficiency because it is opened relatively slowly by the piston near the end of its stroke. The other end of the pipe should have some kind

---

Presented at the Spring Meeting, Atlanta, Ga., May 8 to 11, 1922, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. All papers are subject to revision.

of diffuser for reducing velocity energy to pressure energy, and this is also not easy to design. The action of the pipe itself would seem to depend upon the following several variable factors:

a The speed of the engine and number of exhaust puffs per minute.
b The variation of pressure at and after release at the cylinder.
c The variation of pressure at the other end of the pipe.
d The area of the nozzles and exhaust pipe.
e The length of the pipe.

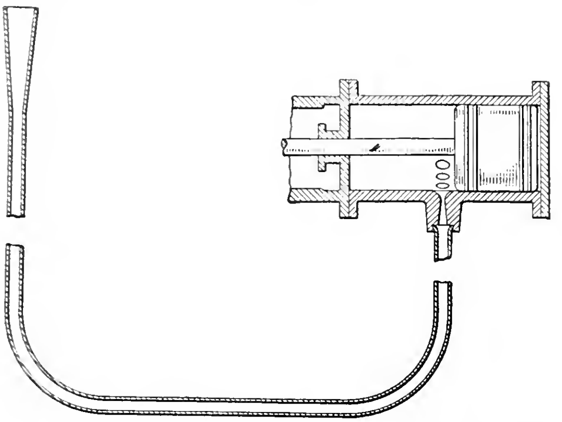

Fig. 3 Exhaust Nozzle and Long Pipe of Uniflow Steam Cylinder

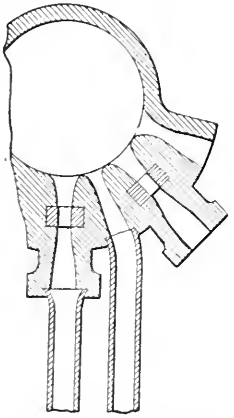

Fig. 4 Extra Nozzles and Exhaust Pipes for Regulation under Load Variation

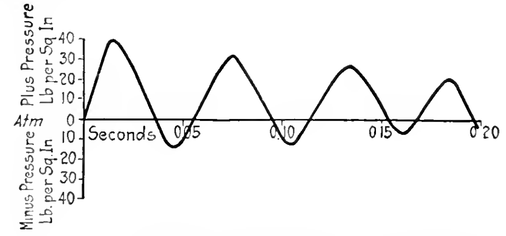

Fig. 5 Probable Vibration of Medium in Exhaust Pipe of Single-Cylinder Engine

f The duration of the exhaust period till closing of ports.
g The compression and expansion of the steam or gas itself.
h Heating due to friction.
i Cooling due to outside temperature conditions.

It may have been the experience of many, as it has been of the writers, that a pipe of this kind, subject to sudden puffs, will cause the steam or gas in it to pulsate. It is sometimes evident in cards taken with sensitive indicator springs. Its length and volume relations may be likened to those of an organ pipe. The difference may be pointed out that the pressure changes and velocities may be higher in this case, and vibrations much slower and longer are desirable than would be the case in the production of sound waves, which are to be avoided with exhaust pipes. It is evident, however, that the slower the speed of the engine the longer must be the pipe.

Provisions for Load Variation

For engines running at moderate and nearly constant speed, the pipe length may be fixed and the area designed to give the best suction effect at the most desirable load. Variation of load can be provided for, as shown in Fig. 4, with extra nozzles and exhaust pipes which may be thrown in or out of action by the engine-governing system. Another method would be to provide an exhaust pipe in the form of a coil, with valves which would change connection between cylinder nozzles and diffuser so as to vary the length of the pipe. This might be necessary with variable speed engines.

With single-cylinder engines the length of exhaust pipe necessary to produce the maximum suction effect may be too great for practical uses. As with a musical instrument, however, each vibration of the medium in the pipe may have its harmonic; or at least will be followed by other pulsations of reduced amplitude. If the second or third pulsation is caught at its lowest pressure as the exhaust ports close instead of the first, the pipe will have to be only one half or one third as long, respectively. The effect of friction losses and cooling may change the exact length, but the result may be in favor of the shorter pipe. Fig. 5 illustrates the kind of a vibration which may be expected.

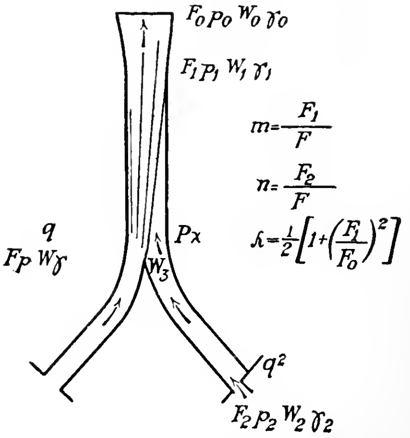

Fig. 6 Twin-Nozzle Design for High-Speed Multiple-Cylinder Engine

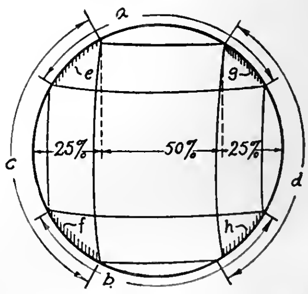

Fig. 7 Overlapping of Exhausts for Two-Cylinder Double-Acting Engine

Calculations for the proper length of exhaust pipes involve so many variables that it is probably easier to choose a reasonable size of pipe and arrange the cylinder with approximately the proper nozzles, then cut and try with different lengths of pipe and with a sensitive spring indicator on the engine until the best length is found. It may be interesting to suggest the use of graphical curves of pressure-volume, energy-volume, and energy-time as a means of arriving at the approximate design with which to start experiments.

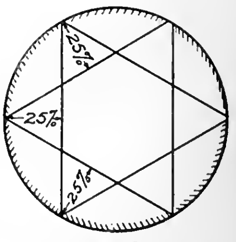

Fig. 8 Gain in Overlapping With Three-Cylinder Double-Acting Engine

Overlapping Exhausts

For multiple-cylinder engines, especially those which run at high speed, the periods of exhaust will overlap, and by proper design of nozzles one exhaust may be made to draw on the other. Such a twin-nozzle design is indicated in Fig. 6, which is that on which the work with a two-cylinder locomotive has been based. The overlapping of the exhausts for such a two-cylinder double-acting engine is shown in Fig. 7. The gain in overlapping with a three-cylinder, double-acting engine is shown in Fig. 8.

It is evident from these two diagrams that with four exhaust puffs per revolution, or less, it is necessary to take account of the

vibratory action of the exhaust pipe. Its length and volume and the cooling and friction loss must be fixed either by calculation or by experiment, or in combination. With six or more exhaust puffs per revolution the suction effect may be almost entirely produced by ejector nozzles, so paired as to coöperate and induce partial vacuum in each cylinder at the instant when the exhaust port is closed, at the beginning of compression. Even in this case it may be necessary to proportion the exhaust pipes, in length and volume, so that adverse vibrations may not be set up to spoil the vacuum.

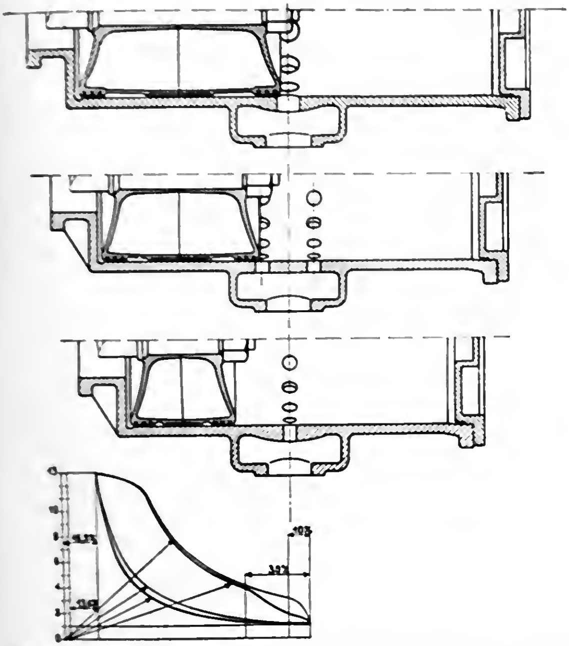

Fig. 9 Area Modification and Location Rearrangement to Shorten Piston and Cylinder of Double-Acting Engine

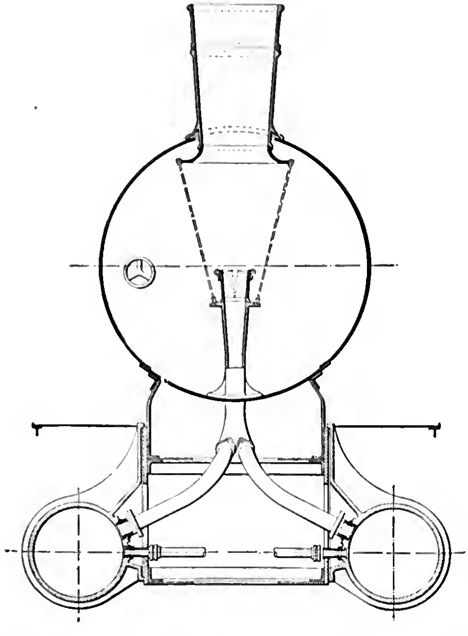

Fig. 10 Number of Exhaust Ports Reduced and Large-Diameter Exhaust Belt Dispensed With in Non-Condensing Engine

Single-acting engines of four cylinders and less will evidently require longer exhaust pipes than those of six cylinders and more. The higher speeds at which these engines are usually run will tend to reduce the necessary pipe length. All the benefits of the exhaust-ejector action accrue to single-acting engines, except that when the pistons control the exhaust ports they cannot be made shorter, as will be explained later, with respect to this advantage, in double-acting uniflow engines.

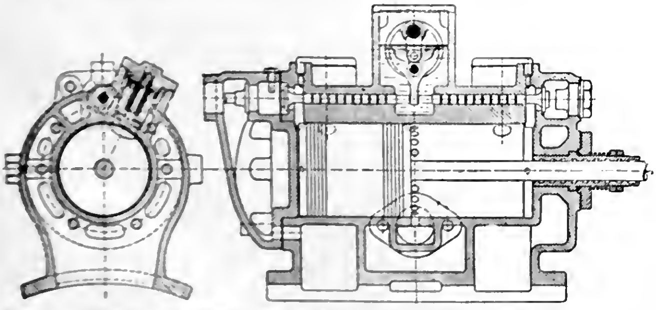

Fig. 11 Original Cylinder Design With Long Piston, Numerous Exhaust Ports, Large Exhaust Belt and Necessary Compression-Relief Valves

Ordinary counterflow steam engines with exhaust valves, or with a single valve for admission and exhaust, not only would be difficult to arrange with suitable nozzles to avoid eddy losses, but the exhaust period is usually made too long to be covered by the larger pulsations of the long pipe, or the ejector effect of other nozzles. A cylinder with exhaust ports, like a two-stroke-cycle gas engine or a uniflow steam engine, can be provided with almost unlimited exhaust port area and the exhaust period can be controlled—to be long for high speeds, or short for low speeds. The four diagrams in Fig. 9 show how the exhaust ports may be modified as to area, and rearranged as to location, so that, with a double-acting engine, both the piston and cylinder become shorter. For non-condensing work, such as in locomotives, automotive vehicles, and a large proportion of our stationary engines, the number of ports may be reduced to one, two or three, and the exhaust belt of large diameter dispensed with as shown in Fig. 10. The smaller nozzles in this illustration are provided for bleeding steam, after it has done useful work, for heating cars, or feedwater. Such nozzles may also be used for supplying steam for process work, or for heating, with a small part of the exhaust from stationary engines. The long exhaust pipe and ejector action may also be used to reduce the clearance volume required to control compression, or to dispense with exhaust valves, when it is desired to operate the engine with exhaust against back pressure higher than atmospheric, and use all the steam for heating or process work.

Comparison of Cylinder Designs

The practical advantages of reducing the exhaust orifices to two long slots are well illustrated by comparison between Figs. 11 and 12. Fig. 11 shows the original design of cylinder for a portable engine and boiler for farm or well-driller use. The long piston, large number of exhaust ports, large exhaust belt, and the necessity for compression-relief valves, are evident. In Fig. 12, however, the piston and cylinder have been shortened considerably, the piston over 25 per cent, and the cylinder nearly 20 per cent. The exhaust ports and belt have been reduced to two nozzles, and the cylinder support has been simplified and moved to one end only. Compression-relief valves have been dispensed with, except for small drain cocks for starting a cold engine. The long exhaust pipes are shown leading to the smokepipe, in Fig. 13. Experience with the locomotive has shown a more uniform draft is induced than was the case with the sudden puffs of the ordinary exhaust-pipe arrangement. The pipe which is shown leading out of the diffuser in the smokestack is evidently provided to take off steam for heating feedwater.

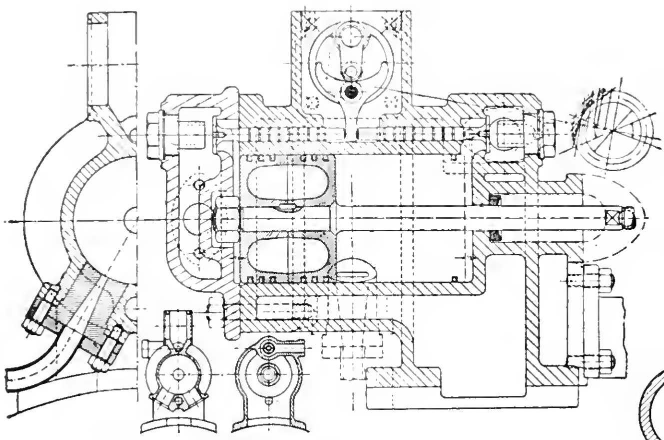

Fig. 12 New Design With Shorter Piston and Cylinder, Two Nozzles and No Compression Valves

Nozzle Arrangement

In multi-cylinder engines several different arrangements of exhaust pipes and nozzles suggest themselves. Perhaps the simplest is that often seen in gasoline-automobile-engine exhaust pipes, which may be called a series arrangement as shown in Fig. 14. This may have the disadvantage that the cylinders farthest apart should benefit by overlapping periods of exhaust, whereas the several nozzles between the end cylinders are likely to interfere with friction losses. Bringing a loop of exhaust pipe back behind the first nozzle, as shown dotted in the diagram, might improve this arrangement, if proper length is used.

Another disposition of nozzles is shown in Fig. 15. This may be called an arrangement in pairs, or in parallel. The pairs of cylinders which have the longest overlapping of exhaust, because of their crank-throw relations, should be connected to the same exhaust nozzles. The common discharge from these paired nozzles should then be connected in other pairs, finally to discharge through a common exhaust pipe and diffuser.

If it is desired to take off exhaust steam at a pressure above that of the atmosphere, the exhaust-pipe diffuser must be made part of a large receiver tank, from which a small pipe or pipes may lead steam to the heating system at nearly constant pressure. The volume of such a receiver must be large, or the changes of pressure in it will have too great a damping effect on the exhaust-pipe pulsations. It makes design by calculation still more difficult.

The practical application of long exhaust pipes, receivers, nozzles, etc., is by no means so difficult as their proper design. Experience with Humphrey pumping engines of all types and sizes has shown that the inertia effect of long pipes may be a decided detriment to efficiency in some cases, but may be turned to decided advantage if properly utilized and controlled. One of the writers has seen the capacity of these internal-combustion engines improved 50 per cent by simply changing the length of exhaust pipe. Fortunately the graphical methods of design developed for Humphrey pumping engines may be easily adapted to new uses. Ways must be found to take account of more variable factors (nine or ten in this case); but that is easier by graphical than by any other method. It may, however, take some time and experimental work to determine the practical coefficients.

Long exhaust pipes and proper nozzles, however, do provide a means of controlling compression, which in a uniflow engine serves to improve thermal conditions, as well as mechanical cushioning, for which it is mostly used in ordinary steam engines. They avoid large clearances in non-condensing engines, or the alternative of mechanically operated exhaust valves, which the condensing uniflow engine has already dispensed with. The writers of this paper will welcome a broad discussion of the subject.

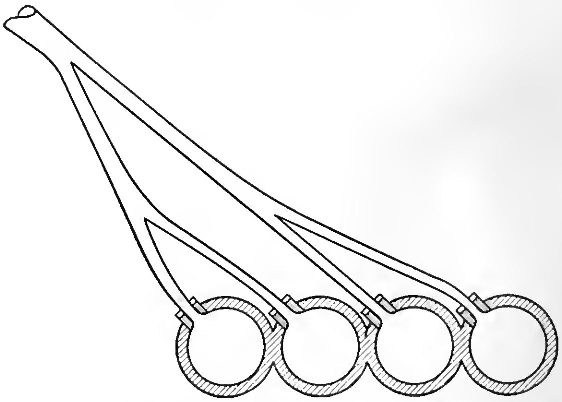

Fig. 15 Pair or Parallel Arrangement of Nozzles in Multi-Cylinder Engine

In a letter to the *Iron Age* (May 11, 1922, p. 1299), G. H. Benjamin cites several decisions of the Federal Courts to the effect that an employer has no right to a patent for an invention made by an employee in the absence of an express contract or agreement for the specific employment to make an invention.

The general principle employed is that if an employer made an invention after he entered the service and the invention was not distinctly specified and included within the terms of contract, the contract does not extend to such invention.

The rule followed by many corporations in making contracts with employees is to specify so much for their services in the line of their specialty and so much for any inventions that they make during the time of their employment. If such special compensation was not specified the employer has no right to the invention of the employee.

Unless the invention has been distinctly specified in the contract of employment it is accepted that the contract does not extend to the invention, as the invention was not "in being" or contemplated at the time the contract was signed and therefore was not within the terms of the contract or covered by the compensation.

Burning Bituminous Coal on Stokers

Importance of Keeping a Bituminous-Coal Fire Agitated—Coal Analyses and the Danger of a Low-Fusing Ash—Typical Stoker Installations and the Best Methods of Operating Them

AT THE Joint Fuel Conference held by the New Haven Branch of the Connecticut Section of the A.S.M.E., the New Haven Chamber of Commerce, and local sections of other engineering societies on November 14, 1921, of the five papers presented three bore on stoker operation with soft coal, namely: two entitled Burning Bituminous Coal on Taylor Stokers, by G. E. Wood, of the Connecticut Company, New Haven, and O. J. Richmond, of the United Illuminating Company, Bridgeport, Conn.; and Burning Bituminous Coal on Type E Stokers, by R. A. Sanders, of the Seamless Rubber Company, New Haven.

Among other things these papers point out those items of a coal analysis that, if not held within proper limits, will cause trouble. When operating at above 150 per cent of rated capacity it is most important that the coal should have a "high-fusing" ash; that is, the ash should not melt under 2400 deg. fahr. Where this precaution has not been observed the operation of the stoker has been seriously interfered with. Valuable hints on obtaining the best results from these two types of stokers are also included.

BURNING BITUMINOUS COAL ON TAYLOR STOKERS

By G. E. WOOD,[1] NEW HAVEN, CONN.

THE Taylor stoker is representative of the underfeed type which introduces the fuel into the furnace from beneath the fuel bed. The fuel is forced in by the action of rams and in this manner the whole fuel bed is kept agitated. As we all know, this is of vital importance to the successful combustion of bituminous coal, for in the initial stages of combustion this coal tends to soften, coke and run together. If it is left in a quiescent state it will solidify into a homogeneous mass that is highly resistant to the passage of air at ordinary pressures. It is due, therefore, to this agitating action that the underfeed stoker has been successful.

In operating a Taylor stoker it is fundamentally important to maintain a uniform speed so as to free the grates of the ash as it is formed. This condition willl insure clean fires. If the ash is allowed to accumulate, it is forced up into the fire, the inevitable result being clinker formation. In addition to uniform speed, care should be exercised in operating the lower rams and the extension grates. The long stroke should be used on the former to prevent the fire from piling too high and falling over on to the dump plates—the latter just before dumping to break up clinker, and after dumping to cover the grates and prevent air leakage. The thickness of fire depends on the load, but the contour should be maintained standard at all loads, i.e., high on the upper portion of the grates and sloping gradually off to the dump plates.

Under normal conditions it has been found that good results are obtained by leaving the air damper to the extension grates open at all times. The speed of the stoker and the plenum in the wind box best suited for various ratings are approximately as follows:

Rating, per cent	Stoker speed, time per rev.	Wind-box pressure, in. of water
100	3 min. 54 sec.	1.0
150	2 min. 38 sec.	2.25
200	2 min. 5 sec.	2.90
250	1 min. 35 sec.	3.80

These figures do not hold in all cases and should be checked by flue-gas analyses. They are of value, however, in that they give a close approximation of what the conditions should be.

The difference in the performance of coal of different analyses at an average rating of 150 per cent may be seen from Table 1 in the next column.

In the case of Sample A the speed of the stoker and the air pressure agree closely with the figures previously given, the speed being somewhat higher and the air pressure a trifle lower. No trouble was experienced from moderate clinker formations because they were small. Under 250 per cent of rating the results were equally satisfactory.

With Sample B, during the test considerable trouble was encountered from large clinkers forming on the tuyeres and freezing on the side walls, extension grates and bridge wall. This condition accounts for the long time required to dump. Holes in the fire were numerous on account of the clinker pulling the coke down. These holes were filled as best they could be by using the long stroke for the lower part of the grate and a hoe for the upper sections.

At 250 per cent of rating, clinkers formed so rapidly that they could not be kept moving. The shear pins let go and the stoker was put out of commission after $1^1/_2$ hours' run. At the end of the first hour it was necessary to dump and it required the combined efforts of 3 men for 45 minutes to accomplish this process. The coal was practically useless under forced firing.

TABLE 1 PERFORMANCE OF TWO DIFFERENT COALS AT AN AVERAGE RATING OF 150 PER CENT

	Sample A	Sample B
Moisture, per cent	4.8	3.4
Volatile matter, per cent	22.1	32.6
Fixed carbon, per cent	66.6	53.8
Ash, per cent	6.5	10.2
B.t.u. per lb. as fired	13,774.0	13,103.0
Sulphur, per cent	under 1	2.25
Rate of combustion, lb. per hr. per sq. ft. of grate	33.0	34.0
Refuse, per cent	9.5	16.3
Combustible in refuse, per cent	30.0	38.0
CO_1, first pass	12.9	13.8
CO_2, flue	11.8	12.8
Average speed of stoker, time per rev.	2 min. 13 sec.	2 min. 36 sec.
Average pressure in wind box, in. water	2.46	2.20
Time between dumps	3 hr.	2 hr.
Time required to dump	2 min.	20 min.
Combined efficiency, per cent	75.8	74.8

From the two examples cited the vastly different results obtained with coals varying but 4 per cent in ash, 10 per cent in volatile matter and $1^3/_4$ per cent in sulphur are evident. The ratio of refuse to coal fired increased, and the percentage of combustible in the refuse increased on account of the clinker formation. Nothing could be done to prevent this formation of clinker, but the "freezing" to the side and bridge walls can be alleviated. To accomplish this, many operators have employed the form of furnace construction which allows the air from the wind box to circulate through the setting walls so as to maintain a flow of air between the walls and the fire. Others use a steam jet instead of air, and in some instances both are used. Either method is effective and greatly facilitates the burning of badly clinkering coals.

Not only does the proportion of ash have a direct bearing on economy, but the temperature at which the ash fuses is an important factor. Tests have been made that show that the efficiency follows the ash-fusing temperature. From these tests it has been concluded that all ash fusing below 2400 deg. fahr. should be classed as low-fusing, and all above as high-fusing.

While it is possible to burn a coal with low-fusing ash under normal loads, it is difficult if not impossible to do so under heavy overloads. The ash invariably melts and runs into the air spaces in the tuyeres, shutting off the air supply. It also bends a crank or breaks a bearing bracket if the shear pin fails to shear. The only solution is to burn the fire down, take the boiler out of service, and send a man into the furnace to break the clinker out.

From these observations the following conclusions may be deduced:

a A good grade of coal with low ash, volatile and sulphur content can be burned efficiently with no trouble and moderate loss of combustible in the refuse;

b As the ash, sulphur and volatile content increase, trouble occurs and the avoidable loss of combustile in the refuse increases.

BURNING BITUMINOUS COAL ON TAYLOR STOKERS

By O. J. RICHMOND,[1] BRIDGEPORT, CONN.

THE Taylor stoker utilizes the gas-producer principle. Green coal is fed by the rams to the lower strata of the fuel bed and is gradually pushed up toward the upper layer and coked, at this time giving off most of its volatile elements which have to pass through the incandescent zone. The coal works upward still farther and it becomes incandescent by the time it reaches the top layer. The grates are sloping, and as the coal gradually burns to ash, it works downward toward the refuse dump where it is discharged by the dumping process to the ashpit. These stokers are very flexible and well adapted to sudden overloads, since in a very few minutes they can run a fire from a banked to an overload condition. They employ forced draft at normal rating, from $1^1/_2$ to 2 in. of air pressure being used when 30 to 40 lb. of coal are burned per hour per sq. ft. of grate; 3 in. to 4 in. is used for higher ratings, and it is possible to burn 60 to 80 lb. per sq. ft. per hour for short peaks.

The plant whose operation the author has been asked to discuss consists of 18 B. & W. boilers each rated at 600 hp. by the builders. They have 294 4-in. tubes 18 ft. long and 6000 sq. ft. of heating surface. The pressure carried is 200 lb. gage. The stokers are of the Taylor type, 7 retorts wide, $8^1/_2$ ft. deep, and hand-dumped. The grate area is 95 sq. ft. Distance from stoker to lower row of tubes is 7 ft.

Draft is supplied by nine American Blower Co. fans of the high-speed type, all driven by Terry turbines. These blowers discharge into a common main air duct for all boilers. The air is carried from this main duct by small steel ducts to the stoker forced-draft damper. Regulation of blower is by steam pressure acting through an individual Mason regulator for each fan set.

The coal used is R.O.M. bituminous, a typical analysis of it being: moisture, 1.58 per cent; volatile, 21.40 per cent; fixed carbon, 71.37 per cent; ash, 5.65 per cent; B.t.u., 14,464 per lb. dry; sulphur, 1.06 per cent.

Coal is run from the bunker by gravity to the electrically driven weigh lorry cars. After being weighed it is fed directly through the lorry car chute to the stoker hopper.

The boilers are run from 125 per cent to 150 per cent of rating. This policy was determined by running different numbers of boilers for given loads on the station. It was found by trial that when the boilers were run above 140 to 150 per cent the efficiency dropped off. The apparatus which automatically speeds up the stoker with any increase of air pressure, and thereby tends to keep the proportion of air and coal constant, does not work satisfactorily. While it is admitted that for any given set of conditions, kind of fuel, construction of furnace and method of stoking, a definite volume of air will consume a definite weight of fuel, in practice this does not hold because the fuel varies. In the new Steel Point Station the regulation has been modified by the addition of the Keelhaltz regulator, manufactured by the A. E. Co., and every assurance has been given that this device will regulate satisfactorily even with variation of fuel.

Standard practice is to maintain as nearly constant an air pressure as possible for a given load. From 2 in. to $2^1/_2$ in. is used under fires and from 0.1 to 0.2 in. suction or negative draft over them. This suction over fires is kept at that point by the so-called balanced-draft regulators. These have been found to work very nicely with a minimum of upkeep, and help materially in keeping stack losses down. Fires are maintained from 20 in. to 30 in. thick, depending on the coal. For all ordinary coals 26 in. to 30 in. of fire and $2^1/_2$ in. air blast are used. With inferior grades it has been found that the Taylor stoker handles large clinkers readily, and they work down to the dump with little trouble. The clinker that makes trouble is the thin, soft, pasty variety that with some coals runs at times like hot tar on to grates and tuyeres, and even into tuyere air inlets, getting a firm grip and shutting off the air supply in such a way as to result in burned tuyeres. The only way to handle such coal is to run thinner fires and more air in proportion to coal burned, naturally at the expense of efficiency, but keeping the plant running.

Fires are banked by shutting off the air supply and pumping coal enough in to keep the fire away from the grates. Stokers with banked fires are turned over a few times every 2 to 4 hours to prevent so-called "freezing." This occurs when the coal cokes so hard in the bank that it is difficult for the stoker rams to break it up. Every other night boilers are cleaned of what clinkers are adhering to the side walls which are steel mixture blocks.

BURNING BITUMINOUS COAL ON TYPE E STOKERS

By R. A. SANDERS,[1] NEW HAVEN, CONN.

AT THE Seamless Rubber Company, steam is produced for heating and curing in the production of rubber goods and for operating boiler auxiliaries. Power to drive the machinery is purchased from the United Illuminating Co.

The boiler plant consists of four Babcock & Wilcox water-tube boilers of 393 rated hp. each, equipped with Foster superheaters each with a guaranteed performance of heating 19,788 lb. of steam from 150 lb. gage pressure and 1 per cent of water to 466 deg. fahr. or 100 deg. superheat. Feedwater is heated in a Cochrane open feedwater heater, equipped with a V-notch recording, indicating and integrating meter and forced into the boilers by two three-stage turbine-driven pumps. The output of the boilers is measured by G. E. indicating steam-flow meters on each boiler and an integrating meter on the main steam line to the factory. Flue-gas temperature is measured by a Brown recording thermometer on each boiler showing the temperature at the damper. Another Brown meter is used to record the temperature of the feedwater as it leaves the pumps.

Two No. $6^1/_2$ Buffalo conoidal fans, each capable of delivering 40,000 cu. ft. of air per min. against 6 in. water static pressure, furnish the forced draft necessary to operate the boilers. With maximum delivery the speed is 1260 r.p.m. Under the usual operating conditions, the pressure under the fire being 3 in., the speed is about 1030 r.p.m., the horse power $24^1/_2$, and one fan serves two boilers at 100 per cent rating.

Each boiler is equipped with a type E single-retort stoker made by the Combustion Engineering Co. These stokers are guaranteed to hold the steam pressure within 5 lb. of the specified pressure when the boilers are operated up to 200 per cent of normal rating and to give a combined boiler and furnace efficiency of 75 per cent when the boilers are operated between 100 per cent and 200 per cent of normal rating, the draft in the furnace not to exceed 0.15 in. at 200 per cent rating and to operate under conditions specified and at the same time conform to the smoke laws or regulations of the city of New Haven.

Bituminous run of mine coal is received in hopper-bottom cars and dumped directly into a truck hopper, passing then to a crusher, the capacity of which is 20 tons per hour, which reduces it from a maximum of 10-in. cubes to 2-in., the average being 1-in. A 15-hp. squirrel cage motor provided with remote control operates the coal crusher.

It is then carried by a bucket conveyor, driven by a $7^1/_2$-hp. induction motor, also remote-controlled, into the overhead bin in the power house. This bin holds about 120 tons and is provided with a belt conveyor which distributes the coal the length of the bin as required.

Four automatic recording coal scales are provided, which weigh the coal as it is fed into the spouts feeding the stoker hoppers. The motors driving the feeding mechanism of the scales are controlled from the boiler-room floor.

Motors driving the crushing, elevating, and distributing machinery are controlled from several points, as a precaution against injury to the installation.

Actual daily evaporation from feedwater which averages 210 deg. to 130 lb. gage, averages about 10.8 lb. of water per lb. of coal burned. No figures are available as to the amount of superheat in the steam, but it is estimated that it is about 50 deg.

Weaving Machinery

Weaving Styles and Kinds of Fabrics Produced—Details of Methods Employed—Functions of Special Machine Devices—Different Types of Looms

BY L. B. JENCKES,[1] WORCESTER, MASS.

THE process of weaving consists of interlacing two or more series of fibrous materials or threads at right angles or nearly so, so that they will form a fabric. The threads running lengthwise of the cloth are called the warp or "woof," and those running crosswise of the goods are called the weft or filling.

Weaving does not include all fabrics and must be distinguished from those which are felted or plaited, and from netted lace fabric and knitted goods.

A felted fabric is made by bringing masses of loose fibers such as wool or hair together under the influence of heat, pressure, moisture and friction, under which conditions they become firmly interlaced in every direction and form a hard and serviceable fabric.

Plaited fabrics are composed of one set of threads interlaced, but not at right angles. A flat shoelace is an example of plaited fabric.

In netted goods the threads are held in place by knots where they cross each other.

Knitted fabrics are composed of one or more threads held together by loops, making a very elastic fabric, similar to the common Jersey cloth.

Laces are made by passing one set of threads around small groups of threads of a second set instead of passing them from side to side.

With these fabrics we have nothing to do as we are to consider only weaving.

MODERN PROCESS OF WEAVING

The process of weaving in a very general way is this. The warps are wound in a parallel manner on a roll or beam at the back of the loom, the roll being carried in gudgeons and held by friction from allowing the warp to run off too easily. The warp usually passes over two rods called "lease rods" and then through an eye in the center of a wire or cord called a "heddle." The heddles are attached at the top and bottom to a number of harness frames or "healds," being attached to different frames according to the pattern to be woven. Thus the threads can be separated into two planes or sheds forming an opening between, which allows a shuttle carrying the filling or weft to be passed between them. After the weft is passed a batten or lay carrying a reed is drawn forward, forcing or beating up a strand of filling against the next preceding one. The warp threads are then changed, those in the upper plane passing to the lower one and others taking their place in the upper shed. This forms one cycle and places one thread of filling or one pick in the cloth. The point at which the cloth is formed is called the fell. The edges where the filling returns and repasses into the cloth is called the selvage. After the cloth is formed it is drawn forward and wound onto a roll by the take-up.

ANCIENT ART

The art of weaving is a very ancient one. Very soon after the first inhabitants appeared on the earth they tired of using skins alone, and by interlacing fibrous material, grasses, strips of skin, etc., began to form woven fabrics. The spinning or twisting of fibers into threads was soon discovered and gave great impetus to the art of weaving. Colored threads and material of various lusters and characters were used; soft warm material for the cold climates, and lighter for warm ones, until now every kind of material that is known is woven into a fabric—wool, hair, flax, paper, grasses, metal and almost everything else. Woven fabrics are very largely used, not only for clothing but for manufacturing equipment such as belts, packings, conveying belts, filter cloths, and other products.

The ancient tribes of the East probably contrived the first loom very early in the history of the world. They hung a beam or stick in a tree or from some overhead support and from it suspended the series of warp threads. These warp threads were hung to another beam or log at the lower end. These warp threads were separated into two planes by means of a flat swordlike implement, the sword being given a quarter turn to separate the warps so that a shuttle carrying the weft could be passed. The implement was then drawn downward sharply, beating the line of filling against the preceding one, and the cloth was formed. The sword was then withdrawn and reinserted, separating the warp into different sets of threads, and the process was repeated. Probably in the first weaving, reeds and grass were largely used for the filling. This process was also used by the Egyptians and Greeks. The ancient tribes of India are believed to have laid the warp horizontally and fastened it to a beam, and used a crude heddle frame and heddles suspended from overhead, separating the warp into the two sheds, and also to have had a batten or lay swung from overhead to beat up the cloth. After passing the shuttle a few times back and forth the lay or batten was drawn forward and the cloth beaten into place.

The Chinese were the first to weave to any great extent. They are said to have cultivated silk long before the Christian era, and were weaving intricate designs such as dragons, flowers, fruits and other patterns which would be elaborate even today, and this was 200 B.C. While they were doing this the Egyptians and other races of the Near East were only just learning about silk—their experience in shuttle weaving having been limited to spun wool and flax—the ornamentation being almost entirely done by embroidering or darning. Far the greater part of the material woven was plain.

So far nothing has been said about the variation of color in the cloth. Cloth is colored in various ways. It may be dyed in the piece after it is woven, in which case it must all be practically the same color. The yarn may be dyed before it is woven, and woven in patterns, in which case the patterns are nearly all geometric in style. A pattern may be printed on the goods after they are woven, in which case it may be as elaborate as desired. The warp threads may be printed with a pattern before they are woven, that is, each thread may be of various colors throughout its length so that when woven the cloth will present a pattern.

STYLES OF WEAVING

Almost all the different styles of weaving or interlacing of threads may be divided into four classes: First, single cloth—that is, a cloth having one set of warp threads and one set of filling threads only; second, backed or compound cloth having more than one set of warp threads or more than one set of filling threads; third, pile fabric in which a part of the threads are caused to stand on end above the body of the cloth; and fourth, leno cloth where the warp threads are crossed or twisted.

KINDS OF FABRICS WOVEN

Of the single cloths the simplest is that in which the warp threads are divided into two sets only, one-half of the threads being passed through each of two sets of heddles, each set being carried on one heddle frame so that one-half of the warp is in the upper plane each time. Consequently the warp and filling pass over and under each other alternately. If the warp and filling are of equal size the cloth is perfectly plain and square, and it can hardly be told which is the warp and which is the filling. By varying the comparative size of the warp and filling a ribbed effect is produced. If the filling is the largest the ribs run across the goods, and if the warp is the largest the ribs run lengthwise of the goods. Very much of the greater part of all the cloth which is used is formed in this way. It makes muslin, sheeting, and all such common cloths. When colored and sized it makes cambric. When printed with pattern after being woven it forms calico. Gingham is made in

---

[1] Engineer, Compton & Knowles Loom Works. Mem. Am.Soc.M.E.

Abstract of paper presented at the Spring Meeting, Atlanta, Ga., May 8 to 11, 1922, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. All papers are subject to revision.

this way by using warp and filling of various colors. Canvas and duck are of this construction. Taffeta, pongee, and grosgrain silk are all of the same weave as well as the much-used crepe. In crepe the filling is of two kinds, causing the cloth to crinkle. Much of the cloth for men's and women's wear and other purposes is of this formation.

We now come to twill goods. In these the warp is divided into three or more sets and only one-third or one-quarter is brought into the upper shed or on to the face of the goods each pick. All these goods will show a diagonal rib or line on the face, the breadth of the line varying according to the order in which the harness is raised. With warp and filling of the same size the lines will make an angle of 45 deg. with the cloth. If the warp is larger than the filling the angle will be less, and if the filling is larger than the warp it will be greater. By varying the order in which the harness is raised the ribs can be broken and form broken lines, zigzags, diamonds or squares, making a variety of geometric patterns.

Another large class of goods is formed by the satins and sateens. The object in these goods is to present a smooth, patternless surface, and it is accomplished by using a great many very fine threads to form the face of the goods either in the warp or in the filling. For satin the warp is of the fine threads, and forms the face, while for sateen the filling is used for this purpose. In weaving satin from five to twelve harnesses are used, each filling thread appearing on the surface only once in five to twelve picks for about one pick only; the warp being so fine and so close together that the filling pick cannot be detected. In sateen the warp and filling are reversed. The combination of satin and sateen is greatly used in forming the pattern of table damask.

These weaves form almost all the plain cloth, and it is by using a combination of these that an endless variety of cloths is provided, stripes, checks, etc., of various kinds of weaves being combined in the same piece of goods.

It often becomes desirable, however, either for warmth or softness to add weight to a piece of goods without interfering with the pattern, and this is accomplished by using two sets of filling and one set of warp threads, or by using two sets of warp threads and one set of filling. The use of two sets of filling threads usually makes a soft piece of goods as the filling yarn is apt to be of soft character, but it is also the most expensive since it is slow to weave. The face of the goods is woven as before and the face yarn is always kept on the face of the goods, the backing yarn being under it and attached to it by passing just sufficient threads under each backing thread to hold it firmly in place. Sometimes the face and backing yarn are caused to exchange places, forming a pattern on the face, and the reverse of the pattern on the back. This is called reversible goods.

Two complete cloths may be woven and then stitched together by a separate set of threads called binder threads, or by a few threads of each set being woven into the other cloth. This makes a two-ply cloth, and in the case of belting and other cloths for use in manufacturing purposes as many as ten plies or ten separate cloths are woven one above another and stitched together. It is in this way the so-called "bullet-proof" cloth was made. The outside cloth or ply may be of fine material for appearance and the inside may be of a cheaper material for economy, or stronger material to give strength.

A pile fabric is one in which a portion of the yarn is caused to stand erect above the face of the goods. It is woven either single or double. In the double cloth—plush or velvet—two webs of the ground fabric are woven one above the other and a certain distance apart, and the pile warp is passed between the two, being held in each cloth, and later cut, forming two pieces of cloth with pile on the face only. Two shuttles are generally used, and both are thrown on each pick through the two separate sheds, one above the other. The cutting is done by a knife which passes back and forth between the two cloths while they are separated and drawn forward by two take-up rolls. In weaving the single-pile cloth the pile warp is raised above the rest of the warp on each pile pick, a wire is passed through the shed on this pick, and the pile warp is woven over it, the wire being afterward withdrawn. On the end of the wire is a knife which cuts the top of the loop as the wire is withdrawn, forming cut plush or velvet. If the knife is omitted and the end of the wire is pointed only an uncut plush is produced. By combining the cut and uncut plush and omitting the pile altogether, according to a pattern, very beautiful fabrics are produced all in one color. These are very much used for upholstery, both for furniture and for automobiles.

The greater part of all carpet weaves belong in the pile-fabric class: the Brussels carpet which when cut becomes Wilton; the cheaper tapestry and velvet carpet in which the warp is printed before it is woven; the Axminster in which each single tuft is set independently, and in which there is no expensive pile yarn concealed in the goods; and the elegant and costly chenille carpet in which the filling is composed of a narrow woven fabric having a deep fringe on each edge, which when woven into the carpet with the fringe erect forms the pile. The carpet is woven in any shape to fit any room, even circular, and in any width up to thirty feet. In the oriental rugs each tuft is set in separately and is knotted to the warp so that it cannot be pulled out. These rugs are still made almost entirely by hand, although a few looms have been built for this purpose. The Crompton & Knowles Loom Works has built a loom which ties the Persian knot in a rug 9 ft. wide, tying an entire row of knots across the rug at one time, or about 1200 knots.

In the leno fabrics the warp threads cross each other every time the shed is changed and the filling passes. In this way the threads are better held in place in open weaves such as gauze or marquisette. These fabrics are not very widely used.

This is an outline of the various fabrics which are in demand, and for which looms or weaving machines must be built.

EARLY NINETEENTH CENTURY HAND LOOMS

Before taking up the machines in detail it might be well to follow the art of weaving a little farther. Up to about 100 years ago almost all weaving was done by hand looms. These, however, had become very similar in their construction. All were built practically entirely of wood, and consisted of a heavy wooden frame with the warp beam or roll at the back with a friction let-off to prevent the warp from being drawn off too easily. The harness frames were suspended from overhead, and operated by a foot treadle by the weaver. The lay or batten was swung from overhead and carried the reed, and was drawn forward by hand by the weaver after the filling had been passed in order to beat up this filling. The shuttle was thrown by hand from one side and was caught by the hand of the weaver at the opposite selvage. The take-up roll was at the front of the loom, and was turned by the weaver to wind up the cloth after several picks had been woven. This was a very slow and laborious process, but by care and effort very handsome weaves were produced. There are some hand looms in operation today, largely for pleasure or for educational purposes, and a few commercially. There is a sufficient demand for the hand-made weaves by people who are looking for curious and artistic goods so that these looms may be run at a profit, and very handsome bedspreads, table covers and articles of this sort are produced in as elaborate patterns as can be woven on any power loom. A few improvements were made in the hand loom from time to time. The lay or batten was lengthened, and a shuttle box provided to catch the shuttle instead of the weaver catching it by hand, and a picking motion whereby the shuttle was thrown with a stick, actuated by the weaver, was substituted for the throwing of the shuttle by hand. Where a number of colors or shuttles were to be used, several shuttle boxes were arranged so that the weaver could move them by hand into the proper place and throw the shuttle with the picker stick instead of having the shuttles loose and operating them by hand. Almost all the weaving was done in the homes of the weavers. A few crude power looms were built, but they were not largely used. There seemed to be labor troubles even in those days and the weavers would not go into factories, and even destroyed them. Preparatory machinery was very crude, which delayed the production of power looms.

FUNCTIONS OF CERTAIN MACHINE DEVICES

All looms are composed of a number of separate motions, each motion complete in itself, and carried on one frame, and operating at the proper time. All of these are varied greatly according to the character of goods to be woven, the variations being principally as to the weight and strength and the general principles remaining very largely the same. The motions ordinarily used are as follows:

The let-off is a mechanism which carries the beam or spool holding the warp which has been carefully wound upon it in a parallel manner. This let-off allows the warp to be drawn off only as required. Usually a friction drum and band of leather, rope or chain is used to regulate the speed with which the warp is released, but for weaving accurate goods a worm and worm wheel are employed, regulated by the tension upon the warp, thus maintaining the tension somewhat more uniform.

For beating up the cloth or forcing the consecutive picks or rows of filling into place there is the lay which carries the reed. This is usually swung from below near the floor, and is moved forward and back by a crank and connectors. The lay carries on each end the boxes for the shuttles, one on each end when only one kind of filling is to be used; when more than one kind of filling is desired as many as six boxes on each end may be provided. With six boxes on each end usually six kinds of filling are used, although it is possible to use as many as eleven. The use of more than six causes great complication in the pattern for moving the shuttle box.

The shedding motion is used for opening the warp to allow the passage of the shuttle. This motion presents the greatest variety according to the cloth to be woven. Up to five harnesses and where the weave is balanced so that there is always one harness or more moving up and one or more coming down at the same time, a surface cam under the loom and a lever is used to draw the harness down while the corresponding ones are raised by straps and rolls overhead. For more than five, but not more than eight, harnesses a path cam at the end of the loom is usually employed, connections being made to the top of the harness from the top of the cam lever to raise it, and from the bottom of the harness to the lower end of the cam lever to lower it. For each change of pattern in this mechanism an entirely new set of cams is required, and it is necessary to change the cams and possibly the gearing operating them whenever the pattern is changed. When more than eight harnesses are used, and when frequent changes in patterns are to be made, some form of a head motion with a changeable chain or pattern surface which can be readily changed is desirable. The pattern surface is usually composed of a chain or a series of bars linked together, and of such form that the heights of any part of the links or bars can be varied, the height of the link or a portion of the bar indicating the action of the harness. In the so-called Knowles head the chain is composed of a series of round bars, every bar carrying a roll or a riser or ferrule for each harness. The action of the large roll or riser is to raise a vibrating gear into mesh with a toothed cylinder, which revolves the gear one-half turn, and through a series of connectors and levers raises the harness into its upper position. A sinker or a tube causes the gear to mesh with another toothed cylinder, revolving in the reverse direction, and lowers the harness. In a dobby, wooden bars fastened together by links form the chain. The levers which raise the harness are moved by hooks, which are normally hooked on to a reciprocating bar, raising the harness each pick. The pegs in the wooden bars lift the hooks from the bars and cause the harness to remain down or in the lower plane, the pegs being inserted in the wooden bars so as to form a pattern. These heads are made up to a capacity of thirty harnesses and are capable of weaving a pattern of any length up to many hundreds of picks.

The picking motion throws the shuttle across the loom through the shed to lay in place the lines of filling. It is nearly always composed of a quick-acting cam attached to a stick by levers and a connector, the upper end of the stick being behind the shuttle so as to throw the latter across the loom.

The take-up is the mechanism which draws the cloth forward as it is woven and winds it onto a roll at the front of the loom, the roll being given a slow revolving motion by ratchet and pawl or a worm and wormwheel connected to the roll by a train of gearing.

Looms when belt driven are always operated by means of a pulley which can be quickly connected. Formerly a tight and loose pulley was used, but more recently the usual construction is a pulley with a side-friction clutch which will release very quickly, although for the heavier types of looms an internal-expansion clutch is considerably used. The pulley is mounted either on the crank shaft or one parallel to it, and attached to it by gears, or the pulley shaft may be attached to the crankshaft by means of bevel gears and run at right angles to it, according to which ever method is best adapted to the shafting of the mill. At the present time looms are very largely driven by individual motors, in which case it makes no difference at which angle the pulley shaft is placed.

Box-Motion Mechanism

The box motion, so-called, is another important motion. It is the mechanism which determines which shuttle shall be thrown across the goods in a loom where several shuttles are in use. The boxes are moved up and down at each end of the lay, and the one from which the shuttle is to be thrown is positioned level with the shed on each pick. Also the box to receive the shuttle is placed in a similar position at the opposite end of the loom. In looms where only two or three boxes are used and where the number of changes are small, perhaps only three or four and then a repeat, this is accomplished by a simple cam and lever. The color or the box pattern is apt to be very long, longer even than the pattern for the weaving, and for more than a few changes a mechanism with a changeable pattern chain or surface is used. This is quite often very similar to the Knowles head-shedding motion, lifting the boxes in place of the harness, and oftentimes it is composed of a gear with a sliding tooth or a sliding intermittent gear which is moved into mesh by the use of the pattern chain, and turns the gear one-half a revolution, raising or lowering the boxes. For two boxes only one gear or one set of gears in Knowles head is required. For four boxes two sets of this mechanism are required, and they are attached to the boxes by compound levers so that four positions can be obtained, and for six boxes three sets of compound levers are used.

The color patterns are apt to be very long, particularly in the case of towels, blankets, scarfs, etc. Usually each color is used for a number of picks, and the various groups of colors usually can be made multiples of each other. This fact is taken advantage of to reduce the amount of pattern chain required. The mechanism which accomplishes this is called the multiplier. If for instance the common divisor of all the groups of colors is ten picks, a small chain of ten bars is added to the loom, and each revolution of this small chain changes the main chain one link, thus dividing the amount of pattern chain required by ten. Where the pattern runs as far as the middle of the piece of goods and then reverses, as is quite customary in towels and goods of that character, this fact is taken advantage of by reversing the chain for one-half the pattern, thus cutting in half the amount of chain required.

Automatic Stopping Devices

When power looms came into use it became necessary to apply various devices for safety and for stopping the loom in order to prevent damage to the cloth or to the machine in case of a failure to operate correctly. A filling stop motion, so-called, is applied to stop the loom in case of a breakage of the filling or weft in order to prevent a defect in the goods. A warp stop motion is applied which answers the same purpose in the case of breakage in the warp.

A protection is added to the loom which stops it instantly in case the shuttle should fail to pass entirely through the shed. If it remained in the shed and was beaten up against the cloth by means of the lay it would cause serious breakage in the warp, and very likely break the shuttle or some other part of the loom.

In the ordinary looms the weaver is required to remain close enough to the machine so that she will notice when the filling in the shuttle becomes exhausted, and replenish it before it becomes entirely used up, and she is obliged to put each bobbin in the shuttle by hand. This limits to some extent the number of looms which one weaver can operate, and to overcome this and make for greater efficiency the automatic or magazine loom has been developed. This is made suitable for two, four, or six colors, and by means of a so-called filling detector it notes the approaching exhaustion of the filling before it is entirely gone, and replaces the empty filling bobbin or carrier in the shuttle without stopping the loom, selecting the proper color for each shuttle. This enables one weaver to operate as many as sixteen looms, the number depending upon the character of the warp and filling. These looms are of course equipped with warp and filling stop motions, and are so nearly automatic that in many mills where the power is kept in operation during the noon hour the weavers fill the magazines and leave the looms running when they go to dinner, and find many of them in operation when

they return. Some of them will be stopped due to fault in the warp or filling, but without damage to the fabric, and it is only necessary for the weaver to piece up the warp and filling and start them going again.

In heavier and slower-running types of looms another device is frequently used for automatically supplying the loom with filling. This is known as a shuttle changer. In this device the entire shuttle is removed from the loom when the filling is practically exhausted, and a new shuttle with full filling is substituted. This takes place as in the magazine loom while the loom is in operation, and without interrupting its motions in any way. This type of mechanism is of particular advantage when applied to looms in which the filling is customarily wound on a butt instead of on a bobbin.

The Jacquard

Another very interesting and clever device for use with these looms is the jacquard, which was invented by a Frenchman of this same name in about 1800. When complicated patterns or patterns of great length are to be woven there is no combination which can be made so that the warps can be grouped and handled by heddle frames. Each single warp thread must at times be individually raised and lowered, and to accomplish this each thread is passed through a "maileye" in a heddle. At the lower end is a weight or "lingo" to draw it down. The upper end is passed through a board above the warp in which holes are drilled for each cord to hold it in place. Where the pattern repeats itself across the goods the similar cords from each pattern are brought together into one neck cord, and these cords pass to the jacquard machine above the loom. Here the cords are attached to the lower ends of upright wires in the upper end of which a hook is formed. These hooks are arranged in rows, and in front of each row is a knife or "griffe" which is constantly moving up and down in the proper time. Normally the hook is free from the griffe. Near the top of the hooked wire is a projection on a horizontal wire bearing against the upright wire in such a manner that if the horizontal wire is moved lengthwise it will place the hook in engagement with the griffe. There is one horizontal wire for each hook. They are arranged in horizontal and vertical rows. At the outer end of these horizontal wires is a rectangular cylinder mounted so that it can be revolved, and moved to and from the wires. This cylinder carries on it a series of cards, and presents one card to the wires each pick. The card is pressed against the ends of the wires, and unless there is a hole in the card the wire is moved lengthwise, causing the upright to engage the griffe, which moving up raises the cord and its corresponding warp thread. Holes are punched in the cards so that only the wires which are selected will move lengthwise, and the holes are punched in such an arrangement that they will weave the desired pattern. This machine is a development of a so-called old draw loom in which the cords were bunched together and pulled by the hand of

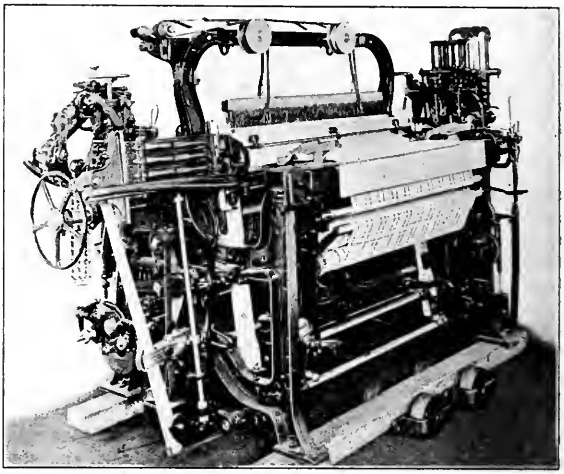

Fig. 3 Automatic Gingham Loom

a draw boy who attended to this part of the process while the weaver attended to the remainder.

Different Types of Looms

To weave all the various fabrics which were first mentioned a great number of different types of looms are of course required.

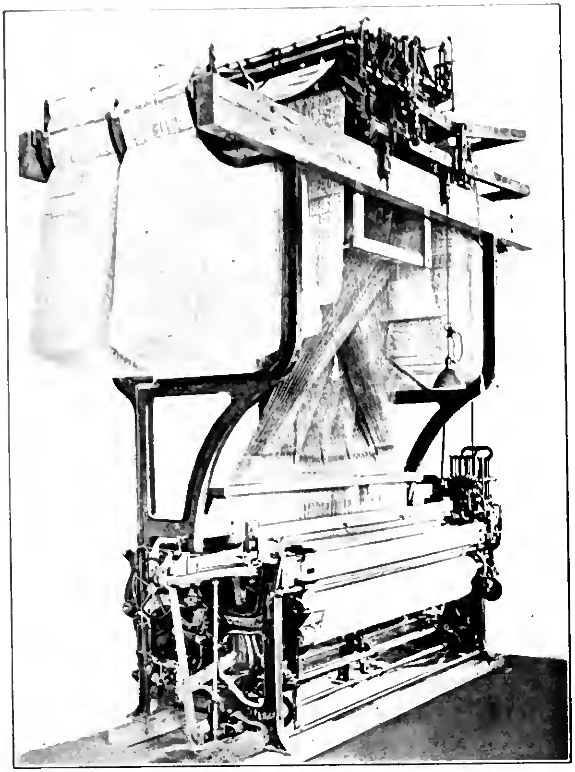

Fig. 6 Automatic Table-Damask Loom

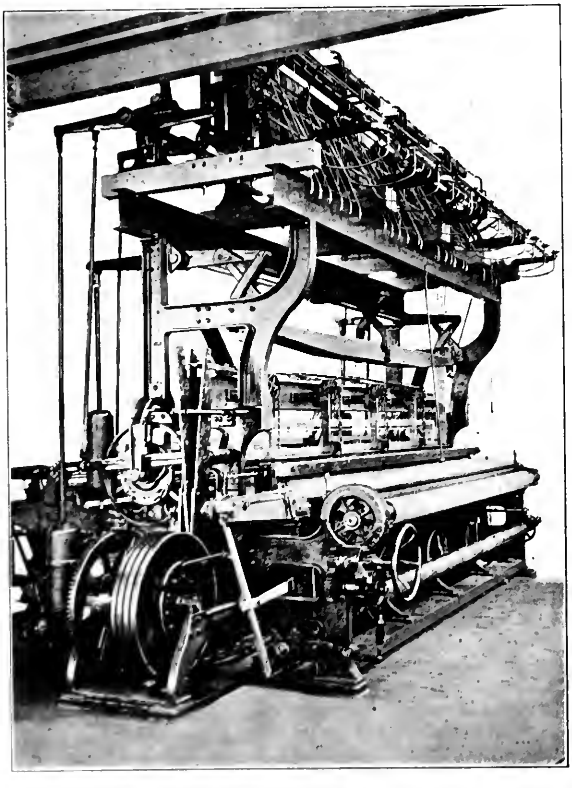

Fig. 9 Stationary Wire Wilton Loom

The simplest are naturally those for the plain weave. The shedding motion for this class is the face cam under the loom, pulling one harness down, and straps and rolls raising the opposite ones. The principal variation in these looms is in the weight and strength. They run all the way from the light cotton loom weaving print cloth or muslin 27 in. wide up to those which are suitable for ducks and tire fabrics (Fig. 1), and finally to those machines for the heaviest or 12 0 duck up to 240 in. or 20 ft. in width. This is probably about as heavy fabric as is woven. The loom (Fig. 2) for this purpose weighs about thirty tons. This fabric is used for receiving wet-pulp and paper-making machines.

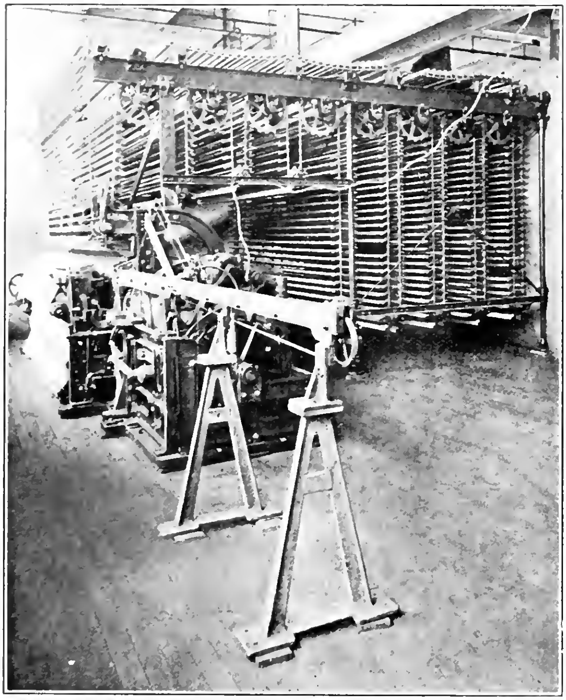

Fig. 10 Smith Axminster Carpet Loom

The gingham loom (Fig. 3) is very similar in construction to this. It is equipped to handle two, four, or six colors, and is therefore equipped with a box motion. The pattern for the weaving is only two, three, four or five harness, and so the simple cam shedding motion is employed. The color pattern, usually being checks, etc., is of great length, requiring a very long pattern chain, and therefore the loom is equipped with a multiplier.

Looms for weaving silk (Fig. 4) are of great variety, plain looms where the cloth has only one kind of filling, and two shuttles for weaving crepe, requiring two kinds of filling up to four and six colors for the fancy silk. They are almost always built for many harnesses, usually twenty or more, not only so that the fancy patterns can be woven, but also so that in weaving plain goods the warp ends can be divided into more groups and placed on more harnesses on account of their fineness and the great number.

For weaving the ordinary fabric of clothing for men's and women's wear there are the heavy-worsted looms, intermediate and dress-goods looms. These are all very similar except in weight and strength. The first loom is suitable for heavy cloth such as overcoating and men's wear in general.

The intermediate-worsted loom (Fig. 5) is similar in almost all respects except being of lighter weight for the lighter weights of men's wear, etc., and the Gem loom or dress-goods loom is still lighter, but in general is similar to the other looms, and is intended mostly for material for women's wear. These looms nearly always have the full fancy Knowles head so that almost any pattern can be woven. They carry four shuttle boxes on each side of the loom so that it is possible to use a maximum of seven shuttles although more than four shuttles adds greatly to the complication of the pattern chain for the boxes, and are not generally used.

Looms for table damask (Fig. 6) are usually plain looms, but having very large jacquards on account of the large and complicated patterns which are woven, there being seldom any repeat in the pattern in the entire table cloth.

Looms for weaving blankets are usually built with the cams at the ends of the loom, as many as eight harnesses being used for weaving double blankets. They provide for a great length of pattern for the colors or boxes as blankets usually have a border on each end. For fancy blankets a jacquard is almost always used.

Felt looms (Fig. 7) are very similar to the ordinary looms for weaving worsteds, and are notable only for their great length; the longest loom being 480 in. in length or 40 ft., and weaving a cloth in the form of a tube, which when cut would be equivalent to an endless belt about 76 ft. long. These cloths are used to form a paper-conveyor belt in paper-making machinery.

There is an endless number of looms for more or less special purposes: the cane loom for weaving rattan seats for trolley cars and similar material in which the filling is drawn across the loom by means of a nipper carried on the end of a needle; looms for weaving various kinds of grass and straw matting, which are comparatively simple and have special requirements for the kind of matting which they are intended to weave, those for weaving grass rugs having a very large shuttle; looms for weaving hammocks, and looms for weaving mosquito netting, which products are of the leno type.

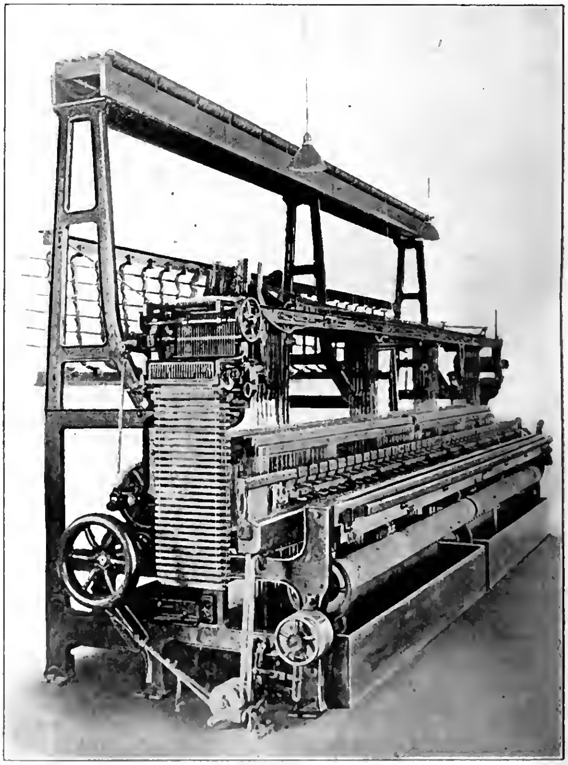

Fig. 11 Ribbon Loom

There are also the looms for weaving terry or Turkish toweling. In these looms the reed or the lay is held back from making its full travel forward for two or three picks according to the character of the goods. These two or three picks bind a portion of the warp to the filling and on the third or fourth pick when the lay is allowed to complete its travel a portion of the warp is carried forward and formed into a loop; The portion of the warp which makes the loop being released from any tension in the let-off at the proper time.

The looms for weaving velvet and plush are similar in construction except, for the double plush or double velvet, the lay carries two shuttles one above the other and these shuttles are thrown through two separate sheds, one from above the other. The pile is controlled by a separate let-off which releases a certain specified amount of pile at each pick and holds the two pieces of goods a certain distance apart. They also have in addition the cutter motion which passes a knife forward and back between the two pieces of cloth each time, the cloth being stretched tightly and held apart by the take-up rolls. Single plush is woven on a loom very similar to those used in weaving carpet, a wire being passed through on each pile pick. They are similar in other respects except that they have the wire motion which passes the wire through the shed.

The constant demand for new fabrics and for very special materials make the combinations and varieties of looms which are demanded almost endless.

There are also looms for weaving the various kinds of carpets (Fig. 8). The Brussels loom, with a knife placed on the end of the wire, makes a Wilton carpet (Fig. 9). In this loom there is a jacquard and a wire motion. The wire motion passes the wire through the shed on each pile pick, and the looms are built to weave carpet up to 12 feet in width or 16/4. In this carpet there is a set of worsted warp threads for each color which appears in the pattern, four, five or six sets of worsted yarn or frames, as they are called. There are seldom more than six frames or more than six colors used. The pattern is formed by raising the color required over the pile wires so that it will appear on the face—the balance of the worsted yarn being buried in the back of the carpet, the different threads being raised so as to form the pattern in color. Thus the greater part of the expensive yarn is buried in the back of the carpet and cannot be seen, and while it makes a very soft and beautiful carpet it is also very costly.

The tapestry loom for weaving tapestry carpet, which when cut forms the Wilton, gives a similar effect in a much cheaper way. This loom is very much the same as the Wilton loom except that no jacquard is employed, and there is but one set of worsted-yarn threads, and on these the pattern is printed on the warp before it is woven; each thread being of different colors throughout its length, and each thread is always on the face of the goods, but put together in such a manner as to form the pattern, the thickness and body of the carpet being provided by a stuffer. The warp is printed on a printing drum, each single thread being wound on a drum of such circumference that one turn carries sufficient yarn to make one repeat of the pattern. A printing wheel carrying the color is then drawn across the face of the drum, coloring just sufficient length of thread to form one tuft or loop. The proper number of threads to form the entire warp are printed on different drums and they are then matched together so as to form the pattern, wound on a beam and made ready for weaving.

In weaving the Axminster carpet (Fig. 10) each tuft is set into the carpet separately, and there is no worsted thread running lengthwise of the carpet or concealed in the body. The pile or tuft yarn is wound on small spools of sufficient length to make the entire width of the carpet. There is one spool for each row of tufts and there are as many threads on the spools as there are to be tufts in a row. These threads are of various colors so arranged on the spools that they will form the pattern. They are carried in a chain and one spool is presented to the loom each pile pick. The loom lifts the spool from the chain, lays the yarn in the carpet, the warp binds it in place, and the loom cuts it off from the spool and returns the spool to the chain. The chain moves forward one station and presents the next spool to the loom, the process as noted above being repeated. For a rug 9 ft. by 7 ft. there would be from 500 to 700 spools in accordance with the fineness of the carpet, and there would be from 400 to 600 threads on each set of spools.

In the chenille carpet two looms are required to produce the carpet, one to weave the weft for the main loom. The weft looms are small machines of plain construction and they weave a number of lines of fringe or chenille, which when spread lengthways makes a narrow fabric only a few threads wide with a wide fringe on each side. This in turn is used in the main loom as filling. The loom weaving the carpet runs for three picks and then lays a row of the chenille in the loom and stops, and the weavers comb the fringe or pile into a vertical position by hand, when the loom is started again. In much of the chenille where the pattern is at all complicated the chenille is put into the loom by hand, the chenille being wound on a stick and passed from one weaver to the other lengthwise of the loom.

For weaving ribbon (Fig. 11), tape and all narrow fabrics many pieces are woven at one time in one loom. There is a shuttle and a weaving space for each piece of goods, but the shuttles instead of being thrown across the loom by a picker stick as they are in what is known as a fly-shuttle loom, are moved positively from side to side. There is a block about the length of the shuttle on each side of the weaving space, and on the bottom of the shuttle is a rack. In this rack is meshed a pinion turning on a pivot in the block. Below the cloth and meshing with the lower side of the pinion is another rack passing the whole length of the loom and meshing with the pinions which drive each shuttle the whole length of the loom. As the rack is moved lengthwise it turns the pinion and forces the shuttle from the block across the weaving space. On the other side of the weaving space is another shuttle turned by the same rack which picks up the shuttle before it leaves the first mentioned pinion and carries it into the block. The motion of the rack is a reciprocating one and when it is moved in the reversed direction it carries the pinion back across the weaving space and into the first-mentioned block. The other motions of looms of this type are practically the same in construction as those for weaving broad fabrics, and are varied to suit conditions.

BURNING BITUMINOUS COAL ON TYPE E STOKERS

(Continued from page 374)

Care is taken to have the fire from 10 in. to 12 in. thick, keeping the draft over the fire as indicated by the draft gage at about 0.5 in. Under these conditions the draft under the fire will average from 3 in. to 5 in. and the draft in the last pass about 0.4 in. to 0.6 in. These figures are for our usual running conditions at 100 per cent rating.

The variations will depend on whether the coal is largely dust or in small lumps and whether it cokes to form a crust which prevents air supply. The greater the tendency to coke, the greater the air pressure required.

The firemen are instructed to keep the fire level and to use the fire tools as little as possible and to keep the draft above the fire uniform. The fires are dumped every $2^{1}/_{2}$ hours and very little trouble from clinker in the ash dump is experienced.

Approximate analysis of coal fired in two boilers which, operated at from 125 to 150 per cent rated capacity, are sufficient to carry our load at all times, is as follows: carbon, 71.17, volatile, 20.04, ash 7.70, sulphur 1.09, moisture 1.20, B.t.u. 14,643.

About 1500 lb. of coal is burned per hour during the day in each furnace, which has a projected area of 71 sq. ft., and about 1050 lb. per hour during the night. The stoker speed is hand-controlled. Two of the boilers are equipped with the Bernitz furnace walls for admitting air above the fire all around the furnace, the other two admit air through openings in the rear wall only. We have had very little trouble with clinker on the walls of any of these boilers. Ash is wet down in the ashpit immediately after dumping and is removed from the ash hoppers in basement by cars of about 1000 lb. capacity. No scales are provided to weigh the ash regularly, but occasional weighing indicates about 12 per cent ash by weight of coal burned. This includes water in ash.

Operation is practically smokeless. There is no dense black smoke at any time, and light smoke during short periods only. Air is admitted over furnace to secure good combustion between fuel bed and tubes. The lower side of the front header is 10 ft. from the floor line and combustion is complete before the hot gases reach the lower tubes.

During the fifteen months the stokers have been in operation, no trouble due to manufacture or design has been observed. When first put into service, however, several grate bars were burned out, due to the failure of the firemen to remove the siftings from the central air box promptly.

Management Applied to Textile Plants

The Organization of a Cotton Plant and Its Management—Comparison of Cotton-Manufacturing Development in the North and South

By GEORGE S. HARRIS,[1] ATLANTA, GA.

A COTTON mill is a highly organized plant consisting of four or more distinct departments, all quite different, and to master the details of any one requires long study. The departments in order are, mechanical, carding, spinning, weaving, and cloth. The last named includes the classification, branding and packing.

The stock in process, cotton, consists of fibers very sensitive to atmospheric conditions and easily damaged in working. This fiber under a microscope appears like a minute glass tube slightly flattened and slightly twisted. It is covered with a very thin coating of wax, normally has a moisture content of about 8 per cent and beyond the carding process works better when the moisture content is held at or about normal. The effect of picking and carding is to dry out the moisture and as it is in these processes we attempt to separate the good fiber from the dirt, leaf, and short and immature fiber, we need to have the stock dry to properly effect this separation. Beyond the carding we begin the parallelization of the fibers and evenly drawing down the stock through different processes until the required yarn sizes are ultimately reached.

During these processes the atmospheric conditions must be controlled, as it is quite apparent that unless the correct percentage of moisture is maintained in the air surrounding the fibers at the prevailing temperature, the air is going to extract from or deposit on the fiber the shortage or surplus of moisture as the case may be. It has been determined by engineers experimentally just the percentage of moisture necessary to be maintained in the mill atmosphere throughout the range of temperatures to effect the necessary regain in moisture content of the cotton fiber. It naturally follows that a certain moisture content in air at one temperature would not be correct at another.

In addition to the departments referred to we very often find a finishing department, including bleaching oi dyeing or both. In fact, with some few exceptions, all cotton goods are given some kind of finish after leaving the loom before they are ready for consumption.

Department Personnel

To properly man such an institution as this we must have at our command men of various qualities and training—the master mechanic, the carder, the spinner, the weaver, and finally the finisher. In the older countries where competition is keener and men progress only by specialization, we seldom find a manufacturer attempting the whole works as we do here, especially in the South. There, one mill produces yarn only and attempts only carding and spinning. Another mill attempts weaving only, buying its yarns from a man devoting his whole time and attention to carding and spinning. Likewise the cloth is sold as it comes from the looms to a converter who has it finished by a man who possibly doesn't know a loom from a card but has spent his years training in the arts of chemistry, of dyeing and allied subjects. Whether the one system is better than the other is a question for debate, but as the industry is successful under both systems, probably local conditions in either case had their influences in its development.

The mechanical department consists principally of power plant and shops, but in reality extends over the entire plant to reach all power-transmission equipment, fire protection, service lines, steam and water, sanitary system, machine repairs, building repairs, etc. All of this very naturally requires for its directing head a man trained in the many branches of engineering, mechanical, electrical, and otherwise. In the South the plants are often isolated and the mechanical department sometimes finds itself in deep trouble and thrown absolutely on its own resources. The head of the department must be competent to demand and hold the respect of the heads of other departments who are not mechanics, and to stand firmly in the organization as his title implies—master mechanic. No position in a textile plant is of more importance.

The general appearance, or we might call it the tone, of a textile plant depends on the character of the master mechanic, and frankly only a small percentage of the men who have come under my observation fully meet the requirements.

Continuing our trip through the plant, we find the carder. He has his picking, carding, drawing, slubbing, and roving—all different processes—with every pound of the stock passing through each process in the order named and in constant danger of being damaged. The carder, as do all department heads, has his department divided into sections, with each section under the care of a "section man."

In the next department we find the spinner, who receives the stock from the carding department in the form of roving wound on wooden bobbins. This roving is specified as a certain "hank" roving. By this is meant that a certain number of hanks will weigh a pound. For instance, a four-hank roving means that the stock has been drawn down to such a size that four times 840 yards (one hank) will weigh a pound. The roving must be evenly drawn. That is, it must be reasonably free from thick and thin places, it must be properly carded free from specks of leaf and have the greater portion of the short fibers removed, and it must have only sufficient twist to make it hold intact while being wound on the bobbin and off again. The head of this spinning department must see that this roving (his raw stock, so to speak) is up to specifications. He has in this department spinning, spooling and warping and delivers to the weaving department warp yarn wound on large spools, or beams, as they are called, and filling yarn wound on wooden bobbins or cops, in condition to go directly to the loom shuttle.

Next as we follow the stock through, we find the weaver, who usually has in his division of the plant slashing or dressing, warp preparation, and finally weaving. To fully meet requirements he must know cloth analysis to be able to positively determine yarns, harness, reeds, and loom "set-up" necessary to produce a cloth without unnecessary cutting and fitting, which unfortunately is common practice with many. In the slashing of warps, to produce not only the correct finish on the cloth but a good running loom, requires a knowledge of starches, fats and various chemicals brought together in making up the finished size which is pressed into the yarns and dried over large copper drums.

The finishing department, whether it be bleaching, dyeing, or both, finally finishing the cloth into one or more of the thousands of finishes given to cotton piece goods, is a department very different from any we have yet seen. In this department you will probably find a chemist with his laboratory prepared for testing the great number of dyestuffs and chemicals required to produce the different finishes. You will find the dyer, trained by experience and experience only, to produce the great number of shades required, and then the finisher, who takes the dyed or bleached cloth and gives it the feel, sheen, etc., required.

A department head lacking in the mental capacity, training and industry necessary to hold up his end will surely drag down all other department heads to his level—and this can often be accomplished in a remarkably short time. This is due to the fact that cloth manufacturing consists of a long series of processes through which this very sensitive cotton fiber must pass on its way from the bale to the case of finished goods, and to the fact that at any point serious damage can occur which is very difficult to detect at once but which readily shows itself in the cloth-testing laboratory. Many a mill manager has been worried for months with the knowledge that certain of his fabrics are not up to standard quality and yet has been unable to locate just the process that is causing the damage.

[1] President, Exposition Cotton Mills.

Presentation at the Spring Meeting, Atlanta, Ga., May 8 to 11, 1922, of The American Society of Mechanical Engineers. All papers are subject to revision.

Management and the Manager

The general subject of management has always been an interesting one to my mind, and I believe that during the next few years managers as a class all over the globe are to meet trials never before encountered. We are all familiar with the three-legged table supporting industry—the labor leg, the capital leg and the management leg. It is generally conceded that no three-legged table can stand on only two of its legs, but occasionally we hear of a labor leg somewhere deciding that his particular table is fully able to stand without the management leg, or in some cases the labor leg feels that the table might be more substantial if we take some of the stock out of the management leg and put it into the labor leg. Naturally the table is weakened directly in proportion to the amount of stock removed from any one of the legs.

Management, to my idea, is more or less a matter of compromise and it is just as erroneous to uncompromisingly dictate to men without feeling their sensitiveness, as it is to attempt to twist a cotton fiber in a way it will not twist without damage.

Men—and of course I mean men who have not been advanced beyond their capacity—should feel their responsibility and should be allowed to work out their problems in their own way. A manager to stand firmly as such must have had the necessary experience in all the various departments, and he finds it difficult at times to see an assistant apparently wasting time by taking a circuitous route to an object, but the man should be allowed all possible leeway and be checked only when he is about to do some real damage. It is to my mind poor management to feel that every man must be made to do my way. Unless a man is given an opportunity to try out his ideas without fear of being discharged for mistakes, he stops thinking and becomes a machine.

Men should be taught to feel that it is their duty to train other men. They should be taught by the management that their advancement depends always upon their having ready an understudy. I recall reference in a paper once to the "three-point system of promotion" and have always remembered my impression. Picture an organization from manager down where each man in line is trying to promote himself by making the man ahead so good that he must outgrow his shoes and at the same time training an understudy for his own work. You have then an ideal organization.

When a vacancy occurs a good man will comb thoroughly his own organization before going outside, but I don't think a manager should ever promote a man unless that man can show that one or more of his assistants is ready for his work. When a man is fully filling his part in an organization he is continually pushing forward the man just ahead and pulling the man just below. No man, regardless of his competency, should ever receive promotion who has ever attempted to drag down another in his organization or in any manner attempted to interfere with his progress.

Plant managers require the full loyalty and attention of every man on the staff, and a manager who does not possess that personality so necessary to develop loyalty and interest in his assistants, is surely unfortunate and so are his stockholders.

There is hanging on the walls of my office a card bearing this inscription by Elbert Hubbard: "Men are valuable just in proportion as they are able and willing to work in harmony with other men." Please get this firmly in mind. Several years ago I had copies made and posted them throughout our plants and have been interested in seeing its effect on the men. I commend this to employee and employer alike as carrying a lesson well worth any man's careful consideration.

In industrial management today we have two extremes. On the one hand an uncompromising autocrat who sits at the head of an organization dictating without regard to the thought or feeling of the men in charge of departments, and on the other hand the recently developed industrial democracy with the governmental bodies of men from the works either appointed by the head of the establishment or elected by the workers en masse, or both.

I feel that either one of these extremes is just as bad as the other and both with few exceptions will eventually go on the rocks. I have more tolerance for the industrial democracy plan of management than the autocratic management, but neither is good nor necessary. Somewhere between the two ideal management is found.

Here you find a man firmly in his position by reason of his personality, capacity and training. He knows his work and can intelligently direct with an understanding of the difficulties ahead of the men when they attempt to carry out his instructions. He is naturally careful and thinks out his plans after discussing details with the men who are ultimately to do the work. This is not possible for any man to do before he has mastered details in the plant. An industrial plant is not a military establishment and cannot be successfully handled as such. The main object in any army, it seems to me, is to "pass the buck," while in industry every man in authority should be prompt to stand firmly on his responsibility and never attempt to shift his burdens to others.

The industrial democracy idea is pleasant to think about as it carries beautiful ideas of the brotherhood of man, etc., but human nature is the same the world over and in my opinion this plan generally will not succeed. There will be found an occasional exception where local conditions or some man or men in the organization are gifted with certain qualifications that make it all a success. But these exceptions are and will be rare. Men of today have developed through a long process of the "survival of the fittest" and the result has been a certain amount of selfishness in all men. Those who had no selfishness in their make-up and insisted upon giving away to others everything they gained, were stamped out before our day and left no posterity.

Southern Cotton-Manufacturing Development

It has been suggested that you might be interested in a few ideas on the development of cotton manufacturing in the South as compared to that in other sections. As you know, for a term of years our development was phenomenal, until today the cotton-growing states are making into yarn or cloth considerably more than half the cotton manufactured in this country. Of the 37,000,000 spindles in the United States, the cotton-growing states have 16,000,000, or more than 43 per cent. The mills of the cotton states are now consuming 55 per cent of the cotton consumed in the country, with a steady increase. This has been accomplished in comparatively a very short time and it might be interesting to see how it was brought about.

Before the successful development of the humidifying apparatus, cotton mills were confined to certain localities in which could be found natural atmospheric conditions permitting weaving and spinning. This very largely accounts for the mills of England and later those in our New England States. In the Southern States the hot, dry summer so necessary to the growth of cotton did not encourage the spinner and the few mills we had in the old days were located on the banks of rivers for the dual purpose of supplying power and natural humidity. Some mills were scattered over the South, but the real growth was in New England.

In 1881 a few leading citizens of Atlanta conceived the idea of creating something that might stimulate cotton manufacturing, and the result was the Industrial Cotton Exposition. This was held in Atlanta and exhibited everything from the cotton growing in the field to the finished cloth, with the actual manufacturing being demonstrated. As a finishing feature a real wedding ceremony was performed in the building with both the bride and the groom wearing clothes made of cloth produced with the machinery on exhibition from cotton grown in the surrounding fields. Immediately following the close of the exposition a new company, the Exposition Cotton Mills, was organized and began the manufacture of cotton goods on a commercial scale in these same buildings, and from this nucleus the present Exposition Mills have grown.

As the real growth of mills in the South dates from a time soon after this exposition, it seems fair to assume that it was quite largely responsible for this growth and those of us who have the honor today of occupying official positions in the Exposition Cotton Mills feel proud of the part our mills played in the development of our industry. We have today, framed in our office, one of the original certificates of the capital stock of the International Cotton Exposition. More than this, a part of our present equipment is now running in the original wooden buildings that housed the exposition.

The development of southern cotton mills was assisted greatly in later years by the perfection of humidifiers which made it possible

to build a mill anywhere and operate it successfully through the summer months.

It might well be asked why the southern mills advanced so much more rapidly than those in any other section, and I will attempt to answer, in part at least. We will take for comparison a mill in Georgia and another in Lowell, Mass., without any intention of discrediting what has been achieved by our friends of New England. As a matter of fact, we of the South marvel at their ability to show such financial results under their conditions.

First, in the matter of cotton the Georgia mill has the advantage. When the mill in Lowell requires cotton it first deals with a local broker who will probably place the order with one of the many cotton shippers maintaining a large organization covering more or less the entire cotton belt. These shippers in turn will buy the cotton from smaller shippers operating in one locality who might buy direct from the producer or from a merchant who has taken in cotton on account of supplies furnished during the growing season. The cotton, before it can start on its journey, is concentrated at some point for compression. Here it receives considerable handling and is compressed to a high density. By the time it reaches New England it not only has accumulated a very high freight charge, but the percentage of tare has been increased at the compress.

In contrast to this long process with its three to four necessary profits, the Georgia mill will buy generally from the local shipper and might buy directly from the large responsible producer, with transportation cost usually only a few points. In addition to this the mill in Georgia can handle uncompressed cotton, saving the extra tare and expense incident to compressing, besides the extra mill expense in opening compressed cotton. I have never been in a position to make a dollar-and-cents comparison of this cost of cotton, which would naturally vary with the seasons, but the difference must always be there and in some seasons it must be considerable.

The labor cost has always been in favor of the Georgia mill, due as much as anything else to climatic conditions. The long, hard winters of the North necessarily make the cost of living very materially higher, which must be borne finally by the manufacturer in his payrolls. In the South from the beginning the mills found it necessary to provide homes for the operatives as this proved to be a decided economic advantage, both to the mill as well as to the operative. The village plans today are given the same consideration as the mill plans in the original layout. This has given the operative a far more comfortable home at a much less cost to the mill than if supplied by outsiders who haven't the same interest in the operatives or the mill. Furthermore, this scheme of things has tended to keep the relationship between employer and employee closer. Contrast this with the operative in New England who lives in a house probably one or more miles from his work and which he rents from a landlord who has no interest in him beyond that of keeping his property occupied profitably.

There was a time when this was very largely offset by the higher efficiency of the labor in Massachusetts, but this advantage has now been shifted about. With every year our labor has been growing more and more efficient, while the original labor of Massachusetts has been replaced each year at a steadily increasing percentage with untrained immigrants. I recall my first day in Lowell as a boy where I went to take courses in the Lowell Textile School. Standing near a mill gate at noon and observing the help passing out, I had to listen carefully to hear the English language spoken. Instead what I did hear was, as it seemed to me, every language of the world. I learned afterward that twenty-six different nations were represented in the mills of Lowell at that time, and that was more than twenty years ago. This, together with the advent of labor organizations, has created a condition that tends toward anything but efficiency.

In contrast to this, in a Georgia mill is a class of labor, all American, recruited from the farming class. The manager has grown up with them and knows them in their homes. In many cases the mill, being a comparatively young institution, was built from a small unit by the present owners. The manager, living in close touch with the labor, is in a position to talk freely with them. I know of instances in Georgia, during the recent depression, where values depreciated so fast that it was impossible for a mill to continue operating without tremendous losses, but the employees quickly sensed the entire situation and voluntarily submitted to reductions in their pay in order that the mill might continue to operate. Do you hear of such actions in the union-ridden mills of New England? I have not. The result is that while the Georgia mill is in position to sell its product today in line with the depreciated value of raw products, the New England mill has its manufacturing cost held up fictitiously and is forced to take heavy losses in current values or shut down.

In conclusion, allow me to refer again to the legs supporting industry, with special reference to the management leg and American industry. Do you fully realize your responsibility during the next few years? It is up to the management to attract, hold and keep employed labor and capital. They are both free and when management fails to function they both withdraw and industry becomes stagnant. Our recent road has been a hard one, but now the capital is here, the labor is here, and world competition is also here; and it is going to take brains, and active brains in the heads of management, to direct capital and labor so as to place American industry in the front rank and hold it there.

Bleaching

Bleaching, Being a Résumé of the Important Researches on the Industry Published During the Years 1908–1920, by S. H. Higgins, Head of Research Department, Bleachers Association, Ltd., London, England, is a comprehensive monograph. It is limited to the subject of bleaching and the discussion of factors that may affect it, exclusive of the purely technical processes of bleaching. The following is cited as possibly giving the scope of the treaty. Many questions have been raised as to proper way of handling mercerizing. Must the fiber be kept under a condition of strain during part of the process, and to what extent might the mechanical treatment be replaced by chemical action? And if, as some assert, a long staple cotton is necessary for success, is this success due to a change in the chemical or molecular nature of the cellulose, or to an alteration in its physical characteristics induced by the initial processes to which it has been submitted? Among the multitude of advisers it may not be indiscreet to ask whether we know the cause or causes of the peculiar appearance of the fabric following mercerization. One authority states that the fibres untwist during mercerization, and retwist often in opposite directions, and that the luster produced depends largely on the reflection of light by the swollen and retwisted fibers. From this hypothesis the conclusion is drawn, that the mercerizing agent, which is able to produce the highest degree of swelling, shrinking and untwisting of the fibers, gives the maximum lustre. Another view is that luster is due to the smoothness of the surface of the mercerized fibers as compared with ordinary cotton fibers. Mr. W. C. Balls declares that luster is almost synonymous with twist. If all the hairs in a sample are well and evenly twisted, there will be an infinite number of convex surfaces, each reflecting a spot of light. In quoting these various authorities, the object has been to show that other causes than chemical change may operate in producing the desired effect; but if adherence to purely chemical guides had been strict, the same diversity of opinion would have been apparent.

As regards removal of wax by saponification the chemist and the practical man have long been at issue, the former maintaining that caustic soda is the best saponifying agent, while the latter insists that the lime boil cannot be replaced for certain classes of goods. The author seems to agree with the bleachers in upholding the value of lime boiling, at least in some cases. He points out and, as it would seem rightly, that in the lime boil and "sour," that unsaponifiable portion of the wax and free fatty acids are left on the fiber, and in the lye boiling a soap is readily produced by the alkali and the fatty acid, resulting in the emulsification and elimination of the unsaponifiable portion. The difference of opinion probably arises from the various classes of goods and their variety of composition, to which the method is applied.

The author's work may be particularly valuable in preventing the repetition of many experiments that have been thoroughly tested: in suggesting ones along which progress is likely to reward research; and in delineating the limitations which the practical man may expect to encounter. AIR ENGINEERING

Calculation of Pressure Losses in Conduits Carrying Air, Steam or Water. V. LeBeau. According to the author's statement, the formulas given for pressure losses in fluid conduits are incomplete and lack precision because of their failure to take into consideration to a greater extent than is done the nature of the inner surface of the walls of the conduits; and further, because of lack of sufficient attention to such obstructions, as, for example, pipe joints. Thus, for example, Lorenz' formula in the Huette Engineering Handbook is found to be valid only for the case of compressed air, and then only for conduits from 50 to 350 mm. (1.96 to 13.7 in.) diameter.

The method adopted by the author is based on the use of the Reynolds coefficient, and a general formula for loss of pressure is developed in which certain coefficients are introduced to take care of the variations in the roughness of the conduit walls.

As regards the roughness, the author divides all conduits into four classes, viz., smooth conduits (drawn lead, copper, brass, or other tubing, the surface of which has been worked to a smooth finish); "first-class rough" conduits, which are iron and sheet steel tubes; "second-class rough" conduits, viz., cast-iron and cast-steel pipe, in which the resistance to the flow of fluid is greater than in conduits of the preceding two categories; "third-class rough" conduits, to which class belong wrought-iron, cast-iron and cast-steel pipes bearing incrustations or deposits on the inner surface.

Each of these four categories is discussed in detail and a formula derived for it, in addition to which the author has worked out curves from which pressure losses in a given type and diameter of conduit may be read off at once.

The article is of very considerable interest, but unfortunately cannot be abstracted more completely owing to lack of space.

As an appendix is given a brief discussion of the formula for determining the specific volume of superheated steam. The author rejects the formulas of Linde, Callendar and Tumlirz and expresses a preference for Zeuner's when so corrected as to bring it into conformance with modern views as to the variability of the specific heat of superheated steam with pressure and temperature.

In this way he obtains the following formula:

$$V = v + 100 \times C_{pm} \times \frac{t_1 - t_2}{P}$$

where V = the specific volume of superheated steam; v = specific volume of saturated steam; C_{pm}, the average specific heat of superheated steam; P, absolute pressure in kilograms per square meter; t_1, temperature of superheated steam in degrees centigrade; t_2, temperature of saturated steam in degrees centigrade. (*Revue Universelle des Mines*, Series 6, vol. 12, no. 4, Feb. 15, 1922, pp. 301-327, 8 figs., 2 charts, *tmA*)

AIR MACHINERY

Rotary Compressor with Disk Piston Moving in a Conchoid

Planche Rotary Compressor, Lucien Fournier. Description of a rotary compressor designed by a French engineer, R. Planche, based on a mechanical movement in which the transverse section of the cylindrical body of the pump is a circle enveloping a conchoid of a circle, the properties of which will appear from the following description.

The principle of action is as follows: A and B, Fig. 1, are the points of intersection of a straight line CD with the circumference of a circle about the center O. If, now, we lay off on this straight line on both sides of B two distances of lengths BC and BD equal and constant and greater than the diameter of the circle about O, the loci of the points C and D obtained by turning the straight line around the point A will be a conchoid of a circle, symmetrical with respect to the diameter passing through the point A which is the pole of the conchoid. All the chords of the conchoid passing through its pole are equal. In order that the two extreme points of the straight line CD of constant length should describe a conchoid, it is sufficient to make the point B the middle point of the line to move at a constant angular velocity about the center O in such a manner that it should describe the circumference of a circle, and at the same time the line CD about its middle point B in the same direction but at an angular velocity only half as great.

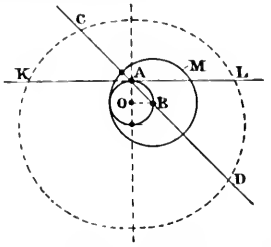

Fig. 1 Diagram Showing the Principle of Generation of a Conchoid

In order to obtain the combination of these two movements all that is necessary to do is to roll along the circle O without any slip, the circle M of double radius, this latter circle moving in one piece with the straight line CD. In this manner, while the straight line passes through a semi-rotational movement, its center B performs a complete rotation, as a result of which the totality of the areas located on both sides of the straight line in the interior of the conchoid is inversed.

If we substitute for the straight line CD a blade moving in the interior of a cylinder having a conchoidal base, we obtain in each period of complete rotation of its center B an intake and an exhaust, notwithstanding the fact that the blade has described only half a rotation in its enclosure. This is the principle on which the Planche rotary compressor is based.

In actual practice, however, in order to make the machining somewhat easier, the conchoid of a circle is replaced by an enveloping circle of a shape fairly close to the theoretical curve. Instead of the blade a disk piston (Fig. 2) is used, which in one view has the shape of a rectangle, and in its longitudinal section appears as a symmetrical spindle, such that its median axis should occupy the position KL in Fig. 1, which corresponds to the dead center. Its outside surface is tangent to the cylinder.

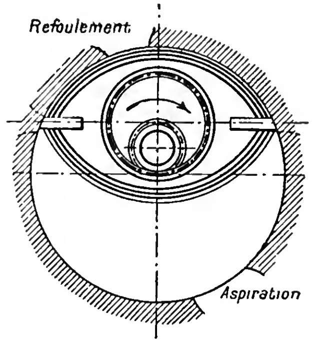

Fig. 2 Diagram Showing the Principle of Design of the Disk Piston, Its Relation to the Dead Center and the Relative Positions of the Intake and Exhaust Ports

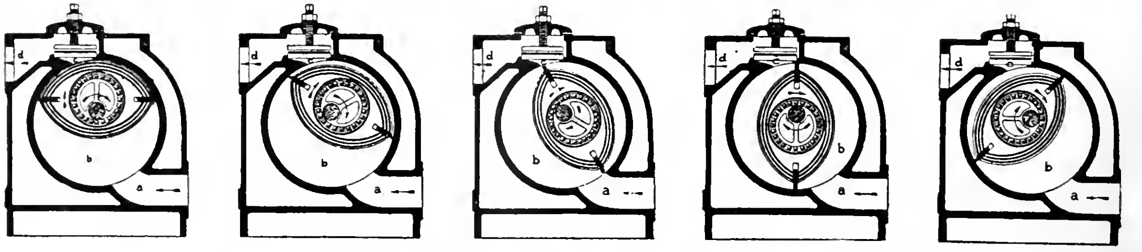
(*Aspiration* = intake; *Refoulement* = exhaust.)

The movement of the piston is obtained by means of an eccentric, the interior of which is constituted by the disk piston itself. The disk piston carries on both sides of its surface two internal gears which during the rotation of the shaft (Figs. 3 to 7) mesh with two rigidly held gears of half the diameter mounted on the engine frame. In this way the center of the disk piston describes a circle of uniform movement, while the disk piston itself turns around its own center in the same direction, but at half the speed.

Since, further, the disk piston is entirely symmetrical with respect to its own middle point, the centrifugal forces and the pressures are uniformly distributed on all sides and their resultant passes through the center of gravity of the disk piston which coin-

cides with the center of the eccentric. Hence, there is no torsion couple which might tend to oppose the motion of the disk piston around its center. The crankshaft and its eccentric alone absorb all the pressure reactions; two flywheels at both ends of the crankshaft are used to insure the balance of the machine. The question of stresses is discussed in greater detail in the original article.



Figs. 3 to 7 Timing Diagrams for the Disk Piston of a Planche Rotary Compressor.

(In Figs. 3, 4 and 5 the air under its own inertia enters through orifice *a* into the space *b* where it is compressed. The gas compressed in the clearance space *c* expands and restores to the piston the power which it has absorbed during previous compression. In Figs. 6 and 7 the air is taken in on one side of the piston and compressed and exhausted on the other side, the exhaust taking place through *d*.)

The cylinder, as shown in Figs. 2 and 3 to 7, has two ports—intake and ignition—lagging with respect to the dead center of the machine and therefore not passing through the points *K* and *L* of Fig. 2. The lagging position of the ports is given in order to secure a better filling of the cylinders due to the fact that time is given to make use of the inertia of the column of gases flowing into and out of the cylinders.

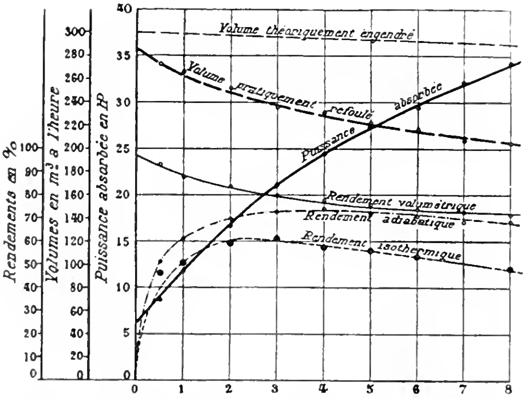


Fig. 8 Curves of Tests on a Planche Rotary Compressor

(*Rendements en %*—Efficiencies in per cent; *volumes en m³ a l'heure*—volumes in cu. m. per hour; *puissance absorbée en HP*—power consumed in hp.; *pression en kgs/cm² (au dessus de la pression atmospheric*—pressure in kg. per sq. cm. gage; *volume théoriquement engendré*—volume theoretically generated; *volume pratiquement refoulé*—volume actually delivered through the exhaust port; *puissance absorbée*—power consumed; *rendement volumetrique*—volumetric efficiency; *rendement adiabatique*—adiabatic efficiency; *rendement isothermique* isothermal efficiency.)

Tests of the device were carried out at the Laboratory of the National Museum of Arts and Manufactures on a unit rated at 300 cu. m. (10,594 cu. ft.) of air per hour, and have given the results shown in Fig. 8.

From this it would appear that the volumetric and isothermal efficiencies of the compressor are very high. At first glance it would appear that because of the high speed of the apparatus the compression should be a little too adiabatic. Actually, however, it is not so, as in these machines the compression and exhaust take place during one complete rotation, and the surfaces which are generated during the rotation are very large as compared with the volume of air which is exhausted, which factor assists good refrigeration.

It is interesting to note that the unit above referred to has also been tested as a vacuum pump and has given a vacuum of the order of 98 per cent. (*Le Génie Civil*, vol. 80, no. 12, Mar. 25, 1922, pp. 275–277, 10 figs., *dA*)

ENGINEERING MATERIALS (See also Railroad Engineering, Machine Parts, Testing and Measurements)

Stainless Nickel Alloy. Description of an alloy recently developed in England. It is known as "newloy" and is composed of 35 per cent nickel, 1 per cent tin, and 64 per cent copper, its peculiar characteristic being the absence of spelter and presence of tin.

It is said that it has already found extensive application for use as tableware. The alloy is very ductile and is made in rods, sheets, stampings and wires. In the latter form it appears that it may be used as a high-resistance wire. (*The Metal Industry* (London), vol. 20, no. 12, Mar. 24, 1922, p. 270, *g*)

INTERNAL-COMBUSTION ENGINEERING (See also Motor-Car Engineering)

Working Fluid of Gas Engines

Some Properties of the Working Fluid of Gas Engines, Prof. W. T. David. The following abstract is given in the words of the author of the article. An attempt is made in the article to clear up certain obscure points in the working of gas engines, and to describe some of the properties of the working fluid which have been ascertained recently from experiments made by the author. Before passing on to a detailed statement it will be convenient to summarize the main conclusions reached.

The article is divided into four sections. In the first section it is shown that incomplete combustion, increasing specific heat and cooling are all important factors in limiting the pressures developed during the explosion of mixtures of coal gas and air contained in a closed vessel. Experiments show that only 90 per cent of the coal gas is burnt by the time the maximum pressure is reached, and it is estimated that were it possible to check all heat loss and burn all the gas within the explosion period the maximum rise of pressure would be increased by 14 per cent in the case of a 15 per cent mixture of coal gas and air and by 31 per cent in the case of a 9.7 per cent mixture.

In the second section after-burning in a gas-engine cylinder is discussed. It is inferred that with normal ignition only about 70 per cent of the fuel charge is burnt at the moment indicated by the peak of the indicator diagram, and there seems little doubt that incomplete combustion ranks equally with increasing specific heat as a primary cause limiting the maximum pressures developed in gas engines. The distinction between inflammation and combustion is emphasized, and it is suggested that with normal ignition setting the maximum pressure occurs more or less in the neighborhood of complete inflammation. In strong mixtures which give vertical explosion lines in the indicator diagrams, the bulk of the after-burning appears to be completed in the early stages of the expansion stroke, owing to the fact that the rate of change of volume is small in this epoch. Consequently, in strong mixtures after-burning does not affect the thermal efficiency very much. In the case of

weaker mixtures giving sloping explosion lines the rate of change of volume after the maximum pressure is reached becomes fairly rapid, and after-burning continues for some considerable distance down the expansion line. The thermal efficiency is therefore considerably affected both on account of slow inflammation and on account of after-burning. The conclusion is reached that the defect of the actual efficiency of an engine from the ideal variable specific-heat efficiency is to be attributed mainly to heat flow from the working fluid into the cylinder walls when it is working on strong mixtures and mainly to slow inflammation and after-burning when it is working on weak mixtures. The possibility of speeding up after-burning is discussed and suggestions are put forward for a research directed to this end.

In the third section it is shown that the curve prepared by the British Association Committee on Gaseous Explosions connecting the internal energy of a typical gas-engine mixture with its temperature requires modification at the higher temperatures. Assuming the correctness of the curve at the lower temperatures, a modified curve has been prepared which gives at 2000 deg. cent. a value for the internal energy about 4 per cent less than that given by the British Association Committee.

In the fourth section it is shown that the heat loss in any given engine working at a constant speed may be calculated approximately by means of the formula $KT^2_{max.}$, in which K is a constant for the given engine and $T_{max.}$ the absolute maximum temperature developed on explosion of the charge. It is also shown that, although the heat loss by conduction per unit area of wall surface at any given gas temperature is independent of the dimensions of the cylinder, the loss by radiation per unit area increases greatly with the dimensions. The reason for the unreliability of the large gas engine is thus made clear. (*Engineering*, vol. 113, no. 2932, Mar. 10, 1922, pp. 281–284. 2 figs., *tA*)

Heavy-Oil Two-Cycle Garuffa Motor. Description of what is claimed to be an extra light heavy-oil aeronautical engine based on the Diesel cycle. It is stated that it can be built with stationary cylinders disposed starwise, in V or in a single row. The type specially designed for aeronautic use consists of nine cylinders starwise and it is said that one such motor worked on the testing stand for 28 hours and without interruption, notwithstanding the fact that the weight of the motor is only 800 gr. (1.76 lb.) per horsepower.

The Garuffa motor has no valves but is provided with ports, intake and exhaust, which are opened and closed by the piston. Fuel injection is secured by a direct-acting atomizer. It begins a little before the piston reaches the dead center and continues for a little while afterward, thus giving a cycle composed of an explosion phase followed by a gradual combustion phase. The atomizer is designed with the idea of breaking up the liquid as much as possible, partly by means of passing it through a series of capillary holes in the cylinder and also by applying pressure directly to the fuel. In this case the single pump gives a gage pressure of from 7 to 10 atmos. in all the cylinders. (*L'Aerophile*, vol. 30, no. 3–4, Feb. 1–15, 1922, pp. XVIII–XX, 4 figs., *d*)

Some Aspects of Air-Cooled Cylinder Design and Development, S. D. Heron. An extensive paper reviewing some of the salient points arising in the design and development of the modern high-output air-cooled cylinder, and based to a large extent upon the work of previous investigators.

The problems of an aircraft cylinder of approximately 40 b.hp. are dealt with primarily, but some aspects of automobile-engine cylinder design are considered.

The first point treated is the heat to be dissipated, this being followed by a consideration of how to secure an even temperature distribution in the various parts of the cylinder. Cooling by a direct air blast and by conduction is discussed, the importance of removing the heat from the cylinder at the point where it is given to the head, the ports and the barrel being particularly emphasized. The effects of mixture strength and cooling-air supply upon the cylinder temperature are commented on, the text being supplemented by a number of tables. Methods of finning different forms of cylinder, the cooling surface required; the effect of the compression-ratio on the output, fuel consumption and wall temperature; cylinder materials; types of cylinder, with a summary of the advantages and disadvantages of the different forms of construction, valve-seat inserts in aluminum cylinder heads; exhaust-valve cooling; and valve gears, all receive attention.

The conclusions reached are that (*a*) successful air cooling is not limited to 50 b.hp. per cylinder; (*b*) fragility of the fins is a disadvantage of air cooling; and (*c*) the compromises necessary in the design of air-cooled cylinders have been made at the expense of the cooling efficiency.

The effect of the position of the spark plugs on the power output and the fuel consumption is discussed in an appendix and the use of two spark plugs located on a common horizontal axis that passes through the vertical axis of the combustion chamber in such a position that neither plug can project a flame wave against the exhaust valves is commended. The influence of gas velocity through the valves on the performance of an air-cooled engine is the subject of a second appendix. In this, as throughout the paper proper, numerous illustrations and tabulations of test results supplement the text. (*The Journal of the Society of Automotive Engineers*, vol. 10, no. 4, pp. 231–260, 35 figs., *etA*)

MACHINE PARTS

Tangent Rack Gearing

Hotchkiss-Taylor System of Tangent Rack Gearing. Investigation of system of gearing in which the rack is arranged in a plane tangential to a cylinder as shown diagrammatically in Fig. 9. The basic gear form of this system is a ground wheel, the teeth of which are involute curves in a plane normal to the axis of the crown wheel. Fig. 9 shows the crown-wheel involute-curve teeth and to the left an extension representing the tangent rack of similar tooth profile.

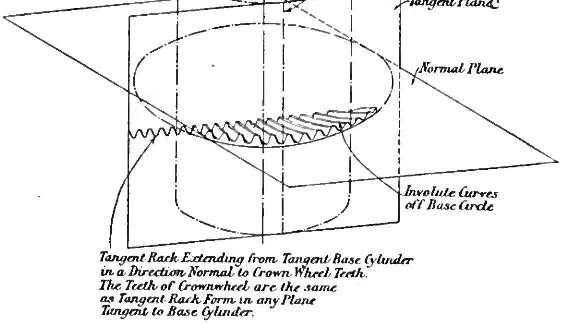

Fig. 9 Hotchkiss-Taylor System of Tangent Rack Gearing

The original article shows modifications of the same system, for example, the spiral bevel and the double helical bevel, and it is said that it is possible to produce bevel sets with non-intersecting axes.

In the tangent rack system any gear whether cylindrical or conical can be meshed with any other provided it is conjugate to the basis tangent rack crown wheel, and base circle or normal pitches are equal. The end thrust with this system of gearing is small in the case of crown wheels, and practically nil in the case of the pinions, being due to the rack-section pressure angle only, so that heavy thrust bearings are not required. For tangent involute worm gears it is desirable to employ a fairly high pressure angle, in order to mitigate the interference which would otherwise occur arising from the curvature of the crown-wheel teeth. The spiral of tangent bevel gears is involute, and in action the load component of the torque is applied tangentially to the base cylinder at any position of engagement of the pinion teeth with the crown wheel. (*Engineering*, vol. 113, no. 2935, Mar. 31, 1922, pp. 400–401, 10 figs., *d*)

Manganese Bronze for Valve Stems, Wm. R. Conard, Mem. Am.Soc.M.E. The author believes that the best bronze for valve

stems is that which has the characteristics of high yield point or elastic limit, moderate ductility, and high ultimate strength, but not more than 100 per cent higher than the yield point.

This is comparatively easy to obtain as there are bronzes which have a yield point of not less than 40,000 lb. per sq. in., an ultimate strength of 60,000 to 70,000 lb. per sq. in., an elongation percentage of 10 in 2 in. and a reduced-area percentage of 10.

To overcome the causes of failures of valve stems as far as possible, the calculations for stem diameter should be based on the following:

Allowance for the fact that the metal at the base of the thread does not have as great a strength as near the surface or the top of the thread; a further allowance for the use of tools for operating, which will exert greater stress than the usual tool used; together with allowances for friction due to corrosion or sediment in the water, and other factors mentioned earlier, of weight of mechanism, friction of gates and seats in operation, and friction in stuffing box, control the area at the base of the thread, and also that a liberal allowance should be made the governing feature for factors of safety, and the metal should have a high yield point, a fairly high ultimate strength, and moderate ductility.

In order that the physical qualities of the bronze may be known and kept uniform, it is very important that frequent tests be made. The proper way to get the pieces for testing so as to have them as truly representative as the stems themselves, is, where the stem is cast and large enough to do so, to have the piece for testing cast attached to the actual stem, and where the stem is of a size to make this impossible the test piece should be cast in the same heat and in the same flask as the stems. In the case of hammered or forged stems, the test piece should be a prolongation of one end of the stem reduced to a cross-section that will show a close approximate of the metal in the stem itself. It is unnecessary to go into the details of the methods of making the physical tests.

For smaller and medium-sized valve stems up to and including those for, say, 24-in. valves, a cast stem is entirely proper, but for stems for valves 30 in. and larger they should be of forged manganese bronze. Forging adds very little to the cost and adds some to the physical qualities, but its main value lies in that the forging on stems of heavy cross-section makes the metal homogeneous and of uniform texture throughout, makes a perfect metal for the threads and eliminates the uncertainties that are apt to be present in the case of large castings, where the central section is subject to different cooling stresses than the outer section. (*Journal of the New England Water Works Association*, vol. 36, no. 1, pp. 32–36, and discussion pp. 37–39, *p*)

MACHINE SHOP

Hand- and Machine-Lapped Surfaces as Seen Through a Microscope. The production of highly efficient lapped surfaces is of considerable importance in precision-gage manufacture. From an investigation carried out by a manufacturer of gages by means of photomicrographs it would appear that there is a material difference between hand-lapped and machine-lapped surfaces; the latter not only appear to be smoother but the scratches on machine-lapped surfaces are short and either parallel with the axis of the plug or slightly inclined. On the contrary, scratches on hand-lapped gages extend diagonally around the work, due to the use of ring lap which is given a traversing movement. In lapping machines the finer surfaces are obtained by performing the lapping operation between two flat cast-iron plates having very true surfaces and operating in such a way that the plugs receive a combination of rolling and sliding action.

Among other things, it is stated in the article that lately a modified process has been developed for lapping of true cylinders between flat plates, of which no details are given though it is stated that by this means a number of cylindrical gages for other parts are lapped simultaneously and by systematically and repeatedly transposing them and averaging the errors the entire lot is finished to a true cylinder form to within, say, 0.00001 in. or less. (*Machinery*, vol. 28, no. 8, Apr., 1922, pp. 638–639, 6 figs., *dc*)

Production Figures on Locomotive Fusible Plugs. It is said that in England the capstan lathe was recently successfully used in connection with the production of locomotive-boiler fusible plugs. The special-tool layout for these plugs is shown in the original article and comprises, among other things, a starting and facing drill, a straight-flute drill, a double-knee tool holder with pilot, a taper boring bit and a special taper running steady. The machine is fitted with a chasing-arm attachment and the sequence of operation is as follows:

Grip plug on square end with special jaws in two-jaw chuck.

Start drill and face end of casting to length, with special starting drill and holder.

Drill-tapping hole with straight-flute drill in drill chuck.

Turn external diameter of plug (parallel) to remove scale, with double-knee tool holder, cut being steadied by plain pilot fitting in hole already drilled.

Open out end of hole with taper boring bit.

Steady with special taper plug in standard running center steady, and form external diameter to correct taper with wide form tool on rear of cross-slide.

Retain running center steady in operative position and cut thread with chasing tool in swing-over chasing arm. Approximately six cuts are necessary to cut the full thread.

Tap center hole, using $^5/_8$-in. tap in standard releasing tapholder.

Remove from chuck.

The maintainable production time on this sequence of operation is 1 min. 15 sec. per plug, or 48 plugs per hour. It should be realized that this production time applies to the complete machining of the plug from the rough casting, screwing it both internally and externally to the usual standard gages, so that no further machining work is necessary. (*British Machine Tool Engineer*, vol. 2, no. 14, Mar.-Apr. 1922, p. 452, *p*)

MEASURING APPARATUS (See Railroad Engineering)

MOTOR-CAR ENGINEERING

Nitrogen as a Tire-Filling Material. The Roland Machine Construction Co. of Berlin has experimented with rubber tires filled with pure oxygen and find that they deteriorate with great rapidity under these conditions. As this tended to point to the possibility that it was oxidation phenomena that caused the destruction of the tires, experiments were carried on in the opposite direction, namely, with oxygen-free, that is, inert materials, in particular, nitrogen as tire filler. The results have been very interesting. Nitrogen-filled tires maintain their hardness for over a year in cars driven over thousands of miles on open roads. The loss of nitrogen proved to be surprisingly small and the state of the rubber far better than in air-filled tires. Similar tests have been carried out by the Continental Caoutchouc and Rubber Co. (German) and have given substantially similar results. The explanation offered by Prof. K. A. Hoffmann is based on the sensitiveness of rubber to oxygen and particularly ozone. A contributing factor is the oxidation of the sulphur contained in vulcanized rubber.

It would appear that if the advantages from filling tires with nitrogen instead of air are as great as would follow from the above described experiments, the question of added cost would not be of material importance. (*Motor und Auto*, vol. 19, no. 5, Mar. 15, 1922, pp. 73–74, *epA*)

Mercedes Car with Supercharged Engine. In the Targa Floria race held on April 2, 1922, on the island of Sicily, the Mercedes car covered 269 miles in 6 hr. and 50 min. at an average of 39.3 miles an hour. The speed does not appear to be large unless it is taken into consideration that the race was around a mountain side with a number of bends and holes, testing the endurance of both cars and drivers to the utmost.

The Mercedes car used a supercharger about which very few particulars were given out at the race. The engine had four valves per cylinder driven by a couple of overhead camshafts in aluminum housings. The camshaft drive was by vertical shaft and bevel gearing at the rear, with the magneto also at the rear, and the spark plugs placed in the center of the cylinder head. The design makes it possible to throw the supercharger into and out of engagement as desired. Nothing definite has been published about the power

output of the engines, but the author learned on reliable authority that they run up to 5000 r.p.m. (*The Autocar*, vol. 48, no. 1382, Apr. 15, 1922. The entire article covers pp. 622–628, illustrated; the part referring to the Mercedes engine described in the abstract, pp. 627–628 with no illustrations, d.A)

POWER-PLANT ENGINEERING (See Also Air Engineering)

Setting Valves of Marine Engines by Elliptical Diagram

Setting Valves by Elliptical Diagram, Arthur O. Gates. Description of a method employed on marine engines. The common method of setting valves on marine engines after an overhaul is by the use of rods or trams which have marked upon them the positions of the valve points and the openings into the cylinder casting. One of these rods is held upon the outside of the cylindrical casting; the other is set upon the end of the valve at some designated point. The engine crank for that cylinder is brought to dead center and the valve adjusted to the designated lead. The process is clumsy as the trams may be easily lost and there is always a chance for uncertainty in the measurement and adjustment of the lead.

In January, 1918, the U. S. S. *Marblehead* was released from the Mare Island Navy Yard after a short overhaul of her engines which necessitated resetting of the valves. On the run down the California coast it was found that the valves were not properly set and the writer was assigned to the duty of planning and making the proper changes. He did this by the application of the elliptical diagram.

The diagram given in Fig. 10 is for one low-pressure cylinder and is reduced to about half size. In the original plotting the actual movement of the valve was shown at all points, while the piston movement was plotted to scale. After the plot was made the distance that the valve was open at the top when in its lowest position for one block setting was measured upon the diagram and a horizontal line drawn through this point. The valve traveled upward this amount and closed the port. This is the point of cut-off. The valve continued to travel upward and after a distance of about $1^{1}/_{2}$ in., as may be calculated from the drawing of the valve and ports, the port to the bottom end was closed; this determined the compression point of the bottom end. Travel continued for about $1^{1}/_{8}$ in. and the release of the top end occurred. Then, as the valve traveled upward $1^{9}/_{16}$ in. further, steam was admitted to the bottom cylinder and the valve continued upward until the port opening of the bottom end became $2^{3}/_{4}$ in. by the old setting and 3 in. by the new. These were measurements calculated from the drawing as there was no way (or need) to get under the valve without dismantling the engine.

Following the valve on its return stroke, on closing the port for cut-off of the bottom cylinder the valve had of course traveled back the $2^{3}/_{4}$ in. or 3 in. mentioned above; then down $1^{9}/_{16}$ in. to compression of the top end; then down about $1^{1}/_{8}$ in. to release of the bottom cylinder, then $1^{1}/_{2}$ in. down to admission to the top end, and on to the end of the stroke of the valve, which gave a full valve opening of $2^{3}/_{16}$ in. by the old setting, and $1^{15}/_{16}$ in. by the new.

The other curves were obtained by changing the block setting, screwing it in the number of inches indicated by the number on the curve. The valve gear of this engine was of the Stephenson link type using the double bar link of a type common in marine practice, and the control of the expansion of the cylinder was obtained by adjustment of the position at which the rod connecting the Stephenson link was secured to the reversing gear. An adjustable block at this point determined the point of application of the eccentric motion to the valve stem.

From these diagrams indicator cards may be constructed. Among the points brought out by this diagram is the relative unimportance of lead. With a new setting the lead at the top end (bottom of diagram) measures about $^{5}/_{16}$ in. and for the bottom end $1^{3}/_{16}$ in.

The author believes that this diagram could be applied to the settings of valves of a Corliss engine by plotting the movement of the wristplate measured along the arc of the pins of the rods connecting to the valves; on some engines two sets of diagrams would be required—one for the steam valves and one for the exhaust valves. The theoretical indicator diagram which has been added below the valve diagram is intended to show how the adjustments would affect the points in the card, and without regard to the pressures, clearances and distribution between the different cylinders. (*Power Plant Engineering*, vol. 26, no. 8, Apr. 15, 1922, pp. 410–413, 1 fig., p.A)

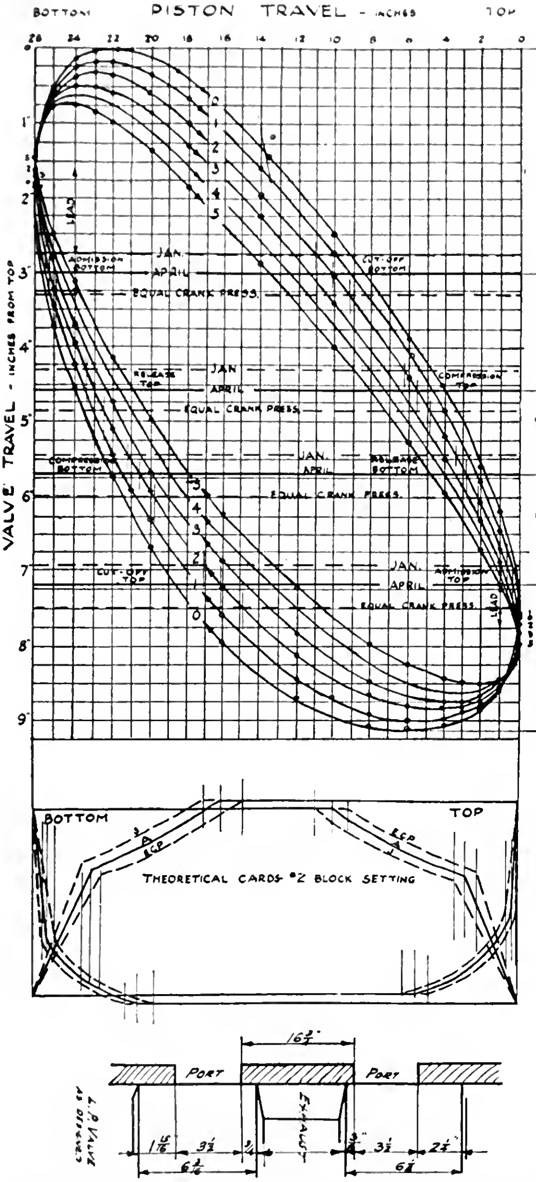

Fig. 10 Elliptical Diagram Used in Setting Engine Valves

PUMPS

Tests on Impact Losses of Water Jets

Impact Losses of Jets, J. J. Burnell. Description of tests and experiments on water jets from centrifugal pumps carried out at the pumping station of the State Rivers and Water Supply Commission of Victoria, Australia. The article describes fully the method of carrying out the tests.

The first set of experiments was designed to determine the loss of kinetic energy in the jet due to varying deviations. The results obtained show that the loss of velocity due to sudden deviation of the jet through any angle up to 90 deg. is practically negligible. The greatest loss of kinetic energy occurs between 20 and 25 deg.

deviation and is of the order of 2 per cent only. It was observed, however, that for angles of deviation of 10 deg. and upward a certain portion of the total flow took place along the vein in the direction opposite to the main flow. The results are given in Fig. 11.

The three curves in Fig. 11, in which the proportion of back flow is plotted against the deviation of the jet in degrees, show a curious inflection extending from 15 to 30 deg. Such an inflection might be suspected as due to experimental error were it not very similar in all three curves, and did not correspond almost exactly to an inflection in the curves purposely shown below, in which the kinetic energy after impact or deflection is similarly plotted against the deflection of the jet in degrees.

Formulas for the relative proportion of back flow to forward flow are given in the original article, and are compared with the results obtained by Prof. A. H. Gibson. (Hydraulics and Its Applications, p. 368.)

While the experimental results do not fall exactly on this curve they do follow it more or less closely, and conform generally to the law it expresses. From 0 deg. to 10 deg. there is considerably less back flow than indicated by the theory; exact agreement occurs at about 15 deg., beyond which the back flow is always greater than indicated by the theory. Above 15 deg. the discrepancy is greater the greater the head. In practice, however, the results between 0 deg. and 15 deg. are those of greatest importance. The proportion of back flow up to 10 deg. deflection is so very small—about one part in 1000—as to be quite negligible in ordinary practice. For 15 deg. it may be taken as 1.8 per cent.

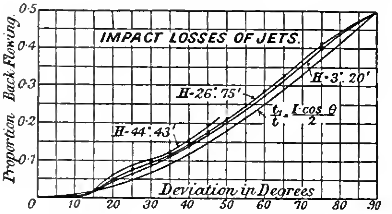

Fig. 11 Impact Losses of Water Jets Due to Deviations

Friction losses in bends were also investigated and were in general found to be quite small. (Paper before the Melbourne Division of the Institution of Engineers, Australia, Oct. 26, 1921, abstracted through *Engineering*, vol. 113, no. 2935, Mar. 31, 1922, pp. 404–405, 4 figs., *e*)

RAILROAD ENGINEERING (See also Machine Shop and Varia)

Studies on the Design for a 150-Lb. Rail Section, W. C. Cushing. The crux in rail design is the width and depth of head necessary to perform its work with safety and economy. There are two sets of conditions which determine the designs of rail sections, the sections being known as types RA-A, and RA-B. The one set of conditions is heavy tonnage carried in a territory of crooked alignment and steep grades, while the other set is centered in territory with better alignment and grade with the duty of carrying traffic of more moderate tonnage.

After all rail design had been brought to these two general types, the Rail Committee of the American Railway Engineering Association, after years of study, succeeded in having the set of designs known as the RE rail sections accepted as recommended practice, with weights varying from 100 to 140 lb. Lately a 150-lb.-per-yard section has been designed and recommended to the Rail Committee for presentation to the Association. While it has not yet been considered by the Rail Committee, it is of interest.

It has been proved many times that a heavy deep head is necessary for bearing safely and economically all heavy tonnage in territory of crooked alignment and steep grades. This has been confirmed practically by tests on the Pennsylvania Railroad. The first thing, therefore, to decide upon is the quantity of metal for the head deemed essential for carrying the load-bearing relation to wheel thread and allowing for considerable wasting away of metal before loss in strength requires removal. It is then necessary to decide upon the suitable thickness of base to avoid fractures and make a proper balance of metal with the head so as to render the problem of rail straightening easier by a medium punishment of the metal. It is next desirable to have proper relation between the thickness of web and its height in order that the column should be suitably proportioned.

Actually, the practice of the companies principally in the northeastern part of the country with great density of traffic carried over crooked alignment and steep grades leans toward rail design with heavy head and moderate height, while the western and southern companies having less dense traffic and larger percentage of tangent alignment with easy curves favor the thin head and great height.

As regards the cost per mile per unit of weight (10,000,000 tons) of traffic borne by the different weights and sections of rail, there is no reliable information, but from careful observations it has been estimated that the 130-lb. rail on the Pennsylvania System in its heavy-curvature districts outlasts by $2^1/_2$ times the 100-lb. section, and is worth 23 per cent more in reduced maintenance.

The conclusion to which the author arrives is that the time has not come yet for making any change in the present RE sections, especially as the 100-lb. and 130-lb. sections are now rolled. (Paper before the Annual Meeting of the American Railway Engineering Association, abstracted through *Railway Review*, vol. 70, no. 13, Apr. 1, 1922, pp. 447–449, 3 figs., *g*.—The author is Engineer of Standards, Pennsylvania Railroad System)

Test of Siphon Locomotive on Spokane International Railway. The Spokane International Railway in operation over its main line has to deal with conditions of local work and severe grades of such a character that it proved to be difficult to maintain the schedule with 10-wheel locomotives having cylinders 19 in. by 24 in. and 22,000 lb. tractive effort handling 5-car trains. This situation is still more aggravated by the poor quality of the coal and the limited grate area.

In an effort to remedy these conditions the railroad decided to install a Nicholson thermic siphon (Compare Mechanical Engineering, March, 1919, p. 284) on one of these passenger locomotives and to test this locomotive in comparison with another locomotive of the same class having a plain firebox.

The original article states the main reasons why the thermic siphon was selected in preference to other devices, among these factors being its ready adaptability to the locomotive and low maintenance charges, since the siphons become virtually a part of the firebox and necessitate no repair work outside of the ordinary firebox maintenance. Moreover, the application of this device has proved to be a relatively inexpensive means of increasing locomotive capacity and efficiency. The original article gives some data on the method of applying a single thermic siphon to the narrow firebox of the 10-wheel type locomotive.

The results are given in the original article in the form of curves and tables. From these it would appear that the application of the thermic siphons increased the tractive effort and cylinder horsepower, the former from 22,000 to 31,160 lb. and the latter from 1202 to 1264 hp. In addition to this, decidedly better firebox and boiler conditions have been obtained. The increased boiler and cylinder capacity of the siphon-equipped locomotive made it possible to handle the same train with greater ease, while the additional heating surface and improved water circulation caused by the siphon made a marked improvement in the steaming capacity of the locomotive. Maximum steam pressure was maintained at all times and the boiler was fully supplied with water during all of the runs with the siphon-equipped locomotive, while with the non-siphon locomotive it was necessary to trade water for steam in hard places. The coal consumption per sq. ft. of grate area was reduced to 133 lb. as compared with ordinary consumption which frequently exceeded 160 lb., and as a result of these tests the Spokane International Railway has ordered siphon equipment for a freight locomotive, which will enable the railway to increase the diameter of the cylinders on this locomotive 1 in., thus materially increasing the tractive effort and cylinder horsepower. (*Railway Review*, vol. 70, no. 15, Apr. 15, 1922, pp. 522–524, 3 figs., *cc*)

Ramsay Condensing Turbine Electric Locomotive. The locomotive was built for the Ramsay Company at the works of

Sir W. G. Armstrong, Whitworth & Co., Ltd. In this locomotive a condenser of novel form is applied in conjunction with the steam turbine. Superheated steam is expanded down from boiler pressure to a vacuum of 27½ in., the condensate being drawn off from the condenser by a rotary extracting pump and returned to the hot well, from which a feed pump delivers water into the boiler, thus completing the cycle.

The front engine, both as regards the boiler and underframe, differs but little from accepted locomotive practice, except that the reciprocating engine is displaced in favor of a turbo-generator made by the Oerlikon Company, of Zurich. The main turbine is of the impulse pressure compounded multi-stage type, connected through a flexible coupling to a three-phase generator capable of sustaining a 25 per cent overload for half an hour. This generator is separately excited by an auxiliary turbine-driven direct-current generator. The three-phase generator supplies power to four three-phase slip-ring motors arranged in two groups on the front and rear parts of the locomotive, respectively. The two motors of each group are bolted to a common stretcher carrying a countershaft, to which the motors are geared. The power is then transmitted from the countershaft to the six driving wheels on each part of the engine by coupling rods in the ordinary manner. Each of these motors is capable of developing 275 hp.

The rear engine contains the coal bunker and cooling-water tank, as well as the condenser and its appurtenances. The condenser forms one of the novel features of the engine. It is of the evaporative type supplied with air by a fan at the rear of the engine. The steam tubes of the condenser are arranged in the form of a cage, which is caused to revolve in water at slow speed and through which the air is impelled by the fan in a radial direction over the tubes. A flexible pipe between the two portions of the engine connects the turbine exhaust to the condenser.

The boiler is hand-fired and is fitted for forced draft. The driver operates the locomotive by means of a master controller placed in the cab. (*The Engineer*, vol. 133, no. 3456, Mar. 24, 1922, pp. 328–329, 2 figs., *d*)

Dynamometer-Car Tonnage Tests, O. O. Carr. The article is based on an experience of several months on a dynamometer car engaged in carrying out tonnage-rating tests on the Illinois Central Railroad.

One of the conclusions to which the author arrives is that office ratings of engines are entirely unreliable. Actual test observations show that train-resistance formula calculations are at variance with different track conditions. For instance, an 85-lb. steel track laid 12 years and worn down pretty well on a gravel bed through a cut on a 26-ft. grade will stall an engine loaded to maximum, and yet the same engine will have no difficulty whatever in going over a 26-ft. grade, 90-lb. rail, rock-balanced bed, the difference being due to the greater track resistance of the former.

Among the important factors affecting tonnage capacity of freight trains are mentioned individual locomotive characteristics and personal characteristics of the engine crews, as well as the kind of cars and their loading.

A comparison of results shows false economy of reducing tonnage. There is no economy in giving engines a 100 per cent train over a 130-mile district where there are a number of heavy grades to contend with and keep a train on the road 14 or 15 hr., but it may be profitable to keep a train on the road 12 hr. with a 100 per cent loading if this can be done without impairing the coöperation of the train crew in getting over the road.

Large train loads mean not only decreased number of train units running in both directions but decreased number of locomotives to handle and maintain, enabling more expeditious train movement and a corresponding increase in the capacity of the railroads. (*Railway Review*, vol. 70, no. 13, Apr. 1, 1922, pp. 451–455, *pA*)

Water Treatment as Affecting Locomotive Performance, W. A. Pownall. This article is based on the experience of the author for the past ten years on the Wabash Railway, where he occupies the position of mechanical engineer. There soda-ash treatment is being used and favorable results secured.

As regards the cost of water treatment, the waste of fuel and water in blowing off is possibly the major part, but there is no guesswork as to this item of expense. On an ordinary division where the treatment averages 0.6 lb. of soda ash per 1000 gal. of water, the fuel waste in blowing off is approximately 1.1 per cent of the coal used, and the total cost of the coal and water wasted is about $0.026 per 1000 gal. The average cost between washouts will be less than this since very little blowing is done after washout until the concentration has reached the foaming point. Under ordinary conditions it is usually cheaper to blow out a boiler than to wash it out at the terminal, but the cost of blowing out is much more than offset by fuel saving from clean heating surfaces and by other attendent benefits.

The writer emphasizes the fact that it is very essential to the successful use of treated water to have the support of the enginemen.

Some practical suggestions as to the details of operation are offered in the original article. In particular, it is stated that on the Wabash the foaming point is reached when the concentration of dissolved solids is about 240 parts per 100,000. (*Railway Mechanical Engineer*, vol. 96, no. 4, Apr., 1922, pp. 191–192, *p*)

Steel Rails Embrittled by Welding Bonds. According to tests made by a private laboratory it was found that decided weakening of steel T-rails is produced by attaching electric rail bonds by welding.

On some lines of the Mexico City Street Railway System loss of exposed copper bonds by theft became serious enough to make a concealed bond desirable. A bond was therefore designed to fit under the standard splice bar passing around the bolts and was to be attached to the rail web by means of electric arc welding of the steel facing to the rail metal.

In tests made to determine whether this method of attaching a bond affected the strength of the rail, samples were submitted to comparative drop tests. In these tests the unbonded specimens broke on the third and fifth blow, where the bonded specimens drop on the first blow. Moreover, quite abnormal shapes of fracture resulted in the case of the bonded specimens. It is believed, however, that attaching the bond to the head or base of the rail by welding instead of to the web may not be injurious, owing to the more massive shape of the sections affected. (*Engineering News-Record*, vol. 88, no. 13, Mar. 30, 1922, pp. 524–525, 2 figs., *d*)

SPECIAL PROCESSES

The Manufacture of Brass Forgings, C. T. Roder. Description of a process which is also called die pressing or hot forging. The method of forging brass was initially developed in Germany and Great Britain about 1900. In this country it did not reach the stage of commercial-development until after the United States went into the war. The process requires the highest type of skill in the art of forging.

A brass pill or slug cut off from extruded rod is heated in a specially constructed furnace open at both ends to a cherry-red heat (approximately 1300 deg. fahr.), though the temperature varies with size and construction of the piece to be forged. The pill is then fed into the press. The ordinary small shapes (up to 4 in. in diameter) are forged under 400,000 lb. pressure; for larger pieces presses are used having capacities up to 600 tons. With the continuous operation of a press and a skillful operator one press can average from 5,000 to 10,000 forgings per day.

Small forgings of simple design where the metal does not have to flow far are produced in a single-acting press. Where the shape is very intricate and where it is necessary for the metal to flow over a long distance, double-acting presses are used.

Brass forgings are 80 per cent stronger than sand castings and show a tensile strength and yield point, respectively, of 55,000 and 28,000 lb. per sq. in. and an elongation of 30 per cent, though the writer knows of instances where forgings have been made with a tensile strength of 105,000 lb. per sq. in., this being accomplished by a special mixture of metals. Dimensions can be held to 0.005 in. on diameters and 0.010 in. on length, in addition to which the metal is easier to machine than sand castings.

The original article gives some practical suggestions as to die design and expresses a belief that the forging process will extend in its applications. (*The Iron Age*, vol. 109, no. 13, Mar. 30, 1922, pp. 857–858, 2 figs., *dp*)

STEAM ENGINEERING (See also Air Engineering and Power-Plant Engineering)

Laws of Similarity as Applied to Steam Turbines

The Size Factor in Steam Turbines. Laws of similarity have been found to be applicable to reciprocating steam engines and it is generally accepted that while the output of engines run at corresponding speeds increases as the square of the scale, the weight increases as the cube, and hence the weight per horsepower developed should increase directly as the cylinder diameter.

The corresponding law of similarity applies to steam turbines, with the distinction, however, that while in engine practice the dead weight carried by the shaft is commonly small compared with the load imposed by the steam pressures or by the inertia of the moving parts, in a steam turbine the bending stresses are entirely due to the weight of the rotor which increases as the cube of the scale. Hence, with geometrically similar rotors the bending stress on the shaft will increase in direct proportion to the scale, but as regards output the same rule applies as in the case of the reciprocating engine, namely, that at corresponding speeds the output increases as the square of the scale.

The effect of change of scale on the efficiency of geometrically similar turbines does not appear to have received much study as yet, and evidence is much less direct than is desirable.

A large turbine is not generally a replica of a small one to a larger scale, a condition of affairs for which commercial considerations are largely responsible. The cost of valves, governor gear, oil pumps, tachometers, gages and other accessories forms a far greater proportion of the total cost of a small turbine than it does of a large one. Some interesting information on this head was given in a paper read before the Rugby Engineering Society in 1913 by J. P. Chittenden, from which it appears that in the case of a turbine rated at 500 kw. the cost of accessories amounted to 45 per cent of the total. With an output of 10,000 kw. this figure was reduced to 30 per cent. Hence small turbines have in general been constructed with a lower ratio of blade speed to steam speed than large ones, so as to keep down the cost per kilowatt of rated output.

For this reason the data for a direct determination of the effect of size on the efficiency hardly exist. In actual fact the published test data for small turbines and for large ones plot down very fairly on the same efficiency curve, but this constitutes by no means conclusive evidence that the effect of size on efficiency is unimportant, since for the reasons stated the large turbines and the small ones correspond to different regions of the curve and are not therefore similar turbines run at equivalent speeds.

That the test results do in general plot down with fair regularity is very satisfactory from the practical standpoint as it simplifies the work of the designer, but it is not what would have been anticipated from general considerations, almost all of which would lead us to anticipate that the element of mere size should have a by no means negligible influence on turbine efficiency. For example, from the theory of dimensions it appears that in geometrically similar turbines run at corresponding speeds the waste of thermodynamic head in guide-blade and bucket friction should vary as d^{-n}, where n is unknown, but is in all probability a small positive fraction, and d denotes some characteristic dimension of the similar guide blades. In the actual practice of today, however, the dimensions of the guide blades and buckets hardly increase as fast as the diameter of the turbine, and this will tend to reduce the difference between the relative steam friction losses in large and in small machines.

The question of relative clearance losses is a difficult one. In general engineering work clearances vary rather as the square root of the scale than in direct proportion thereto, and if this rule held in steam-turbine practice the larger the machine the smaller proportionately should be the losses by leakage. On the other hand, if the main proportions of the machine were strictly geometrically similar, the deflection of the shaft would increase directly as the scale and the limiting value of the clearances to which it is practicable to work must be a fraction of the shaft stiffness. If we attempt to obtain further light on this matter by a comparison with experience, we are again confronted with the lack of data which are fairly comparative, since in general the smaller machine will have fewer stages, and thus be relatively shorter than the large one, and the stiffness of shaft increases very rapidly as its length is reduced.

The subject of waste of energy in disk friction and fan action is also discussed largely on the basis of a paper by Eskil Berg read in 1919 before The American Institute of Electrical Engineers. (*Engineering*, vol. 113, no. 2935, Mar. 31, 1922, pp. 395-396, editorial article, *g*)

TESTING AND MEASUREMENTS

New Theory of Tensile Strength of Metals

Tensile Strength of Plastic Metals, Dr. Friedrich Koerber. This paper presents a method for computing the tensile strength of plastic metals from the curve of "true" stresses. It also discusses the mechanism of the tensile rupture test and proposes a theory of tensile stresses based on an assumption of slip and torsion effects of crystalline elements in the metal. Confirmation of the theory is sought for in X-ray photographs.

In tensile tests it is usual to compute the load on the basis of the initial cross-section of the test piece. The tensile stresses $\sigma = P/f_0$ computed in this manner, however, increase with increasing load up to a certain maximum value for cold tensile strength, and then fall off up to the breaking load at which the test piece ruptures. On the left-hand side of Fig. 12 is shown the stress-elongation curve as usually plotted. In this process the cross-section of the test piece decreases practically uniformly over its entire length; it is only after the maximum load has been reached that local contractions occur.

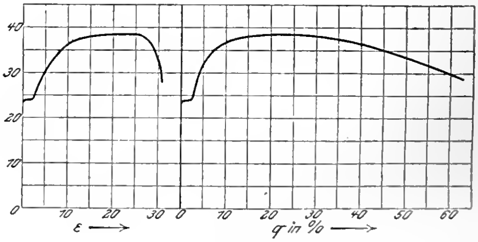

Fig. 12 Stress-Elongation and Stress-Reduction of Area Curves

On the right-hand side of Fig. 12 the variation of stress is shown for the entire test piece as a function of reduction of area at the thinnest obtaining section of the test piece. From such a curve it would likewise appear that the stress passes through a maximum value.

The stress values computed in this way do not, however, give a basis of measurement of the actual stresses produced in the test pieces by the load applied to it, and in particular it is difficult to express the physical meaning of tensile strength as the maximum load is being expressed in terms of a cross-section of test piece, which does not actually exist at the time when the maximum load is being applied.

A more complete idea of the state of stress in a material may be had by referring the load to the minimum area of cross-section in a test piece that may obtain at any given moment, which, in other words, means by computing the "true" stress $\sigma' = P/f$.

If the stress σ' obtained in this manner be considered in functional relation to the reduction of area, it will appear that in the region of the greater form variation of material these values lie very nearly along a straight line. This fact has already been observed before by the author and other investigators, and the author gives in the original article curves for pure iron-carbon alloys and technically pure copper, which illustrate the straight-line character of the stress-reduction of area curves.

In Fig. 13 the heavy line gives the ideal σ' curve. The point e shows the beginning of the reduction of area process. In the region of the greater plastic alterations of shape, the following law holds good: *The increase of stress is proportional to the alteration of shape of material expressed by the reduction of area.* If we select the initial area $f_0 = 1$, then the load or the stress σ referred to a unit of the initial cross-section of a material is a product of the "true" stress σ' and the area $f = (100 - q)/100$. While the cross-section f decreases gradually and in accordance with a straight-line law until it reaches a value of zero corresponding to a reduction of area $q = 100$,

the true stress σ' gradually rises from zero and, for the regions of greater stresses, follows likewise the straight-line law. From this it follows that the stress σ is equal to zero for those values for which σ' or f are equal to zero, and between these two values it passes through a maximum value σ_{max}. This particular value of tensile strength may be expressed by the formula:

$$\sigma_{max} = \left(\frac{\sigma'_0 + 100\,\alpha}{2}\right)^2 \times \frac{1}{100\,\alpha}$$

which permits computing the constants σ'_0 and α for the straight-line part of the $\sigma' q$ curve. The meaning of these constants may be seen from Fig. 13.

The parts referring to the theory of slip and torsion of the crystals in plastic metals cannot be reported here owing to lack of space. It is of interest, however, in view of the slip-interference theory proposed by Zay Jefferies and R. S. Archer, for which compare the abstract in Mechanical Engineering, August, 1921, p. 543 from *Chemical and Metallurgical Engineering* (vol. 24, no. 24, June 15, 1921, pp. 1057–1067). (Abstract from the Bulletin of the Kaiser Wilhelm Institute for Iron Research (Kaiser Wilhelm Institut für Eisenforschung) vol. 3, no. 2, in *Stahl und Eisen*, vol. 42, no. 10, Mar. 9, 1922, pp. 365–370, 8 figs., *etA*)

VARIA

Locomotive Construction by the British Government. The scheme for building locomotives by the Government originated with the Woolwich Shop Stewards' Committee (in America, Walking Delegates' Committee). After the Armistice an attempt was made to introduce commercial work into the arsenal production as a means to obviate unemployment.

Under this scheme all sorts of things, such as milk churns, medals, etc., were manufactured at the arsenal, the largest thing being, however, the manufacture of locomotives. There were initially no shops or machinery suitable for this and no officials who understood the business, nor was there any guarantee that the engines when manufactured would be purchased by the railway companies. Nevertheless, under the auspices of the Ministry of Munitions huge areas of existing factories at Woolwich were pulled down, machinery was transferred at great expense to other parts of the arsenal and the new plant was laid down at a period when both machinery and materials were at almost their highest price. The total expenditure in this connection is conservatively estimated at £500,000.

Shop managers who had no knowledge of locomotive manufacture were sent to railway engineering centers to obtain it. It took some time to organize the production and when the shops were ready the market began to fall. It is still falling owing to the cheapening of labor and materials, and English railway companies will not look at the engines at the prices the Government asks for them. At one time there was a hope that the locomotives could be sold to Russia until it was discovered that the gage was unsuitable for the railway systems in that country.

The result of this adventure in Government manufacturing is not encouraging. The Government has on its hands 45 locomotives it cannot sell; it has lost £900,000 in the business and has a further loss in view; it has a large plant of a very expensive character for which in the near future it will have no use; and the benefits to labor are more than doubtful. (*Daily Metal Trade*, vol. 12, no. 77, Apr. 19, 1922, p. 7, *g*)

Soundproof Partitions, F. R. Watson. Data of tests on transmission of sound through partitions, of interest in that, among other things, they present the theory of transmission of sound through a partition.

Sound may be transmitted from one side of a partition to the other in three ways: it may progress through continuous air passages; it may pass as an elastic wave length through the solid structure of the partition; or, by setting the partition in vibration, it may originate sound waves on the further side.

These actions are quite readily understood by remembering that sound consists of a series of compressions and rarefactions that progress rapidly through a medium without interruption unless they meet a new medium with a different elasticity or density. For instance, sound waves in air proceed without hindrance through air passages, such as ventilation openings in a partition. If, however, the passages are small in cross-section, as in the case of a porous material, the progress is hindered and a certain amount of absorption of the energy takes place, due to the friction set up between the vibrating air column and the sides of the pores.

In case the partition is impervious to air, the direct progress of the waves is interrupted. A thin partition is set in vibration and thus originates new waves on the side opposite the incident sound. For a thicker, more rigid partition the vibrations are smaller and a very considerable part of the energy is reflected. The transmission in this case takes place by compressional waves communicated to the solid material of the partition. The amount of energy thus transmitted is usually quite small.

In view of these considerations a soundproof partition should be as rigid and free from air passages as possible. For effective soundproofing of a group of rooms, the partitions, floors, and ceilings between adjacent rooms should be made continuous and rigid. Any necessary openings for pipes, ventilators, doors, and windows should be placed in outside or corridor walls where a leakage of sound will be less objectionable.

In case the sound is generated in the building structure, as the vibrations set up by a motor fastened to the floor, the compressional waves proceed through the continuity of solid materials. In order to stop them, it is necessary to make a break in the structure so as to interpose a new medium differing in elasticity and density. For instance, the vibrations of a motor may be minimized by placing a layer of hair felt, or similar air-filled material, between the supporting base and the floor. Where the machinery is quite heavy, footings may be made of alternate layers of asbestos, lead, and leather. Bolting through this material will reduce the insulation, because the vibrations in this case will pass easily through the bolts to the floor. The insulation should thus be left without any bridging over of the discontinuities. Air gaps in masonry will be effective if the air space is not bridged over at any point. A floor floated on sand, sawdust, or hair felt would approximate this condition. The edges of the floor should be insulated from the walls by felt or similar material.

Especial attention should be paid to the ventilation system. All effective soundproof constructions either omit entirely a ventilation system or else construct it in some special manner to avoid transmission of sound. In some buildings air is supplied and withdrawn from rooms by individual pipes that are small in diameter and extend without break from the air-supply chamber to the rooms. This results in considerable friction between the walls of the pipes and the air, with a resultant weakening of the sound waves. Without some efficient control of the transference of sound through the ventilation system it is a waste of effort to construct soundproof walls, double doors, and other contrivances for insulation.

When soundproofing a building all details should be considered with respect to the likelihood of transmission of sound. Each room, as far as possible, should be made an insulated unit by means of air spaces or air-filled materials that separate it from surrounding walls. Pipes and ventilators should be so installed as to minimize the chance of transfer of sound. Patent doors are now available that will close the door at top, sides, and bottom. In case a troublesome sound is generated in the room, it may be minimized by installing absorbing material on the walls.

The absorption of sound is an essential feature for soundproofing. Reflecting sound and scattering it still leaves it with energy. It must be absorbed; that is, converted into heat energy by friction, before it is eliminated as sound. This means that carpets, furniture draperies, etc., should be present, or if greater absorption is desired, hair felt or similar materials must be installed.

The insulation of sound is a complex problem and a successful solution is obtained only when all the possibilities of transfer of sound are anticipated and guarded against. (*University of Illinois Bulletin*, vol. 19, no. 28—same also as Bulletin 127 of Engineering Experiment Station, Mar. 6, 1922, pp. 1–178, 30 figs., bibliography pp. 77–78, *etA*)

Calculating the Efficiency of Boiler Seams, R. J. Finch. The article offers two tables worked out to shorten the labor necessary for finding the efficiency of a seam.

Table 1 shows what the author calls "value of rivet holes in plates;" in other words, the strength removed from the plate for various sizes of holes and thicknesses of plate. Table 2 gives the shearing value of iron and steel rivets for the different sizes of rivets shown in Table 1. Examples are given showing the rapidity with which the efficiency of seams can be calculated by the use of these tables.

As regards the design of seams, the author compares a decuple seam with a diamond seam. The latter under certain conditions and properly designed can have a theoretical efficiency as high as 98 per cent, but the author points out that there are certain drawbacks to a seam of too high an efficiency as well as to a seam requiring a wide side welt like the diamond seam. Among these drawbacks is the difficulty to properly design the brackets to hold locomotive accessories and still retain a proper efficiency for the studs attaching these brackets to the boiler shell. (*Railway Mechanical Engineer*, vol. 96, no. 4, Apr., 1922, pp. 193–196, 5 figs., *pA*)

WASTE PREVENTION

Utilization of Exhaust Steam from Electric Generating Stations, C. Ingham Haden. Discussion of prevention of waste of exhaust heat. The attitude which the author takes is that while the problem of lessening the waste of exhaust heat is a complex one, it is not impossible of solution.

The first main difficulty is to find a market for the heat; and if this is obtained the further difficulty arises of coördinating the loads, and from the point of view of economy he considers the heat load as a deciding factor.

Passing to the subject of super stations the author claims that the usual system of locating big generating stations at a supply of water for condensers is incorrect and it is the possibility of usefully employing exhaust heat that ought to be first considered in selecting their location. He further proposes the conversion of some of the existing generating stations which would be shut down under the superpower scheme but which are conveniently situated, into heat-distribution stations generating electric current as a by-product, and the linking up of such stations with the super stations.

While the superpower scheme considers generating stations from a comprehensive or national basis, it is equally important to consider the supply of heat upon a large scale. In practically all manufacturing localities there are industries that require heat in some form for boiling or drying purposes apart from the heating of the factories. Special arrangements would have to be made in such instances from a central source to supply steam at a suitable pressure, and this service could be maintained by live steam for continuous processes when the power plant was not running.

Utilization of exhaust steam for heat purposes, even at a pressure of 2 lb. per sq. in., would considerably reduce the electrical output and also render useless expensive condensing plants expressly designed to increase this output. The question resolves itself into one of economics, namely, would such a scheme be practicable and a paying proposition? The paper gives some practice of a typical district showing the probable heating and lighting loads, and finally describes installations which have already been carried out in England.

In the discussion which followed several references were made to American practice of district heating.

As an example of the author's method of calculation, the following may be cited. To take one example in London: a careful survey of the district within an approximate radius of half a mile from the generating station shows a possible heat load of 160,000 lb. of steam per hour, dealing only with buildings provided with existing installations for heating and hot-water supply, and those of suitable size for the steam service. If a further proportion of new buildings were erected within this area, this load could easily be doubled.

Taking the above figure as the demand, this would require additional steam at the station to allow for radiation losses, thus making the figure, say, 165,000 lb. of steam. With a boiler pressure of 150 lb. and superheat of 100 deg. fahr., and with generating plant designed for a back pressure of 60 lb. per sq. in. the steam consumption would be at the rate of about 115 lb. per kilowatt-hour, so that it would be possible to obtain power at the rate of about 1450 kw. Exhausting at 60 lb. per sq. in. there would still be some superheat in the steam, which would assist in reducing the radiation losses in the mains. The consumer would also benefit by any superheat remaining in the steam delivered to the calorifiers.

The net integrated load for the same district and buildings, allowing for average winter and summer conditions, amounts to 452,000,000 lb. of steam per annum. The gross income derived therefrom would amount to £90,400 if charged at the rate of 4 s. per 1000 lb., and the approximate number of electrical units obtained from the heat load to 3,930,000, which, at an average price of 2 s. 2 d. per unit, would amount to about £36,000.

The cost of the distributing mains, including all necessary work in the station and the formation of ducts, would depend upon the length of main required to serve the particular district, and the earning capacity of any main laid down would vary in like manner. Taking the same district, the total expenditure for engineers' work would be about £82,400, covering over 4 miles of streets, an average cost of £17,800 per mile, and an average earning capacity of £19,500 per mile.

The total load per mile is low, as one particular main a little over half a mile in length has an earning capacity of £23,800, equal to £37,000 per mile, showing that in districts where large buildings line the streets the income per mile would be still larger.

In addition to the distribution of heat by steam mains, it is possible in some cases to use hot water with advantage. (*The Journal of the Institution of Electrical Engineers*, vol. 60, no. 307, Mar., 1922, original paper pp. 265–271, discussion pp. 274–286, illustr., *pgA*)

WELDING (See also Railroad Engineering)

The Dependability of Cast-Iron Welding, G. O. Carter. In welding cast iron preheating and annealing are essential, and before welding the complete casting must be brought to a red temperature. This makes the welder's job strenuous; nevertheless, good men can be secured to do the work.

The article cites facts to show that good results can be and are being obtained with cast-iron welding, especially where this work has been properly systematized. The subject of preheating of castings is briefly discussed in a practical manner.

In the opinion of the author the difference between perfect success in some instances of cast-iron welding and failure in others lies in the various degrees of preparation for welding and treatment subsequent to welding. Cast iron not prepared by adequate preheating is apt to crack, and the crack does not always take place at the weld. For best results, the entire casting should be at a red temperature, though there are cases where partial preheating is sufficient. (Paper read before the Cleveland Section of the American Welding Society, abstracted through *The Iron Age*, vol. 109, no. 14, Apr. 6, 1922, pp. 928–930, 8 figs., *p*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society.

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A.S.M.E.

Research Résumé of the Month

A—RESEARCH RESULTS

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a resume of research results with formulas or curves where such may be readily given, and to report results of non-extensive researches which in the opinion of the investigators do not warrant a paper.

Bearings A1-22. FRICTION AND CARRYING CAPACITY OF BALL AND ROLLER BEARINGS. The experiments which are recorded in this Technologic Paper No. 201 were carried on at the Bureau of Standards by H. L. Whittemore, mechanical engineer, and S. N. Petrenko, assistant mechanical engineer. Their purpose was to determine the maximum safe load and the static friction under load of ball and flexible roller bearings.

Tests were made on balls of 1.00, 1.25 and 1.50 inches diameter in grooved races and on rollers 1.25 inches in diameter and 5.25 inches long in flat and cylindrical races.

The total deformation and area of contact of bearings and races were measured and compared with Hertz's theory.

Conclusions: 1 The results agree roughly with Hertz's theory. The differences are ascribable to inhomogeneity of the material.

2 The ratio of friction to load is practically constant and equal to 0.00035 for all three sizes of balls up to a "critical" load, which varies with the diameter of ball: 1300 pounds for 1.00-inch, 1700 pounds for 1.25-inch, and 2200 pounds for 1.5-inch balls.

3 A similar "critical" load, 25,000 pounds, was found for the roller bearings with a ratio of friction to load equal to 0.00075.

4 This "critical" load at which the friction began to increase more rapidly was in all cases lower than the safe load as determined by permanent deformation and as calculated from Stribeck's law.

The complete paper may be purchased from the Superintendent of Documents, Government Printing Office, Washington, D. C. Price 10 cents.

Cables and Ropes A1-22. TEST OF MANILA ROPE. The results of some tests of manila rope which had been conducted at the Bureau of Standards by Ambrose H. Stang and Lory R. Strickenberg are reported in Technologic Paper, No. 198. This paper summarizes the results of tensile tests of 368 specimens of manila rope. Most of the material was submitted on purchase orders for Government departments. They were all 3-strand, regular lay manila rope having diameters from $^1/_2$ in. to $4^1/_2$ in.

A summary of the results is given in tables and graphically. A formula is given for determining the average breaking load as a function of the diameter of the rope. The test results cover sufficient range and show such consistency that it is believed that the formulas may be used safely for 3-strand, regular lay manila rope of the sizes indicated. The ropes showed a continually varying modulus of elasticity and no well-defined proportional limit. This paper may be obtained by addressing the Superintendent of Documents, Government Printing Office, Washington, D. C. Price per copy 5 cents.

Electrical Communication A2-22. HIGH-FREQUENCY RESISTANCE OF INDUCTION COILS. See *Electricity, General A1-22.*

Electricity, General A1-22. HIGH-FREQUENCY RESISTANCE OF INDUCTION COILS. On account of the importance of inductance coils in radio communication, careful studies, both theoretical and experimental, have been made at the Bureau of Standards on capacity effects and other effects in inductance coils at radio frequencies. Some of the results of these investigations are contained in a new publication, Bureau of Standards Scientific Paper No. 430, The High-Frequency Resistance of Inductance Coils. In this paper a formula for the resistance of an inductance coil is derived which takes into consideration both the skin effect and the capacity effect for the case of a short single-layer solenoid, and the results of experiments are given which check this formula. Other more general formulas for current distribution and resistance are also derived.

A copy of this paper may be purchased for 5 cents from the Superintendent of Documents, Government Printing Office, Washington, D. C.

Foundry Equipment, Materials and Methods A1-22. MOLDING SAND RECLAMATION. The Committee on Molding Sand Research through the courtesy of the American Steel Foundries Company has prepared a digest of the sand reclamation work carried on by the engineering staff of the A.S.F.

Because of the scarcity of steel-molding sand of the best quality and the problems arising from having to dispose of large quantities of refuse sand, this company has carried out an extensive investigation of methods of reclaiming the good material which is usually lost whenever the so-called refuse sand is thrown away. After experimenting along different lines and thoroughly going over methods employed in other plants, a process of reclaiming old sand called "centrifugal scrubbing" was developed.

The report covers the theory of sand reclaiming, centrifugal air-scrubbing process, cost of reclaiming sand by the latter process, and a description of the proposed sand-reclaiming unit. Address Alfred D. Flinn, Chairman of Division of Engineering, National Research Council, 29 West 39th Street, New York.

Fuel, Gas, Tar and Coke A8-22. COAL AND COKE MIXTURES AS WATER-GAS GENERATOR FUEL. The scarcity of high-grade coke and the great rise in price of all grades of coke have made it almost necessary for some gas companies to consider the substitution of bituminous coal for coke as generator fuel, even though grave difficulties were expected in maintaining the capacity of the plant with the new fuel.

The experiments conducted at Streator, Ill., in 1918, in operating a 6-ft. set 6 to 7 hours a day did not solve some of the important questions in the use of coal fuel, namely, the effect of a stand-over period on capacity and possibilities in the use of the blow-run method of operating with mixed fuels, coal and coke. The chief purpose of this paper, therefore, is to present information bearing on these problems and the results obtained during six weeks of experiment at Davenport, Iowa, using mixed generator fuel with the blow-run method of operating. Data are included on the behavior of the various fuels used in the generator, the clinker conditions, the use of fuel high in ash, and on the use of coal high in sulphur.

This pamphlet which consists of 32 pages and is fully illustrated was prepared by W. W. Odell and is known as Bureau of Mines' Technical Paper 284. It was, however, prepared under a coöperative agreement with the Illinois State Geological Survey and the Engineering Experiment Station of the University of Illinois through its department of Mining Engineering. Address Superintendent of Documents, Government Printing Office, Washington, D. C. Price per copy 10 cents.

Glue A1-22. COPPER SALTS IMPROVE CASEIN GLUE. It has been found that copper salts added to casein glues greatly increase their resistance to moisture and also make them more durable when exposed to the action of molds and fungi. Casein glues containing copper are nearly as moisture-resistant as blood albumin glues.

In the preparation of copper-casein glue at the Forest Products Laboratory, 2 to 3 parts by weight of copper chloride or copper sulphate are dissolved in about 30 parts of water and are added to every 500 parts of the ordinary casein, lime and water-glass glue. The copper solution is poured into the glue in a thin stream. The violet-colored lumps formed at first by the coagulation of the glue by the copper solution are reduced by stirring vigorously for about 15 minutes, and a smooth violet-colored glue results. It is necessary to add the copper salts after the other ingredients are thoroughly mixed, in order to obtain beneficial results. Copper added to the casein before the lime and water glass is ineffective.

Glues containing little lime are especially improved by the addition of copper. A low-lime glue with copper may be as resistant to moisture as a glue with more lime in it, and copper does not shorten the "life" or period of workability of the glue so much as more lime would. Address the Forest Products Laboratory, U. S. Forest Service, Madison, Wisconsin.

Iron and Steel A1-22. THERMAL STRESSES IN CHILLED-IRON CAR WHEELS. See *Railroad Rolling Stock and Accessories A1-22.*

Petroleum, Asphalt and Wood Products A4-22. SPECIFICATIONS FOR PETROLEUM PRODUCTS. A set of specifications for petroleum products have been officially adopted by the Federal Specification Board for the use of the various departments and independent establishments of the Government. They contain specifications for (*a*) various grades of gasoline, (*b*) naphthas, (*c*) burning oils, (*d*) fuel oils, (*e*) lubricants of all kinds. These specifications are printed in full as Technologic Paper No. 305 of the Bureau of Mines. Address H. Foster Bain, Director, Bureau of Mines, Washington, D. C.

Railroad Rolling Stock and Accessories A1-22. THERMAL STRESSES IN CHILLED-IRON CAR WHEELS. For over half a century most of the freight cars in this country have been equipped with chilled-iron car wheels. These wheels have given general satisfaction, even under the present existing conditions of greater speeds and increased stresses due to the use of heavier wheel loads. It has been observed, however, that failure of chilled-iron wheels occur occasionally at the foot of long, steep grades, and the greatest cause of such failures appears to be the heating of the tread by the prolonged application of the brake shoe.

A method was developed at the Bureau of Standards for testing car wheels in the laboratory under conditions approximating severe service. The wheels were heated by passing an electric current through a band of iron encircling the wheel; the resulting stresses were calculated from

strain-gage measurements after correcting for thermal expansion.

Twenty-eight wheels of varying weights and design from three manufacturers were tested in this manner, of which sixteen failed by cracking in the plate. Although the total number of wheels tested is too small to draw any definite conclusions, the results seem to point to the following generalities which should be confirmed by a greater number of tests:

1 The maximum stresses developed are very close to the tensile strength of the cast iron and are some function of the strength of the iron.

2 The maximum tensile stresses occur in a radial direction near the junction of the double plates in the M.C.B. or Washburn type of wheel. In the arch-plate type the maximum stress is somewhat nearer the hub. This seems a desirable condition in that it lies in the region where it is counteracted by the strains due to forcing the wheel on to its axle.

3 The stress in a tangential direction on the outer face and also the stress in both the radial and tangential directions on the bracket side of the wheel are relatively small when compared to those in a radial direction on the outer face of the wheel.

4 By proper distribution of metal in the single-plate type of wheel there would appear to be a possibility of securing a wheel more capable of meeting service requirements.

5 With identical rates of heat input the heavier-weight wheels withstand the effect of tread heating with less strain than the lighter wheels.

6 The tests also lead one to believe that the operating conditions to which wheels are subjected may be as important a factor in the safety of the wheel as are the problems arising in their manufacture.

G. K. Burgess and R. W. Woodward conducted these experiments and have described them in Technologic Paper No. 209. Address Superintendent of Documents, Government Printing Office, Washington, D. C. Price 5 cents.

Ropes and Cables A1-22. TEST OF MANILA ROPE. See *Cables and Ropes A1-22.*

Sound A1-22. SOUNDPROOF PARTITIONS. The results of an investigation of the acoustic properties of various building materials with their practical applications by Prof. F. R. Watson have recently been published as Bulletin No. 127 of the University of Illinois, Engineering Experiment Station, Urbana, Ill. The purpose of this investigation was to meet the demand for quiet rooms in hospitals, hotels, and office buildings and the desirability of insulating music studios and other rooms where disturbing sounds are produced; the necessity for solving other problems for the control of noise has led to repeated requests from architects and builders for reliable information on effective methods for insulating sound. Although present knowledge of the subject is incomplete, nevertheless, on account of the pressing need for guidance in such matters, it is thought desirable to collect and present the available information in a systematic way, giving the methods and results of various investigations relating to the action of materials on sound describing practical installations of soundproofing, and setting forth in accordance with existing knowledge recommendations that may be applied where sound insulation is wanted.

Wood Products A1-22. RED HICKORY AS STRONG AS WHITE HICKORY. The insistence of the public on having only white hickory in tool handles and vehicle parts causes a large part of the hickory grown in this country to be used for fuel or for other purposes where the exceptional strength properties of this wood are not needed. Usually only a small outer portion of a mature hickory tree contains white wood; the inner part, or heartwood, is red. Many people think that this red wood is not so strong or tough as the white wood. This belief, however, is discredited by actual strength tests made at the Forest Products Laboratory upon many specimens of red and white hickory. The tests show conclusively that, weight for weight, sound hickory has the same strength, toughness, and resistance to shock, regardless of whether it is red, white, or mixed red and white. Address the Forest Products Laboratory, U. S. Forest Service, Madison, Wisconsin.

Wood Products A2-22. WHEN PRESERVATIVE TREATMENT OF WOOD IS AN ECONOMY. Although any set of timbers may be made more resistant to decay by preservative treatment, such treatment may not always be economical, even though the timbers are to be exposed to the most severe fungus attack. If the timbers are to be in service for a short time only, durability is unimportant, and any kind of preservative treatment would obviously be a waste of money. If, on the other hand, the wood is naturally of low durability and is to be used in a permanent location, it is easy for preservative treatment to show great savings. Between these two extremes there are any number of instances in which it is a more difficult problem to determine whether or not preservative treatment will pay.

If a timber user knows the average life that treated and untreated timbers are giving and the cost of each in place, he can easily compute, with the use of a table recently published by the Forest Products Laboratory, the relative annual cost of maintaining the two.

If untreated timber is giving long life, treatment might not result in great savings. However, very often it might be possible to substitute for such timber a treated lower-grade material that would give as long or longer life with an annual maintenance charge which would compare very favorably with that of the better-grade, untreated timber. Address the Forest Products Laboratory, U. S. Forest Service, Madison, Wisconsin.

B—RESEARCH IN PROGRESS

The purpose of this section of Engineering Research is to bring together those who are working on the same problem for cooperation or conference, to prevent unnecessary duplication of work and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

Corrosion B2-22. CORROSION OF CHROMIUM STEELS. See *Steel, Its Treatment and Products B3-22.*

Foundry Equipment, Materials and Methods B3-22. MOLDING SAND. The Committee on Molding Sand Research, the organization of which was reported in the Engineering Research section of the February issue of MECHANICAL ENGINEERING, is making good progress. A Sub-Committee under the chairmanship of Prof. H. Ries, of Cornell University, is undertaking through the coöperation of the U. S. Geological Survey and the various state geological surveys a comprehensive survey of the molding-sand resources of the country.

The work on the standardization of tests is well under way. Questionnaires have been sent out to gather information on the present methods of testing the physical properties of molding sand and a digest of the replies to these questionnaires is expected to be available shortly.

Many firms and universities have offered to coöperate in the research work. Every endeavor will be made to maintain their interest and to assign problems to those universities and industrial laboratories offering to coöperate; due regard being given to the facilities and talent available. A list of research subjects has been compiled, which is given in part below.

1 Recovery of used molding sand through restoring bond to the sand by subjecting it to contact with water vapor under high pressure
2 The effects of additions of certain chemical reagents upon the physical properties of clays and clayey materials, such as molding sand
3 Effects of water content on the bond and permeability of a molding sand
4 Effects of different water per cents in molding sand and on the milling and drilling speeds of light gray-iron castings
5 Research on fusion quality of facings (Function of "peeler")
6 Tests of various kinds of clays for restoring bond to molding sand
7 Comparison of lives of different molding sands
8 Effects on plasticity of bond in molding sand and reduction of water content when using oil
9 Effects of wet and dry storing of sand on bonding quality.

Fuels, Gas, Tar and Coke B1-22. WATER-GAS TAR EMULSIONS. In Reports of Investigations, No. 2331, William W. Odell, gas engineer of the Bureau of Mines, outlines the essential facts so far brought out in an investigation into the causes for emulsion difficulties as experienced at many water-gas plants. The investigation was conducted under a coöperative agreement between the University of Illinois Engineering Experiment Station, the Illinois State Geological Survey, and the U. S. Bureau of Mines. Funds of the Illinois Gas Association were used to defray a part of the costs.

Active assistance was rendered by the Peoples' Gas Light and Coke Co. of Chicago, who furnished a laboratory at Chicago for conducting the experiments, and loaned the services of E. A. Thiele to help with the laboratory work.

A full report on the results of this work will be published by the Bureau of Mines later, but it is believed desirable to bring the principal results now to the attention of the industry.

This report discusses the subject under the following heads, (*a*) Water-Gas Tar—What it really is, (*b*) Water-Gas Tar Emulsions and Their Formation, (*c*) Quality of Water-Gas Tar, (*d*) Factors Affecting the Settling of and Formation of Tar Emulsions, (*e*) Summary and Conclusions.

Copies of this report may be obtained by addressing H. Foster Bain, Director, Bureau of Mines, Washington, D. C.

Heat Transmission B2-22. HEAT TRANSMISSION THROUGH ENGINEERING MATERIALS. The Annual Report of the Engineering Division of the National Research Council contains a statement concerning the effort which is being made to organize a committee for the purpose of investigating the problems of heat transmission. These problems are important and fundamental to many industries. At the present time, however, there is no exact information on the heat conductivity of many materials. This is due largely to a lack of standardization of apparatus and methods which has resulted in a wide divergence of experimental results. Several societies now have committees organized for investigations of this kind and numerous investigators are at work in the university, industrial and governmental laboratories. The Division of Engineering with the coöperation of the Division of Physical Sciences plans that the new committee will coördinate all the present activities into a comprehensive program. Address Alfred D. Flinn, Chairman of Division of Engineering, National Research Council, 29 West 39th Street, New York.

Magnetism B1-22. MAGNETIC MEASUREMENTS ON SMALL SAMPLES OF MATERIALS. The standard methods of making magnetic measurements which are now in use require relatively large samples of material. While these methods are fairly satisfactory for most purposes, many

cases occur where it would be desirable to make reliable measurements on smaller samples. For example, in researches on the properties of different materials and in the development of materials for particular purposes, the expense would be very greatly reduced if small samples could be made to serve. In order to meet this need, a special study has been made at the Bureau of Standards, and apparatus has been constructed which requires a sample only 10 cm. long and 6 mm. in diameter. This work is not yet complete, but the data already obtained indicate that the apparatus will give very satisfactory results.

Steel, Its Treatment and Products B4-22. Corrosion of Chromium Steels It appears from a series of tests on the corrosion of chromium steel that the behavior of the material when subjected to the acid test is not a sure criterion of its resistance to atmospheric corrosion. Of all the alloys examined, a high nickel-chromium steel, invar, pure iron, and medium-carbon steel (very slowly cooled from a high temperature) were the most resistant to hydrochloric acid as measured by the loss of weight per unit area per day. High-chromium steels (for example, 13.70 per cent Cr, 0.29 per cent C) were found to be attacked by acid very much more readily. However, when the same specimens were subjected to a weathering test, consisting of a partial immersion in water and exposure to the air, the order of resistance was almost completely reversed. The high-chromium steels were the ones to withstand the treatment best, the low-chromium ones and the pure iron showing rust spots early in the test. The combination of both nickel and chromium appears to make the steel resistant to both acid and weather attack. In general, the steels which were quenched were found to resist corrosion better than the same material in the annealed state, but the differences found were much less than the differences resulting from composition changes, thus indicating that composition rather than treatment should receive primary consideration. Address Dr. S. W. Stratton, Department of Commerce, Bureau of Standards, Washington, D. C.

Steel, Its Treatment and Products B3-22. Cutting Tests of High-Speed-Steel Tool Bits. The Bureau of Standards has completed during the past month about 60 more tests on $\frac{1}{2}$-in. tool bits made of several grades of high-speed steel which had been subjected to various heat treatments. A preliminary summary of a portion of these tests for one steel containing 0.62 per cent carbon, 3.5 per cent chromium, 15.5 per cent tungsten, and 1.6 per cent vanadium was made. An interesting feature of these tests is the effect of the temperature of preheating on the cutting qualities of the tools as expressed in pounds of metal cut away. This is shown in the following table:

Preheating (Time for cut. 20 minutes)	Hardening (Time for cut. 5 minutes)	Lb. of metal cut per tool (4 tools tested)
1400 deg. fahr.	2417 deg. fahr.—oil	9.1
1500 deg. fahr.	2417 deg. fahr.—oil	10.1
1600 deg. fahr.	2417 deg. fahr.—oil	5.1
1600 deg. fahr.	2417 deg. fahr.—water	5.1

(All testing conditions were the same)

The results obtained when using water as the quenching medium are about the same as when using oil for this particular purpose.

D—Research Equipment

The purpose of this section of Engineering Research is to give in concise form notes regarding the equipment of laboratories for mutual information and for the purpose of informing the profession of the equipment in various laboratories.

Forest Products D1-22. The Forest Products Laboratory, Madison, Wis. The Decennial Celebration of the founding of the Forest Products Laboratory at Madison, Wisconsin, is the immediate reason for the publication of a handsomely printed booklet, descriptive of the history and work of this well-known laboratory. This book, which is fully illustrated, contains 196 pages and has chapters on the following subjects, (*a*) Wood and Human Progress, (*b*) Early Perspectives of Forest Utilization, (*c*) The Forest Products Laboratory, (*d*) Ten Years of Research in Forest Products, (*e*) Financial Value of Research Results, (*f*) Future Research in Forest Products, (*g*) How to Use the Laboratory.

F—Bibliographies

The purpose of this section of Engineering Research is to inform the profession of bibliographies which have been prepared. In general this work is done at the expense of the Society. Extensive bibliographies require the approval of the Research Committee. All bibliographies are loaned for a period of one month only. Additional copies are available, however, for periods of two weeks to members of the A.S.M.E. These bibliographies are on file at the office of the Society.

Fuels, Gas, Tar and Coke, F1-22. Bibliography of Literature on Sampling. So far as known there is no complete bibliography on sampling so one recently compiled by W. J. Sharwood and M. W. von Bernewitz should be of value. It contains nearly eleven hundred references, some dating back 30 years, on sampling at mines, mills, smelters, power plants, pumping stations and refineries. For convenience, it includes a few references to methods for sampling such materials as leather belting in mills, salt-impregnated soils, and mine waters. All the important technical journals, including some of those published in foreign countries, and mining and metallurgical textbooks, have been studied for anything concerning sampling. The arrangement is alphabetical by authors' names, and the items are numbered serially. A copy of this bibliography can be obtained on application to H. Foster Bain, Director, Bureau of Mines, Washington, D. C. It is known as U. S. Bureau of Mines, Reports of Investigations No. 2336.

Machine Design F1-22. Oil Films in Bearing. A bibliography of $3^{1}/_{2}$ pages. Search 3471.

WORK OF THE A.S.M.E. BOILER CODE COMMITTEE

The Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York, N. Y.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in Mechanical Engineering.

Below are given the interpretations of the Committee in Cases Nos. 391 to 394 inclusive, as formulated at the meeting of April 6, 1922, and approved by the Council. In accordance with the Committee's practice, the names of inquirers have been omitted.

Case No. 391

(In the hands of the Committee)

Case No. 392

Inquiry: If the holes in a plate are drilled full size in the plate before the sheet is rolled and holes in butt straps are also drilled full size before being attached by tack bolts to the plate, would this meet the requirements of Pars. 253 and 254 of the Code?

Reply: The intent of the requirement in Par. 253, that the plates shall be firmly bolted in position for drilling, is to make the holes match perfectly and it is the opinion of the Committee that this can be accomplished only by reaming or drilling the plates after rolling and with the butt straps in position.

Case No. 393

Inquiry: Should the factor "E," in Par. L-43*b* of the Locomotive Boiler Code, be calculated in a longitudinal direction, or transversely, as is "s?"

Reply: "E" refers to the minimum efficiency of the wrapper sheet through joints or stayholes located on a longitudinal section, as explained by the paragraph immediately following the formula.

Case No. 394

Inquiry: Is it permissible to stamp A.S.M.E. Standard on a low-pressure heating boiler which has autogenously welded joints and stays but complies with all requirements of the present Code?

Reply: At the time the heating boiler code was adopted, the use of autogenous welding in the construction of boilers for this service was not contemplated, and no permission for their use is contained in the Code. However, it is the opinion of the Committee that properly designed and constructed welded steel-plate boilers built of material in accordance with the specifications in the heating boiler section of this Code, when constructed, tested and operated in accordance with the rules in that section may safely be used and may be stamped A.S.M.E. Standard, for a working pressure not to exceed 15 lb. per sq. in. steam pressure, or 50 lb. per sq. in. hot-water pressure. The decision whether such boilers may be used thus necessarily rests with the authorities having jurisdiction.

Part I, Section 2 of the Code is now being revised and this interpretation is subject to the rules for welding of heating boilers which will be incorporated therein.

Intermittent Operation of American Industry

THERE are two forms of intermittent operation in American industry: First, that which obtains every seven to ten years and is commonly referred to as the Business Cycle or Cyclical Depression; second, that form usually referred to as Intermittent Employment or Seasonal Operation.

L. W. Wallace

The wonder is that these forms of business depressions have not been given the consideration and constructive thought that their magnitude and their seriousness demand.

The ill effects of the cyclical depression are immeasurable. It is known in a general way that through the workings of the business cycle millions of men and women are forced out of employment for months at a time, yet at no time or place has there been accumulated authoritative information as to the primary causes of such depressions. There is no source that one can turn to for helpful suggestions as to what measures may be invoked to forestall the evil day or to mitigate its destructive influences once it has arrived.

Federal and state legislative bodies, fond though they appear to be of passing legislation pertaining to business, have not evolved any constructive legislation bearing upon this serious economic and social phenomenon.

Senator Kenyon, in the last days of his service in the U. S. Senate, did introduce a bill which contained a fundamental conception of the problem and which did at least suggest a means of preparing for cyclical depression. The preamble to this bill stated:

> Whereas a sound economic policy requires that a larger percentage of the public works and projects of the United States be undertaken and prosecuted during a period of major industrial depression and unemployment, when labor and capital are not fully employed in private industry, that a smaller percentage of such works and projects should be undertaken and prosecuted during a period when industry is active and competing for the same men and material with resulting business strain and overextension, and that the prosecution of such works and projects should be utilized as a stabilizing force during a period of overexpansion as well as during a period of depression, it is the purpose of this Act to grant the authority necessary to carry out this policy.

This bill met with such opposition that Senator Kenyon moved that it be referred back to the committee. This was done and thus one earnest effort to undertake some solution of the problem was disposed of. Future efforts, it is hoped, will be more successful.

The Permanent Committee of the President's Conference on Unemployment has recognized the problem as one of great importance and seriousness. It has therefore secured sufficient funds to finance a comprehensive study of the business cycle. This study is now being conducted by Dr. Wesley Mitchell and associates, assisted by a number of organizations.

The Federated American Engineering Societies is conducting one phase of the study. It is being assisted by over one hundred and twenty different groups of engineers. This is the first comprehensive study of business cycles ever undertaken. The results to be disclosed, when the work is completed, promise to be of very great importance. It is expected that from this study there will come such concerted action as to greatly reduce the ill effects of cyclical depressions in the future.

It is the belief of some, which belief is based upon a large amount of data, that the economic, civic and social losses due to seasonal operation are even greater than those due to business depression such as is now being experienced. This phase of American industry has not challenged the thought of those concerned as its seriousness demands. For instance, but few have known or realized that—

(1) In 1919, the employees in the paper box, women's clothing, confectionery, overalls, brick, chemical and glass industries lost from 10 to 15 per cent of the possible working days

(2) Bituminous coal mines have operated on an average of only 214 days per year since 1890, the loss in time being an average of 90 days per year

(3) The annual loss in the shoe industry due to seasonal operation is approximately $65,000,000

(4) In the clothing industry there is an extensive unemployment period twice a year which averages 31 per cent of the possible working days and affects from 80 to 90 per cent of the workers

(5) The worker in the construction industry works on the average of only 190 days in the year, that is, he is idle 33 per cent of the time. Many other examples might be cited.

It is a safe assumption that in most of the industries the plant equipment and the materials in stock are idle the same percentage of the time that labor is. All of this contributes a large amount of the unearned overhead account.

In this connection it is of importance to note that it is in the most highly seasonal industries where bitter and costly labor difficulties occur the most frequently. In 1919 in New York state 32 per cent of all the strikes were in the construction and clothing industries, the two that operate largely upon a seasonal basis.

It is recognized that it is a difficult task for some industries to avoid seasonal aspects. But it is also known that some industries that were once considered unalterably seasonal in character now operate on a uniform schedule throughout the year. These industries carefully analyzed the problem, thereby disclosing the changes necessary to be made in practices and policies in order to eliminate the evil. When these necessary changes were adopted, a greatly improved condition obtained.

This aspect of American industry requires careful study upon the part of some authoritative, competent and unbiased group. It would be of great assistance for all concerned to have full information as to what each individual plan has done to reduce the seasonal aspect of its operation. This information would stimulate others to make a similar effort.

The elimination of the losses due to cyclical depressions and to seasonal operation of American industry will require earnest, continued and persistent effort. They are not common to one plant or industry, hence the manager of no one plant or industry can adequately deal with them. They can be adequately dealt with only through collective action.

The best means of accomplishing the necessary collective action is through the coöperation of trade associations and engineering societies. These problems should challenge the efforts of such organizations, because in their solution lies a very large economic and social advancement of the body politic. L. W. Wallace.[1]

[1] Executive Secretary to the American Engineering Council.

The Growing Importance of Safety Codes

THE engineering profession has always been one of the leaders in the development of anything of service to the human race, ready to further every sensible means or method which has for its object the safeguarding of the worker against the hazards of his occupation or the safeguarding of the public against the risks that it must take in connection with the use of public or private conveyances.

John W. Upp

The engineer cannot condone the lack of safeguards which, if used, would eliminate unnecessary risks and reduce the number of injuries. For the workman will do more and better work if he is relieved of the nervous strain which he must continually undergo when he knows that, as in the case of unguarded machines, the slightest slip or inattention may result in temporary or permanent injury.

The number of preventable accidents which are constantly taking place is of real concern to the designing engineer and is an incentive for him to improve the operating efficiency of the inanimate machine as well as to secure the efficiency of human endeavor by reducing to its lowest point the harmful results that come from the operation of such a machine improperly safeguarded. He desires to increase efficiency in operation, but the loss of hands, legs, eyes or earning capacity is to him more objectionable than loss in horsepower.

The engineer has often acted individually to introduce safeguards which could be successfully financed through the coördination of the adverse interests involved. But progress has been slow because the individual as well as the corporation has a well-understood tendency to follow the old and accustomed standards unless some concerted action is taken to get them out of the beaten path. Because of established practice it often takes a long time before satisfactory results can be accomplished.

We have reached the point, however, where the efforts of the engineer to introduce his own ideas and measures for safety in the individual installation can now be combined with the efforts of practically the entire fraternity working along similar lines. We can codify for general use the knowledge of the group, and with the backing of a Society such as ours and the help of other interested bodies of national standing, we can disseminate that knowledge for the guidance of all concerned in the operation of the machinery coming under the classification of a given code.

The code brings together for easy reference and use the combined practical experience of the recognized leaders in the profession. It greatly assists in the application of safety devices because it lists only the rules and regulations which have been put to the test and proved of value.

An adopted code is a definite help in the process of standardization because when the code is accepted the devices which meet the specifications are uniformly manufactured. This means that the design will be in the hands of the manufacturer—where it belongs, but the inefficient and troublesome practice of making changes in details of construction to satisfy the varied personal ideas of the many individuals authorized to give approvals in the different sections of the country will be eliminated.

A code decreases the cost of manufacture and the price to the user because of the reduction in the number of special devices, and it will improve the quality and the performance of the devices themselves. For when the manufacturer feels that his equipment will be passed as satisfactory if it meets the degree of safety called for in a uniform set of regulations, he will naturally spend more time and money in the development of devices or machines which he can sell in comparatively large quantities. More attention can be paid to economical design, important tool equipment can be introduced, and a more satisfactory article produced and at a lower cost.

The safety code grows in importance as its purpose and benefits become better understood, for from whatever angle the subject is approached, the conclusion must be reached that the code, properly prepared, is the best means so far developed for assisting in the application of safety devices and the reduction in the accident hazard.

We should not leave this subject without paying respect to the excellent work that engineers connected with the Society have done in the development of safeguards for use on moving machinery, but we may be pardoned for suggesting that there is much more to be done in this direction. We hope that every member of the Society will consider himself responsible in some measure for carrying on this useful work, and when a code has been sanctioned by the Society that each member will familiarize himself with its contents and give the weight of his good will to the rules and regulations on every suitable occasion.

John W. Upp.[1]

Engineers Again Needed in Patent Legislation Situation

DURING the month of March there were introduced into the Senate two bills seeking to amend the patent laws, which, in the opinion of the writer, are exceedingly dangerous and which, if passed, would be destructive of the American patent system. These are Stanley Bill, S-3325, providing for the granting of compulsory licenses where patents have not been worked to a reasonable extent within a reasonable time, which amended Section 4887 of the Revised Statutes of the United States; which bill was replaced by Stanley Bill, S-3410, which applied the same amendment to Section 4886 of the Revised Statutes. The former Stanley Bill might, in effect, apply only to foreign-owned American patents, but the substitute bill would unquestionably apply to all United States patents, whether owned by American citizens or aliens. The questions of whether a patent had been worked to a reasonable extent and within a reasonable time, are to be decided by the Commissioner of Patents or such other governmental agency as the President shall designate. The Ladd Bill, S-3297, was also introduced, and this bill provides that patents shall lapse if not worked within five years after they are granted, or two years after they have been assigned. These bills would so lessen the value of patents that the incentive to produce inventions would be so greatly decreased as to put our American patent system in the position of a second- or third-class system and deprive our country of that incentive to invent which has made us the foremost country in inventiveness, in manufacturing, and in agriculture.

The object of the bills is to throw German-owned American patents open to American use and prevent the Germans from manufacturing in Germany and importing here, while restraining the use of their invention here through their American patents.

The International Convention, to which most of the leading countries are parties, would prevent a working clause in our law which applied only to aliens. Therefore, the Stanley and Ladd Bills apply to all American patents.

The path which an inventor must travel before he can reap any return is already so difficult that many doubt that it is worth while to make inventions. The cost of "working" a patent is sufficiently large, so that if it had to be done merely to keep the patent alive, and whether commercial conditions would justify it or not, it could not ordinarily be undertaken, and most patents would lapse for that reason.

Few individuals or corporations would buy patents with a working clause hanging over them. Those patents which only become valuable and profitable during the last two or three years of their life would almost always have lapsed before that period would have been reached, to the embitterment of their inventors or owners and to the discouragement of all who knew of the experience. Where, as is usually the case, a development requires a number of years and the production of a series of patents, either for successive improvements or for auxiliary inventions, the expense of working a number of patents would be incurred, and the earlier patents would often have to be worked before the development had reached a successful conclusion and hence without any knowledge that any working would ever be justified.

---

[1] Manager, Switchboard Dept., Gen. Elec. Co., Schenectady, N. Y., and Chairman of the Standing Committee on Safety Codes.

Where it was necessary to patent several alternative inventions and no basic patent could be obtained to cover all the forms, each of the alternative forms would have to be worked to keep out competition. The expense of this possible multiple working would deter many manufacturers from entering at all upon a development. The working or compulsory license requirements would favor the rich inventor or corporation as against the poor inventor.

For these reasons, the market for patents would be largely decreased and hence the incentive to invent severely lessened to the defeat of the object of the patent system.

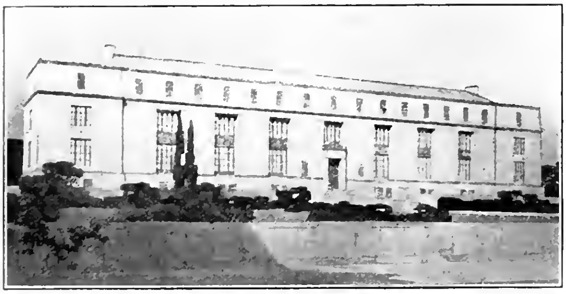
The Patents Committee of the American Engineering Council has been authorized to vigorously oppose the passage of the bills.

The Patents Committee of the Senate held a hearing on the Stanley Bill, S-3410, on April 6 and, because of protests at the shortness of the notice, the hearing was continued to May first and second. The Patents Committee of the Council arranged for a delegation to appear at the hearing, and a vigorous argument and protest against the passage of the bills were made.

Edwin J. Prindle, *Chairman*,
Patents Committee, American Engineering Council.

National Academy of Sciences and National Research Council to Have New Building

Plans for the erection in Washington of a $1,300,000 building as the home of the National Academy of Sciences and the National Research Council and a center for American science in all its fields have been announced by Dr. C. L. Walcott, President of the National Academy. The building, the completion of which is expected by a year from next fall, is the gift of the Carnegie Foundation of New York.



Artist's Drawing of the New Building for the National Academy of Sciences and the National Research Council

In addition to serving as a conference center for scientists, the institution will be designed as a "mutating museum" of the progress of scientific achievement. A large auditorium and a lecture room on the main floor will be surrounded by seven exhibition rooms, in which the newest scientific discoveries will be illustrated for the benefit of the public. One of the most interesting features of the building will be a coelostat telescope which will throw a large image of the sun on a white surface and demonstrate to the layman the natural phenomenon of sun spots.

Second Public Conference on Commercial Engineering

Engineers, business men, and educators from all parts of the country met at the public conference on Commercial Engineering held May 1 and 2 at Carnegie Institute of Technology, Pittsburgh. It was the second public forum on this subject, and was called by the U. S. Commissioner of Education on behalf of a national committee appointed to investigate business training of the engineering student, and engineering training of the business student.

The term "commercial engineering" is rather new; but the need for it is an old one. The primary cause of the investigations and the subsequent conferences was the realization among industrial executives that engineers were overtrained technically, and undertrained commercially. The necessity of a business training along with engineering development is felt by every engineering student soon after leaving college. To bring about a better coördination of college curricula as the means to make better business men of engineers, and conversely, better technically trained business students, was the basis of the conference discussions.

The convention provided the rare opportunity for industrial executives to tell educators where engineering students fell short as soon as they entered industrial life. Educator met educator and exchanged ideas on the best methods to coördinate business and engineering courses.

The first three sessions of the conference were group sessions where the following topics were discussed: Current practices in colleges and universities relating to business training for engineers and engineering training for business men; coördination of college training with the industrial demand; and civic and social training of the engineer and business man. The fourth session of the conference was a series of group conferences where the topics of the first three sessions were again the subjects of discussion and where the fourth group met to talk over the training of the engineer for management of overseas engineering projects.

Internationally known engineers, business men, and college executives spoke at the various sessions, and many prominent men took active part in discussing the various angles of the problem. Samuel Insull, President of the Commonwealth Edison Co., F. B. Jewett, Vice-President of the Western Electric Co., Eugene Meyer, Jr., Director of the War Finance Corporation, Dr. C. R. Mann, of the War Department, Dean Dexter S. Kimball, President of The American Society of Mechanical Engineers, and L. W. Wallace, Executive Secretary of the Federated American Engineering Societies were prominent speakers or group chairmen.

A Discussion of Draft-Tube Designs

To the Editor:

Referring to Mr. W. K. Ramsey's paper entitled A Discussion of Draft-Tube Designs, published on pages 171–176 of the March issue of Mechanical Engineering, I beg to take exception to the author's views upon the cause of the phenomenon of water being drawn up in the central region of a draft tube at lower gates.

Mr. Ramsey ascribes this phenomenon to the action of a "great centrifugal force of water whirling down a draft tube." According to his description "this column ascends to a point directly beneath the runner where it turns over and down and is discharged down the tube." Further down on the same page (171) we read that "when the runner is discharging water at best gate, the water is flowing down in practically straight stream lines" and "under this condition there is no centrifugal action to cause the water to be drawn up from the tail race."

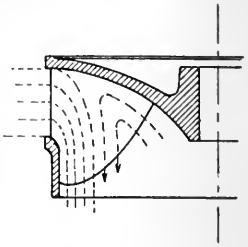


Fig. 1

I wish to remark that the phenomenon in question has been known for a long time and was long ago explained. Being due to the action of runner vanes, the inner parts of which run empty at lower gates, it has been named "pumping action." The ascending column of water goes further up than the point "directly beneath the runner;" it enters the runner, fills its empty space, and is discharged from it (see Fig. 1). This pumping action goes on at the expense of energy of a runner and is largely responsible for the decrease of efficiency of turbines at lower gates. It is to some extent controllable by suitable runner design. Of course there can be no pumping action in turbines at full gate, no matter what may be the direction of the velocity of discharge.

Those interested may find a full explanation of the matter in the works of R. Honold (Honold-Albrecht, Francis Turbinen, Mittweida 1907, pp. 56–57) and Professor Camerer (Vorlesungen über Wasserkraftmaschinen, Leipzig, Engelmann, 1914, p. 360).

Engineering and Industrial Standardization

Machine-Tool Elements to be Standardized

As the result of a joint conference which was held in Atlantic City on April 26 it is more than probable that the standardization of certain machine-tool elements will be accomplished in the very near future. This joint conference between representatives of the National Machine Tool Builders' Association and The American Society of Mechanical Engineers was part of the regular program of the Association's Spring Meeting.

These two organizations, having sometime ago accepted joint sponsorship for a Sectional Committee which is to undertake this work under the Rules of the American Engineering Standards Committee, arranged for this conference to determine which of the machine-tool elements should be considered first. General Manager E. F. DuBrul who presided at the conference reported the results of an investigation which he has been making into the size, proportions and spacing of tee (T) slots as found on the various machines now on the market. This report opened up the subject completely and many of those present took part in the discussion. A few of the machine-tool parts and dimensions which in the opinion of the conference should receive the attention of the Sectional Committee are listed below under the heads of the machine tools to which they apply:

LATHE

1 Tee (T) slots
2 Standard rating (What is a 14 in. lathe?)
3 Nose piece
4 Bolt heads and nuts

DRILLS

1 Tee (T) slots
2 Spindle nose
3 Taper

MILLING MACHINES

1 Tee (T) slots
2 Spindle ends
3 Angle blocks
4 Bolt heads and nuts

PLANER

1 Tee (T) slots
2 Bolt heads and nuts
3 Distance between housing
4 Length of bed

BORING MILLS

1 Tee (T) slots
2 Ram and turret tool holders
3 Diameter of hole in table
4 Bolt heads and nuts

It will be seen that the majority of these elements can be classed as tool or work-holding elements. This brings us to mention the key-note of the conference, namely, "the purchaser should have something to say." The Sectional Committee which is being organized to carry on this work will consist of representatives of the manufacturers (producers), users (consumers), and general interests (neither one nor the other). All those who are or have been in touch with a machine shop in which are installed various kinds of machine tools and various makers of the same tool need not be told of the great saving in cost of parts of jigs and fittings and in time due to interchangeability, which would result from the standardization of certain of the elements common to a number of machines.

At the close of the discussion it was agreed that a Plan and Scope Committee be first organized to make a careful survey of the field which is to be covered by the work of the Sectional Committee and to assist in determining its personnel. It was suggested that this Committee consist of five representatives of the N.M.T.B.A. and five representatives of the A.S.M.E. and it was further decided that the representatives of the N.M.T.B.A. should be drawn one each from the manufacturers of the following five types of machine tools:

(1) Planing
(2) Work revolving
(3) Tool revolving
(4) Grinding
(5) Punching and forming.

The dealers also are to be asked to coöperate by making suggestions for the use of the Committee and by assisting in the promulgation of the standards when they are developed.

Standardization—Its Fundamental Importance to Prosperity

This is the subject which Mr. Charles le Maistre, Secretary of the British Engineering Standards Association, chose for his address before the General Meeting of the North-East Coast Institution of Engineers and Shipbuilders held at Newcastle-upon-Tyne the last week of March. While speaking of the general principles underlying standardization, he said in part:

> Standardization is not an easy term to define. There is nothing, however, new in the idea, for it has been practiced in one form or another for many centuries, and starting from the moral and social side with standards of conduct, standards in art and in literature and so forth, has in later years gradually developed as an economic movement in the production of the material necessities of life, a departure of interest to everyone, seeing that it implies both the study and the preparation, as well as the recognition of standard forms and qualities. In its broadest aspect it may be said to imply the introduction, through collective effort, of economical methods of manufacture, not so much with the idea of gaining dividends as of unifying the needs of industry and thus bringing about the greatest amount of good for the greatest number. But it is not so much a definition of standardization that is wanted as an understanding of its underlying principles, and perhaps the best way of arriving at this is through actual experience in the working out in practice of the standards.
>
> It is still sometimes urged against standardization that it retards invention and progress, and that once a standard has been adopted there is no possibility of modification or change even though new methods may have demonstrated their superiority over the old. Happily this is not the case so far as industrial standardization is concerned when carried on along right lines. Of course, crystallization which would tend to impede or hamper progress must be jealously guarded against so that the work may be of permanent value and the purchaser reap the benefit of competitive effort and inventive genius. Periodic review prevents crystallization and keeps the work abreast of progress. Nor is standardization coercion either by Government or by one section of the community over the other: indeed, there is nothing compulsory in it at all, its only authority being industrial public opinion.
>
> Industrial standardization does not necessarily involve the idea of actual perfection; it is rather the registering of what is best in present practice as against attempting to set up an ideal. It is quite easy to set up a standard, but it is altogether another thing to get that standard widely adopted, and a standard which is not in accordance with the fundamental needs of industry, that is, which does not fulfill a recognized want, is economically a bad one. It is a wasted effort and a pitfall for the unwary.
>
> In carrying out the work of industrial standardization, the aim should be to unify the requirements of industry to the best possible advantage without striving for an ideal which might involve an unnecessary sacrifice of capital. It is the buyer in the first instance to whom standardization is of the utmost value, for it enables him to know exactly what he can purchase and to be sure that he gets what he asks for in return for his money. But it is of equal value to the manufacturer for it simplifies his work, it enables him to produce what is required by the purchaser cheaply and expeditiously, as well as to avoid mistakes. It will thus be seen that the community of interest of the buyer and seller is one of the fundamental ideas underlying the work, for there cannot be the least doubt that the interests of both are really identical.
>
> Every problem of standardization may be divided into the technical and the human side, and in most cases the human side is well over 85 per cent of the total. The technical factors are usually so well known that the problem so far as this is concerned becomes one of basic facts rather than of opinion, but when we come to deal with the human side so very little is known of the reasons actuating us all that we deal largely with so-called human opinion, which sometimes is not too closely related to the facts.
>
> It must be remembered that standardization is really a science all of its own, and it is only gradually that its underlying principles have unfolded themselves and its great economic utility become recognized. Gradually, however, it has come to be seen and appreciated that standardization to be of lasting benefit must first of all be approached through the industrial side, the initial proposals coming from the manufacturers, the constructive criticism being supplied by the scientific and technical experts. That does not say that there are not isolated cases where the reverse is true, and rightly so.
>
> The full realization of the economical side will always result in producing standard specifications which, though perhaps not ideal, yet represent the best which can be devised at the moment, improvements being effected through the process of time.
>
> To be received with confidence by industry, standards must have a certain measure of permanency, and while crystallization must be avoided by periodical review as already mentioned, they must not be changed too often unless the changes are distinctly in the direction of improvements, and safeguards must be created so as to protect those standards from change merely for the sake of change. Standardization, based on these principles, can never result in fossilization or stultification of invention and progress. Indeed, they invite improvement and progress.
>
> Industrial standardization, then, has for its main objects the elimination

of waste of time and material involved in the production of a multiplicity of sizes and qualities for one and the same purpose, the fixing of the dimensions of component parts where interchangeability is necessary, the setting up of standards of performance whereby comparisons can be made with equity as well as the defining of attainable quality of material which involves unification of tests. Rapid and economical production may certainly be claimed as one of the leading benefits, and the securing of this is not only advantageous to the manufacturer but also to the consumer in the rapidity with which his orders can be filled from stock, the ready replacement of damaged and worn parts, and not infrequently the reduction in selling price. Notable examples of the increased business resulting from standardization can be seen in the well-known cases of the ordinary sewing machine and the bicycle. Interchangeability of component parts secured through standardization will give the purchaser the great advantage of an open market.

It should not be forgotten that the setting up of standards or the drafting of national purchasing specifications does not prevent a purchaser from obtaining anything which is not included in those specifications. He may possibly have to pay more for it and perhaps it is sometimes wise that he should. To be of the greatest benefit industrial standardization must be arrived at through the elimination of the unnecessary and the recognition that the recommendations are not unalterable, but rather subject to review, certainly not too frequently as I have already said, but whenever industry finds it economically desirable or necessary to do so.

The aim of those engaged in standardization must be to unify the needs and requirements of industry and that without hampering invention and design, and so encourage and direct progress along the best and most efficient lines.

Standardization, or unification as it might more appropriately be called, as signifying this great community of interest, goes so deep down and touches so closely on life's fundamentals, that to carry it out successfully requires much patience, caution, and evidences of vision, combined with optimism, good will and idealism. Fortunately these qualities are to be found increasingly among those who go to make up the great engineering industry of our country. All who are engaged in serving the public have a unity of purpose which is increasingly recognized, and as time moves on people are more and more willing to sink their individual differences with a view of benefiting the many.

When one considers the public-spirited manner in which so many freely give their valuable time and experience to this work, often at so much personal expense and inconvenience, one realizes indeed what a debt the nation owes to our engineers and business men for the part they are taking in this national work.

Florence M. Griswold Dies

Florence M. Griswold, who was often spoken of as the "Dean of Fire Insurance Engineers," and who was responsible for the standardization of fire-hose couplings, died on April 25, 1922. Mr. Griswold was born in Hoboken, New Jersey, in November, 1843, and received his education in the public schools there and at Wittenburg College, Springfield, Ohio. He served in the Union forces during the Civil War.

At the close of the war he entered the insurance business under the supervision of his father, Jeremiah Griswold, who was the author of many publications on various phases of the insurance business. Until 1875 he was connected with several of the principal fire-insurance companies in various responsible capacities, when he became general inspector of the Home Insurance Co. of New York. Since that time he had particular charge of the special hazards and technical work conducted by this company throughout the whole field of its operation.

When Mr. Griswold entered the insurance business the system was admitted to be one of guessing as to hazards and rates. He began to study the situation in an attempt to reach the scientific principles underlying it. He made himself familiar with the methods of all classes of manufacturing industries and the fire hazards incident to each. He assisted in the organization of many of the inspection bureaus and had an active hand in the formulation of a number of schedules for rating industrial plants.

His investigations naturally led him into the field of fire extinguishment. For many years he worked strenuously to secure universal standards for all classes of fire-fighting facilities and utilities. The National Fire Protection Association selected him to head a special committee to secure the adoption of a universal standard for hose and hydrant threads. Persistent efforts in this direction had failed many times in the past. Mr. Griswold was finally able to secure for his coupling the endorsement of many of the leading and most influential organizations of this country, and its use became general in all parts of the country. In 1917 it was approved and adopted by the United States Bureau of Standards as the "National Standard Hose Coupling and Hydrant Fitting" to be used for public fire service.

Mr. Griswold became a member of The American Society of Mechanical Engineers in 1914. He was also a member of the Grand Army of the Republic, the American and New England Water Works Associations, an associate member of the International Association of Fire Engineers, and an honorary life member of the National Fire Protection Association.

Louis E. Strothman, A.S.M.E. Vice-President, Dies in Milwaukee

Louis E. Strothman

Louis E. Strothman, Vice-President of the Society, died at his home in Milwaukee, Wisconsin, on May 8, 1922, after an illness of some months. Mr. Strothman was born in Milwaukee in 1879 and received his education in the public schools there and at St. John's Military Academy. From 1899 to 1902 he served as draftsman for several Milwaukee concerns, and then entered the employ of the Allis-Chalmers Manufacturing Co., with which he was associated in various capacities until August, 1919. At that time he became vice-president and general manager of the Richardson-Phenix Co., which position he held until his death.

Mr. Strothman had an extensive and varied engineering experience. He was a member of a number of engineering societies, including the American Society of Civil Engineers, the American Waterworks Association, the National Association of Stationary Engineers, and the Engineers Society of Milwaukee, of which latter he was president in 1916–17. In 1916 he was appointed a member of the board of directors of the Organization for National Preparedness for the state of Wisconsin, and was also appointed an associate member of the Naval Consulting Board.

He became a member of The American Society of Mechanical Engineers in 1909 and has taken an active interest in its affairs. In 1915–16 he was chairman of the Milwaukee Section. He served as chairman of the 1917 Nominating Committee and has since that time been a member of the Main Committee on Power Test Codes and chairman of the individual committee on Reciprocating Displacement Pumps. In 1919 he was appointed by President Cooley to represent the Society in company with himself on the National Industrial Conference Board. Later in the same year he was elected manager of the Society to fill a vacancy for a year. In 1921 he was elected Vice-President of the Society, which office he was holding at the time of his death.

The Council of the Society, at the Spring Meeting at Atlanta, Ga., received the news of Mr. Strothman's death with great regret, and voted to appoint a special committee to draw up resolutions to be entered upon the records of the Society and to be sent to his family.

From a close friend of Mr. Strothman's, Henry A. Allen, consulting engineer, Chicago, we have received the following appreciation: "Louis E. Strothman was a gentleman and an excellent engineer, always striving to increase his knowledge and to better the engineering profession. When manager of the pumping-engine department of the Allis-Chalmers Co. about twenty years ago, I had the opportunity of advancing him from the drawing board to the desk, where he handled the estimates and correspondence dealing with centrifugal pumps. He was very efficient and his rise from that time on to manager of the department was deserved and steady. His death was a distinct loss to the engineering profession, and to me and many others means the loss of another long-time dear friend."

Atlanta Papers Elicit Valuable Discussions

Contributions on Fuels, Power and Textile Machinery Prove to be Especially Noteworthy. Dr. Stumpf is Present. Atlanta Section Provides Enjoyable Entertainment Program

WITH a happily balanced technical and social program, preceded by an interesting trip to the University of Virginia at Charlottesville and followed by instructive trips to Greenville, S. C., Birmingham, Ala., and Muscle Shoals, the 1922 Spring Meeting of the American Society of Mechanical Engineers will go on record as the most interesting so far in the Society's history.

The meeting was essentially Southern and the Atlanta Section had carefully planned the entertainment program with hospitality achieved only by the open-hearted. Every detail for the comfort of the guests was amply safeguarded and the 350 who registered enjoyed every moment of their sojourn in Atlanta.

The social and entertainment features were described at length in the A.S.M.E. News for May 22, and a more complete account of the discussions presented at the Atlanta Technical Sessions will appear in later issues of MECHANICAL ENGINEERING.

On Tuesday, the first day of the professional sessions at the meeting, there were four simultaneous attractions. Three of the power test codes were presented for public hearing, and a small group of engineers entered earnestly into the discussion, although no fundamental changes were suggested. The codes presented were, Definitions and Values, Displacement Compressors and Blowers, Hydraulic Power Plants and their Equipment.

There was a large attendance at the first general session, which was presided over by Earl F. Scott, of Atlanta. The paper by Alfred Cotton of St. Louis, Mo., on the Accuracy of Boiler Tests attracted considerable attention and elicited a great many criticisms and comments on the subject matter of the paper. E. R. Fish of St. Louis made the presentation. The feature of the session, however, was the paper entitled Using Exhaust Energy In Reciprocating Engines which had been prepared by Dr. J. Stumpf of Charlottenberg, Germany and C. C. Trump of Syracuse, New York. Mr. Trump presented the paper and was followed in the discussion by Dr. Stumpf, who arrived from Germany in time to reach Atlanta for the meeting. This paper also drew out interesting discussion.

At the session on Materials Handling, which was presided over by R. M. Gates, chairman of the Materials Handling Division, F. L. Estep, Chief Engineer of the firm of Perin and Marshall of New York, presented a paper prepared by F. L. Leach, on the subject of Handling Equipment as Used in the Iron and Steel Industry. Mr. Leach is at present in India engaged in work for Perin and Marshall. This paper recorded the most important handling methods used in the iron and steel industry and brought out discussion as to the economies that may be obtained by the use of machinery in materials handling.

In the absence of Charles T. Plunkett, H. M. Latham, of Worcester, Mass. presided at the first session on Textile Machinery. The papers were those on Cotton-Ginning Machinery by S. E. Gillespie of Dallas, Texas and on the Maintenance Textile Machinery by E. H. Marble of Worcester, Mass.

On Tuesday afternoon a number of members and guests visited the plant of the Atlantic Steel Company, which is entirely equipped for the burning of pulverized coal.

On Wednesday there were three simultaneous sessions. A goodly crowd enjoyed the papers presented at the Fuels Session, which was presided over by F. R. Low of New York. The paper by F. G. Cutler of Birmingham, Ala., on the Reduction of Fuels Waste in the Steel Industry proved to be of great interest. E. A. Uehling of Milwaukee, Wis. was not present to give his paper on the Control of Boiler Operation, but the large number of discussions that were entered proved conclusively that the subject was one of great interest. Boiler Room Performance and Practice at Colfax Station of the Duquesne Light Company by C. W. E. Clarke, of New York, N. Y. brought forth a good round of comment from men engaged in boiler-plant operation.

The second session on Textile Machinery was presided over by H. M. Latham who because of the death of L. B. Jenckes of Worcester, Mass., also presented the paper on Weaving Machinery. The other papers at the session were Extraction of Oil from Vegetable Matter, by Joseph Davidson of Atlanta and Modern Shop Practice in the Building of Revolving Flat Cards, by F. E. Banfield, Jr. of Newton Upper Falls, Mass. All the papers were earnestly discussed by the crowd of textile engineers present.

The Management Session on Thursday, presided over by L. P. Alford was devoted to the discussion of two papers; Management Applied to Textile Plants by George S. Harris of Atlanta and The Southern Worker, His History and Character, by Frank H. Neely, also of Atlanta.

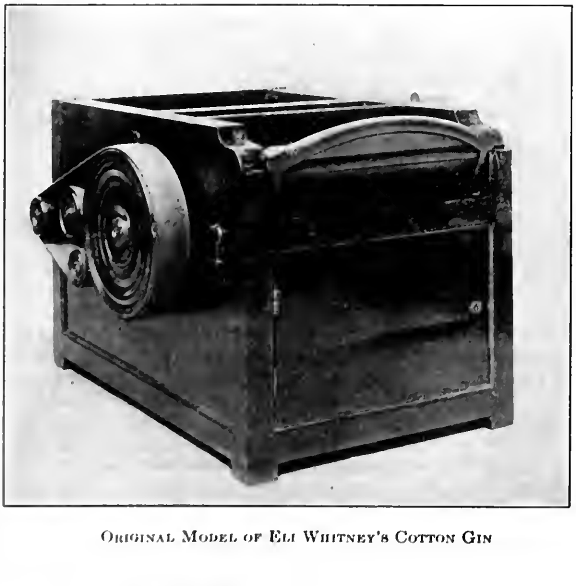
D. W. Mead of Madison, Wis. acted as chairman at the Power Session, which treated some phases of the development of hydroelectric power. Three papers on this subject were presented as follows: Power Development in the Southeast, by Chas. G. Adsit of Atlanta, Economics of Water-Power Development, by C. A. Mees, of Charlotte, N. C., Hydroelectric Power-Plant Design, by John A. Sirnit of Birmingham, Ala. The paper by Messrs. H. B. Reynolds and W. F. Hovey both of New York, which reported the Tests of a 60,000-KW., Cross-Compound, Triple-Cylinder Steam Turbine, was presented by title.

A host of engineers vitally interested in the problems of welding pressure vessels attended the session at which four papers on this subject were presented. Mr. E. R. Fish of St. Louis, presided over the presentation and discussion of these papers. The papers are as follows: Strength of Electrically Welded Pressure Containers, by R. J. Roark of Madison, Wis., Some Principles of the Construction of Unfired Pressure Vessels, by S. W. Miller of Rochester, N. Y., Steel for Forge Welding, by F. N. Speller of Pittsburg, Pa., Tests on Welded Cylinders, by E. A. Fessenden and E. J. Bradford, both of State College, Pa.

Whitney's First Model of His Cotton Gin

A unique feature of the A.S.M.E. Spring Meeting at Atlanta was the exhibition of Eli Whitney's first model of his cotton gin. This model is owned by his grandson, the present Mr. Eli Whitney of New Haven, Conn., who very generously loaned it for the benefit of those attending the Meeting.

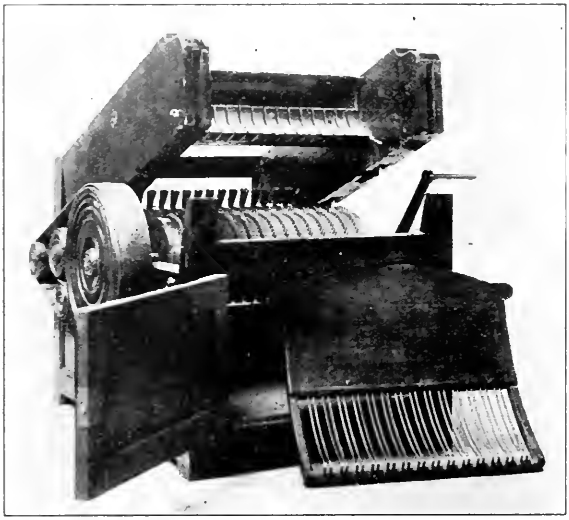
Eli Whitney was born in Westboro, Mass., in 1765 and was graduated from Yale College in 1792. In the fall of that year he was en-



ORIGINAL MODEL OF ELI WHITNEY'S COTTON GIN

gaged as a private tutor in a family in Georgia. On his way there he met Mrs. Greene, the widow of Gen. Nathaniel Greene, who was returning to Savannah from a visit north. On reaching Georgia he found that, despite his engagement, another had been given his place and he was stranded, practically penniless. Mrs. Greene invited the young man to her home until he could find something to do.

Shortly after Whitney's coming, a party of gentlemen from Augusta in the upper country, who had been officers in the Revolution under Gen. Greene, were visiting there. The conversation turned to the depressed state of agriculture in the South. Long-staple cotton had been introduced successfully in the sea islands, but could not be grown inland. Short-staple cotton would grow inland, but was unprofitable as there was no practical means of separating the cotton from the seed. The separation by hand of one pound of staple was a day's work for one woman. During the conversation Mrs. Greene told those present that Mr. Whitney could invent a machine for them that would do the work. This incident turned Whitney's attention to the subject. He went to Savannah, obtained a small parcel of raw cotton and set himself to work on the problem. With the resources the plantation afforded and such tools as he could contrive, he developed the invention in a few weeks and produced his first model, which is exhibited here. This model contains the three essential elements of all cotton gins: namely, the revolving cylinder with forward-pointing teeth; the comb through which the teeth pull the cotton; and the revolving brush to clear the cotton from the teeth.



Same Model Partly Disassembled to Show Mechanism

The cotton gin is justly rated as one of the major inventions in history. No other great invention is so clearly and unmistakably attributable to the work of one man. The modern cotton industry may be said to date from this invention.

For Wartime Government Work, F.A.E.S. Committee Recommends Cost-Plus Contract with Adjusted Compensation

During April the F.A.E.S. Committee on Types of Government Contracts submitted a report after giving careful consideration to a large number of suggestions invited from contractors and other interested individuals.

An abstract of the report is given below. The committee is made up of A. P. Davis, Chairman, Colonel Sherrill, D. Knickerbocker Boyd, Charles E. Ruffner, N. M. McFarland and P. Junkersfeld.

After due discussion the Committee reached the conclusion that all Government contracts should, in the interest of the Government, aim at certain definite objects:

1 The enlistment of the interest of the contractor on behalf of of economy and promptness of execution;

2 Elimination of uncertainties and of hazard to the contractor;

3 Elimination, so far as possible, of opportunities for friction or favortism.

For the purpose of the report it was deemed advisable to divide contracts into three general classes:

1 Contracts for purchase of material and supplies upon which specifications can be nearly exact and few uncertainties are involved;

2 Contracts for construction in which conditions are accurately known and specifications may be exact, such as war vessels, guns, public buildings, etc.;

3 Contracts for construction where many uncertainties are ininvolved, such as character of material, weather conditions, etc.

In the purchase of materials it is desirable that so far as possible, these be made on the basis of test, so that the material purchased will be paid for in accordance with its value. The same principles can be usefully applied to some forms of construction. An example may be cited in the case of ship construction, where it is always desirable to obtain the highest practicable speed within reasonable limits of cost.

The field of structural work is the one to which the Committee gave most attention and in which there is most controversy concerning proper policies.

Much has been said regarding the desirability of standardizing Government contracts and the general tendency of the times is very properly in many fields towards standardization, but it is the opinion of the committee that taking into consideration all of the conditions to be met in the various departments, the extent to which governmental contracts can be standardized is limited and in general can be applied only to certain important general provisions of those contracts, such as the method of determining and enforcing damages, the method of settling disputes as to questions of fact, and the method of determining the compensation of the contractors.

In order, however, to facilitate and encourage bidding by responsible persons in the interest of economy to the Government and fairness to the public, such standardization as is possible should be secured through coöperation between the governmental departments.

In summarizing its work, the committee made the following recommendations:

1. That Government work be normally carried out through unit price, or lump-sum contracts, or by the purchase-and-hire method. Where none of the above methods are applicable to conditions, that the cost-plus method be used in which the contractor is refunded the actual cost of the work plus an accorded compensation which increases if the work is done below the estimated cost of the work, and decreases if the work costs more than estimated, but never sinks below zero.

2. That the failure of any bider to demonstrate to the satisfaction of the Government that he has adequate capital, experience, organization and plant effectively to carry out the work to be done, shall be sufficient cause to justify the conclusion that he is not a responsible bidder, and the consequent refusal of the Government to award him the contract.

3. That there be appointed by the President an inter-Departmental Board on Standardization of Contracts, consisting of one representative of each Government deparment engaged in construction. That this board recommend policies to govern in the standardization of contracts within each department. Each department should have a small board representative of each bureau engaged in construction, and should seek to unify and standardize contract practices within the Department, and the Chairman of these Departmental Boards might preferably constitute the inter-Departmental Board, which should only be advisory in character. That when the contracts of each department shall have been by itself thus standardized, that the inter-Departmental Board consider these contracts and make necessary recommendations to harmonize and secure, so far as feasible, uniformity of practice in the different departments.

4. That it be recognized as the preferable practice that government contracts be so drawn as to place the burden of unforseen contingencies, as far as possible, on the government in the interest of economy to the government in the long run and fairness to the bidders.

5. That all government officials shall recognize the importance of exerting the utmost efforts to make prompt partial payments on government contracts at reasonable intervals as stated in the contracts, for all services rendered and materials delivered by the contractor on the work that has been accepted by the government inspector.

6. That payment shall in all cases, as far as possible, be made by the official or agency directing the work and not by an outside accounting or finance agency, in order to avoid the burden on the contractor of delays in payments when made by such an agency not directly concerned with, or responsible for, the efficiency, economy and dispatch of the work.

7. That boards of arbitration be not in general used to adjust disputes as to facts relating to the execution of government contracts; but that the contractor be given the right of appeal to each of the superiors and the official directing the work, up to the chief of the bureau who may in his dis-

cretion appoint a disinterested board of arbitration to determine the facts. In important cases, the contractor should have the right of appeal to the head of department.

8. That deductions for non-completion of contracts on time, so far as practicable, be in the form of liquidated damages and be limited as nearly as possible to the actual damages estimated in advance; that an interpretation of this clause should be made to insure substantial justice, both to the contractor and to the Government in a spirit of liberality. The decision as to the imposition of the liquidated damages should rest in all cases with the technical or professional official or agency directing the work, and not with the clerical or accounting agency.

9. That the Government should take no cognizance of subcontractors further than to see that the principal contractors make prompt payment for all services rendered and materials furnished by the subcontractors. That the disbursing officer may suspend payments to the principal contractor until this is done.

Engineers Are Requested to Provide Contracts Stipulating Abidance by Decisions of National Board of Jurisdictional Awards

In making public the report of Rudolph P. Miller, F.A.E.S. representative on the National Board of Jurisdictional Awards in the Building Industry, L. W. Wallace, Secretary of the American Engineering Council emphasizes the fact that Mr. Miller's report shows that the National Board of Jurisdictional Awards has been instrumental in reducing the number of jurisdictional strikes in the building industry in the United States. Mr. Wallace also asks that the F.A.E.S. use its influence towards securing greater recognition of the important decisions made by the Board.

The function of the Board is the settling of controversies between various labor organizations. Mr. Miller's account of the meeting of February 6 to 9, 1922 is of great interest and a résumé of the outstanding features are given here.

In two disputes before it, the Board made awards as follows: first, the erection of grain hoppers and spouts was conceded to the sheet-metal workers when the metal is ten gage or thinner and to the iron workers when thicker than ten gage; and second, elevator constructors were permitted to hoist, lower and place new elevator machinery, iron workers handling the transport of this machinery to the building in which it is to be erected. A third dispute between iron workers and bricklayers regarding the erection of derricks for setting stone was held over for a future meeting.

One troublesome situation created by the carpenters was given careful consideration by the Board for a day and a half. The carpenters do not abide by the Board's award to the sheet-metal workers of the work of setting hollow metal doors. This caused great embarrassment and a committee of the board was appointed to draw up a resolution regarding this situation. This resolution is given in part below as it makes a direct recommendation to the engineering profession:

Your committee appointed to outline a procedure to be followed in clearing up the situation created by the failure or refusal of the United Brotherhood of Carpenters and Joiners to conform to the decisions of your Board, as brought to your attention by a committee of the Associated General Contractors, has given careful consideration to the matter.

Some of the decisions in question were rendered more than a year ago. All parties to the plan of the Jurisdictional Board, with the exception noted have endeavored to comply with all its decisions. Of these seventeen International Unions that constituted the Building Trades Department at the inception of the Board sixteen have unqualifiedly endorsed its work and supported its decisions. The seventeenth, namely the Carpenters' Union, has been suspended from the Building Trades Department because of its refusal to abide by those decisions. Some more definite action on the part of those loyal to the plan of the Jurisdictional Board seems desirable and necessary. Your committee therefore recommends the adoption of the following resolution:

Whereas, the United Brotherhood of Carpenters and Joiners of America has not been observing or conforming to the decisions of the National Board for Jurisdictional Awards in the Building Industry; and

Whereas, the attitude of that organization in failing to observe those decisions is seriously embarrassing owners, architects, engineers, contractors and workmen engaged in the building industry, and such a condition tends to increase costs and to cause delay and is detrimental to the public interest and the building industry in general; and

Whereas, all parties signatory to the plan of the Jurisdictional Board have been actively supporting the decisions of that Board, including sixteen of the seventeen International Unions constituting the Building Trades Department at the inception of the Board;

Resolved, That in order to correct the above mentioned conditions, the several signatories to the plan of this Board be urged to instruct their constituent members, each in its respective field as follows:

That the members of the American Institute of Architects and of the Federated American Engineering Societies insert in all specifications and contracts for building operations a stipulation that the decisions of the Jurisdictional Board shall be observed:

That the members of the Associated General Contractors and of the National Association of Building Trades Employers incorporate in their agreements with their subcontractors a provision that will secure a compliance with all decisions of the Jurisdictional Board and that the members thereof shall refuse employment to any local union or members thereof neglecting or refusing to abide by decisions of the Jurisdictional Board;

That the Building Trades Department shall instruct local councils to unseat any local union refusing compliance with such decisions, and that associated International Unions shall instruct their respective locals to extend neither recognition nor support until such time as delinquent locals accept and abide by all decisions of the Jurisdictional Board;

Resolved further, That this resolution shall be enforced as expeditiously as possible beginning with those localities in which the trouble appears to be most acute and where action seems most urgent and that all these signatories make special and united efforts toward securing general and complete compliance with all the decisions of the Jurisdictional Board; and

Resolved also, That as and when trouble in any locality is brought to the attention of any of the signatories such organization shall take the initiative in forming a general committee of representatives from all the signatories for the purpose of dealing with the situation in that locality.

The resolution as will be noted, urges the Federated American Engineering Societies to instruct all firms or individuals who are members of any of its constituent societies and who are engaged in building work, to insert in all specifications and contracts for building operations, a stipulation that the decisions of the Jurisdictional Board shall be observed. The American Institute of Architects has also been requested to do this with its members. There is no doubt but that this will help to an enormous extent, if not in the elimination of trouble coming from jurisdictional disputes. It is not uncommon at the present time, for architects and engineers to incorporate in their specifications, that disputes as to the meanings of those specifications shall be submitted to arbitration, and even in many cases to certain individuals named in the specifications as arbitrators.

NEWS OF OTHER SOCIETIES

Society of Industrial Engineers

The Influence of Industrial Engineering upon the Earnings of Capitol and Labor was the major subject of the eighth national convention of the Society of Industrial Engineers held at Detroit April 26, 27 and 28. Sessions were held by groups devoted to production, education, industrial relations, executive management, sales management and accounting.

In his presidential address, Prof. Joseph W. Roe, head of the department of industrial engineering of New York University, cited the report of the Committee on Elimination of Waste in Industry as evidencing the need of some method of measuring the effectiveness of management. He declared that there was more need for measuring the effectiveness of management than for measuring any other element in industry, and discussed the phases of it that are measurable and those that may not be.

Some other topics discussed were: The Influence of Industrial Engineering upon Manufacturing Plants, by E. Karl Wennerlund; How Industrial Engineering Serves the Chief Administrator, by Col. Benjamin A. Franklin; How Industrial Engineering May Serve the Executive, by E. W. Hulet; Practical Tests of Employees, by Henry C. Link; The Conservation of Material, by L. Moorehouse and E. J. Schmidt; The Conservation of Plant and Equipment, by F. H. Lowe and A. S. Cunningham; The Conservation of Labor, by Frank B. Gilbreth; Developments in Waste Elimination in the Field of Fatigue; by Norval A. Hawkins; Sales Management and Industrial Engineering, by Daniel B. Gauchet; and How Industrial Engineering Increases the Productivity of Each Industrial Unit at Reasonable Cost, by Parker A. Sowden.

The industrial relations' group discussed Experience with Employees' Representation Plans during the Periods of Business Depression; the managing executives' group discussed Managerial Red Tape; the accountants' group discussed With the Establishment of an Effective Budget Control, What Non-Essentials Can be Eliminated from Present Industrial Accounting, and the sales managers' group, Educating the Distributor.

A feature of the convention was the inspection of the big industrial plants of Detroit. An informal banquet was held on the evening of April 27 at which Matthew Woll, vice-president of the

American Federation of Labor spoke on How Industrial Engineering Can Serve Labor. President Roe presided at the banquet and other speakers included Robert B. Locke of the Federal Reserve Bank, Detroit, and Howard E. Coffin, vice-president of the Hudson Motor Co.

National Metal Trades Association

The program at the twenty-fourth annual convention of the National Metal Trades Association, held at the Hotel Astor, New York City, April 19 and 20, covered a wide range of subjects that dealt in a realistic way with many industrial problems of national and international importance.

Among the questions discussed were the stabilization of Europe and its bearing on domestic business; the relation between the railroads and their patrons; dealings between employers and employees; and coöperation between the farmer and the manufacturer. The report of a recent survey among plants of the members of the Association, which compared conditions as they exist at the present time, a year ago, and in 1914, was one of the most interesting features of the program. It revealed the fact that during the past year no strikes occurred at any of the plants of the members of the Association. The belief was expressed by the president, however, that the coming year, with its necessary further readjustment in wages, may not be so free from disturbances in the metal industry. It was predicted that normal wages will be considerably above the prewar plane. Additional information on this subject was brought out in an address on Facts and Fancies about Wages in Basic American Industries, by N. W. Alexander, of the National Industry Conference Board.

American Society of Civil Engineers

The Spring Meeting of the American Society of Civil Engineers was a three-day meeting devoted to Flood Problems. The meeting was held at Dayton, Ohio, on April 5, 6, and 7, with the technical sessions at the Engineers' Club, and was the first Spring Meeting which the Society has held.

The technical program was given at the three sessions held on the first day of the meeting. The remaining two days were devoted to excursions to nearby points of particular interest to those who were in attendance. The papers presented were: Flood Conditions in Canada, by J. G. Sullivan, President of the Engineering Institute of Canada; Floods on Small Streams Caused by Rainfalls of the Cloudburst Type, by Gerard H. Matthes; Standing Waves in Rivers, by N. C. Grover, chief hydraulic engineer, U. S. Geological Survey; Flood Problems in China, by John R. Freeman, President, A.S.C.E.; Methods in Flood Prevention in the Mississippi Valley, by J. A. Ockerson, member Mississippi River Commission; Relation of Flood Problems to Power and Irrigation Development in the Rocky Mountain States, by A. P. Davis, director U. S. Reclamation Service; Flood Prevention Methods on the Pacific Slope, by C. E. Grunsky, Vice-President A.S.C.E.; and Flood Problems of the Miami Valley and Their Solution, by Arthur E. Morgan and Charles H. Paul, former chief engineer and chief engineer, Miami Conservancy District.

On Thursday and Friday excursions were made to Englewood Dam, Huffman Dam, McCook Aviation Field, the National Cash Register Company's plant, which was the center of relief activities during the flood of 1913, and the American Rolling Mill plant at Middletown. Inspection was also made of the Dayton Channel Improvement work. The Englewood and Huffman Dams are two of the five hydraulic-fill dams that have been built for flood control in the Miami Valley. McCook Aviation Field is the center of research and engineering work in aeronautics for the U. S. Government.

At the dinner and smoker at the Miami Hotel on Thursday evening, Col. E. A. Deeds, president of the Dayton Engineers' Club and chairman of the Board of Directors of the Miami Conservancy District, spoke on Human Phases of the Miami Conservancy Project.

American Gear Manufacturers' Association

A three-day program devoted largely to the technical phases of gearmaking was carried out at the sixth annual convention of the American Gear Manufacturers Association held at the Lafayette Hotel, Buffalo, N. Y., April 20-22. Among the papers of a technical nature that were presented and discussed were: The Use of the Projection Comparator in Testing Gear Teeth (illustrated), by Ralph E. Flanders; Proportions of Industrial Gears, by G. E. Katzenmeyer; The Grinding of Gear Teeth and its Future, by R. S. Drummond; Good Hob Practice, by H. E. Harris; and Bevel Gears, by F. E. McMullen and T. M. Durkon.

Reports were delivered from the standardization committees but no definite action was taken on this phase of the work of the Association. George L. Markland, Jr., of the Philadelphia Gear Works, and R. P. Johnson, of the Worm Gear Co., Muncie, Ind., were the leaders of a general discussion on business conditions. The conditions of the automobile industry, particularly as they affect the gear-making trade, was one of the main topics discussed at this session. Although it was agreed that nothing approaching a business "boom" was to be expected, the general tone of the meeting was optimistic.

Book Notes

Abriss der Lehre von den Erzlagerstatten. By Richard Beck; prepared by Georg Berg. Gebruder Borntraeger, Berlin, 1922. Paper, 7×10 in., 408 pp., illus., $3.60.

During his latter years Dr. Beck had in mind the preparation of an abridgment of his well-known treatise on ore deposits which would be suitable as a college textbook and a survey of the principal information on the subject for use by geologists whose chief interests lie along other lines. With this in view, he had corrected and annotated a copy of the third edition of the treatise, when his death in 1919 made it necessary to entrust the preparation of the present work to Mr. Berg, one of his earliest assistants.

This outline is approximately one-third the size of the original work, which it follows in plan and arrangement. Condensation has been effected in the different chapters by bringing together the less important occurrences, that are interesting for geological or other reasons, as examples in a general description of the corresponding groups of deposits. The number of ore formations has been reduced by combining certain groups, and the chapter on epigenetic deposits has been shortened.

Analysis of Fuel, Gas, Water and Lubricants. By S. W. Parr. Third edition. McGraw-Hill Book Co., Inc., New York, 1922. Cloth, 6×8 in., 250 pp., illus., diagrams, tables, $2.50.

This book was originally published for use by students of mechanical engineering, and provided a course intended to help the engineer to a better understanding of the literature of the topics treated, and also to an appreciation and more intelligent use of data supplied by the chemist. The present edition has been expanded to meet the needs of students of chemistry as well. It contains a synopsis of the author's lectures on fuel, gas, water and lubricants, and a course in laboratory methods for their analysis.

Automatic Telephone Systems. By William Aitken. Vol. 1. Circuits and apparatus as used in the public services. Benn Brothers, Ltd., London, 1921. Cloth, 8×10 in., 282 pp., diagrams, 25s.

The great mass of detail and the complicated circuit diagrams required to present this subject make special treatment necessary, if a treatise is to be suited to the needs of students. This book attempts to present the subject in intelligible form by rearranging the diagrams, eliminating unnecessary crossing lines, simplifying the form and presenting them in such a way as to show the relationship of the system as a whole. To accomplish these ends a large page and a new system of describing the diagrams, which consists in numbering a circuit from end to end with the same system, have been used. The book covers the whole subject. The principal commercial systems and other less known systems of promise are described.

Continuous Wave Wireless Telegraphy. By B. E. G. Mittell. (Pitman's technical primers.) Sir Isaac Pitman & Sons, Ltd., London and New York, 1922. Cloth, 4×7 in., 110 pp., illus., $0.85.

This little book is offered as an introduction to radiotelegraphy from the engineer's point of view. It avoids the use of mathematics and plunges directly into the subject without a preliminary discourse upon electricity or the development of mechanical analogies. Special attention, so far as space permits, is given to the Poulsen arc and to the construction of tall aerial structures, and useful references to important papers are given throughout the book.

THE ENGINEERING INDEX

(Registered United States, Great Britain and Canada.)

THE ENGINEERING INDEX presents each month, in conveniently classified form, items descriptive of the articles appearing in the current issues of the world's engineering and scientific press of particular interest to mechanical engineers. At the end of the year the monthly installments are combined along with items dealing with civil, electrical, mining and other branches of engineering, and published in book form, this annual volume having regularly appeared since 1906. In the preparation of the Index by the engineering staff of The American Society of Mechanical Engineers some 1200 technical publications received by the Engineering Societies Library (New York) are regularly reviewed, thus bringing the great resources of that library to the entire engineering profession.

Photoprint copies (white printing on a black background) of any of the articles listed in the Index may be obtained at a price of 25 cents a page. When ordering photoprints identify the article by quoting from the Index item: (1) Title of article; (2) Name of periodical in which it appeared; (3) Volume, number, and date of publication of periodical; (4) Page numbers. A remittance of 25 cents a page should accompany the order. Orders should be sent to the Engineering Societies Library, 29 West 39th Street, New York.

ACCIDENT PREVENTION

Methods and Limitations. Limitations and New Methods of Accident Prevention (Grenzen und neue Wege der Unfallverhutung), Karl Hartmann. Zeit. des Vereines deutscher Ingenieure, vol. 66, no. 8, Feb. 25, 1922, pp 186–188 Conditional and unconditional protection Technical and economic limitations Development of protective regulations. Necessity of coöperation between machine constructor, manager and workman.

AERIAL PHOTOGRAPHY

Fairchild Camera. Aerial Photography, W. L. Hamilton. Aerial Age, vol 15, nos 1 and 2, Mar. 13 and 20, 1922, pp 6-7 and 36-38, 7 figs. Mar. 13: Discusses a map of New York taken from an airplane, and the Fairchild camera with which it was made Mar. 20: Discusses several examples of successful aerial photography.

AERONAUTICAL INSTRUMENTS

Telecompass. A Solution of the Problem of Determining Position in an Airplane (Une solution du problème de l'orientation en avion), Industrie Électrique, vol. 31, no. 710, Jan. 25, 1922, pp. 25–27, 4 figs. Mechanical and electrical description of the telecompass, and its use.

AIR COMPRESSORS

Modern. Modern Compressors (Les compresseurs modernes), A. Lambrette. Technique Moderne, vol. 13, nos. 11 and 12, Nov and Dec 1921, and vol. 14, no. 2, Feb. 1922, pp. 468–474, 502–510 and 59–63, 48 figs. Discusses single-acting, double-acting, monocylindric-two-phase, two-stage, and multiple-stage compressors; inlet and outlet valves; lubrication; play in bearings and connecting rod; etc.

Portable Oil-Engine-Driven. A Portable Air Compressor for Industrial Use (Groupe motocompresseur transportable pour usages industriels), J.-A. Calmettes. Génie Civil, vol. 80, no 4, Jan. 28, 1922, pp. 87–88, 2 figs. Describes the Diatto compressor driven by an oil engine, for drilling, boring, etc.

AIR CONDITIONING

Gas-Absorption Device. A New Device for Gas Absorption, H. E. Robertson Chem. Age (N. Y.), vol. 30, no. 2, Feb. 1922, pp. 59–60, 2 figs. Construction and operation of new air conditioner and purifier adapted to many industrial processes involving handling of gases.

AIRCRAFT

Designing Parts. Improved Method for Designing Aircraft Parts, Roy G. Miller and F. E. Seiler, Jr. Aviation, vol. 12, no 13, Mar. 27, 1922, pp. 366–367, 2 figs. Practical method for determination of elements of irregular structural sections.

Fuels. See GASOLINE.

Research. Research from the Designers', Constructors' and Users' Points of View, Fred M. Green. Flight, vol. 14, no. 8, Feb. 23, 1922, pp. 121–122. Discusses problems of wing surface, power required, metal construction, calculations of stresses, engine design, fuels, navigation, etc. (Abstract.) Paper read before Air Conference, 1922. See also Aerial Age, vol. 15, nos. 1 and 3, Mar 13 and 27, 1922, pp. 8–9 and 61–62.

Specialized. Specialized Aircraft, W. D. Beatty. Aeronautical Jl., vol. 26, no 135, Mar. 1922, pp. 92–101 and (discussion) 101–107. How heavier-than-air aircraft has been developed in England on specialized lines, with special reference to comfort of passenger.

AIRCRAFT CONSTRUCTION MATERIALS

Fabric Coverings. Deterioration of Aeroplane Fabrics, Fr. Wendt. Aerial Age, vol. 14, no. 25, Feb. 27, 1922, p. 593. 32nd report of German Experimental Inst. for Aviation at Berlin-Adlershof. Series of experiments were carried out on effect of weathering on cloth covering of airplane wings and fuselages. From Zeit. für Flugtechnik u. Motorluftschiffahrt, Nov. 30, 1921, p. 325.

AIRPLANE ENGINES

Developments. Recent Aircraft Engine Developments, C. Fayette Taylor. Soc. Automotive Engrs. Jl., vol. 10, no. 3, Mar. 1922, pp. 204–206, 5 figs. Outlines most important advances in aircraft engines since signing of armistice. Use of anti-knock compounds; aircraft-engine size and cooling; aircraft powerplant refinement.

Maybach. Performance of Maybach 300-Horsepower Airplane Engine. Nat. Advisory Committee for Aeronautics, report no. 134, 1922, 11 pp., 24 figs. Deals with results of test made in altitude chamber of Bur. of Standards. From standpoint of thermal efficiency, full-load performance is excellent at densities corresponding to altitudes up to 15,000 ft.; at part load thermal efficiency is low.

AIRPLANE PROPELLERS

Performance. Graphic Calculation of Performances of Air Propellers According to Model Tests (Zeichnerische Berechnung der Leistungen von Luftschrauben nach Modellversuchen), Adolf Rohrbach. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol. 13, no. 5, Mar. 15, 1922, pp. 61–63, 2 figs. New nomogram is developed to supplement graphic calculations of Durand and Lesley in U. S. Nat. Advisory Committee for Aeronautics Reports nos. 14, 30, 64 and 109.

AIRPLANES

Aerofoils. Properties of Two Aeromarine Aerofoils, B. V. Korvin-Kroukovsky. Aviation, vol. 12, no. 11, Mar. 13, 1922, pp. 314–315, 2 figs. Development of two high-lift wings for use on large aircraft, particularly adapted for performance at large incidence.

Center of Pressure Coefficients for Aerofoils at High Speeds, W. S. Diehl. Nat. Advisory Committee for Aeronautics Technical Notes, no. 25, Apr. 1922 2 pp., 3 figs. It has been customary to calculate strength of rear wing beam for "high-speed" condition on assumption that center of pressure was at 0.50 of wing chord. It is shown that this assumption is not justified.

Altimeter and Air Speed Indicator. The Dugit Altimeter and Air Speed Indicator, J. H. Blakely. Aviation, vol. 12, no. 13, Mar. 27, 1922, pp. 371–372, 3 figs. Discusses instruments based on application of Archimedean spiral which give increased precision and uniform sensitiveness. Translated from Génie Civil.

Commercial. A Gloucestershire Goods Type Commercial Aeroplane. Flight, vol. 14, no. 6, Feb. 9, 1922, pp. 87–88, 1 fig. Tractor biplane, fitted with Rolls-Royce Eagle engine; 360 hp.; 1,600 lb. goods-carrying capacity.

Electric Cables, Directing by. Directing Airplanes by Electric Cables (Le guidage des avions par cables électriques), P. Franck and A. Volmerange. Aeronautique, vol. 4, no. 33, Feb. 1922, pp. 39–47, 17 figs. Describes method by Loth, based on method of directing ships by electric cable, by which landing in fog and "taking of position" are made possible.

Fuel Level Indicator. The Smith Petrol Level Indicator. Flight, vol. 14, no. 8 Feb. 23, 1922, p. 124, 2 figs. Describes new device by S. Smith & Sons, Ltd., Lond., special features of which are simplicity both in construction and operation. Adaptable also for use on reservoirs, storage tanks, etc.

German Commercial. The L. F. G. Commercial Airplane Type V 13 (Das L. F. G.-Verkehrsflugzeug Type V 13). Motorwagen, vol. 25, no. 6, Feb. 28, 1922, pp. 119–120, 2 figs. Characteristics of the Strela, for 2 or 4 passengers: Weight empty, 1460 kg.; total weight, 2128 kg.; max. span, 17.5 mm.; max. length, 10.9 m.; max. height, 3.88 m.; engine, 185-hp. Benz or Bavarian Motor Works engine, or 220-hp. Benz or Mercedes.

1000-Hp. Napier Cub. Harnessing 1,000 Horse Power. Flight, vol. 14, no. 8, Feb. 23, 1922, pp. 118–119, 7 figs. Describes the 1000-hp. Napier "Cub."

Parachutes. See PARACHUTES.

Research. Research With Full Sized Airplanes, F. H. Norton. Tech. Eng. News, vol. 2, no. 9, Mar. 1922, pp. 240–241, 3 figs. Describes some free flight problems recently investigated by Nat. Advisory Committee for Aeronautics, at Langley Field.

Seaplanes. See SEAPLANES.

Speed Calculation in Flight. Graphic Calculation of Airplane Speeds in Straight and Circling Flight (Zeichnerische Berechnung der Geschwindigkeiten von Flugzeugen im Geradeaus- und Kurvenflug), Adolf Rohrbach. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol. 13, no. 5, Mar. 15, 1922, pp. 59–61, 2 figs. Presents charts and describes method of calculation.

Waco Model 4. The Waco Model 4. Aerial Age Weekly, vol. 15, no. 2, Mar. 20, 1922, pp. 32–34, 2 figs. Describes four-place biplane of Weaver Aircraft Co. of Lorain, Ohio; Curtiss Ox-5 motor; 84 m.p.h. at 1050 r.p.m.

AIRSHIPS

Development and Possibilities. Airships, G. H. Scott. Aerial Age, vol. 14, no. 25, Feb. 27, 1922, pp. 590–593. Airship activities in various countries; technical position of modern British airship, including hull, fabric, engines, safety, weather conditions, and mooring mast; value of airships for defense. Paper read before British Air Conference.

Drag of Hull. The Drag of C Class Airship Hull with Varying Length of Cylindric Midships, A. F. Zahm, H. R. Smith and G. C. Hill. Nat. Advisory Committee for Aeronautics, Report no. 138, 1921, 10 pp., 6 figs. A model of C class airship hull, when severed at its major section and provided with cylindric mid-body of variable length, had its air resistance increased about in proportion to length of mid-body up to 3 diameters, and in about manner to be expected from increase of skin friction on this variable length. For greater length drag increased less and less rapidly.

Model Tests. Hydrostatic Test of an Airship Model. Nat. Advisory Committee for Aeronautics Technical Notes, no. 87, Mar. 1922, 15 pp., 8 figs. on supp. plates. Airship model made by Goodyear Rubber Co. was filled with water and suspended from beam and deformations of envelope studied under following conditions: both ballonets empty; forward ballonet filled with air; rear ballonet filled with air; and both ballonets filled with air.

R 38 Accident. British Report on the Loss of Airship R38. Aviation, vol. 12, no. 11, Mar. 13, 1922, pp. 311–312. Findings of Aernautical Research

Speed. The Choice of the Speed of an Airship, Max M. Munk. Nat. Advisory Committee for Aeronautics Technical Notes, no. 89, Mar. 1922, 8 pp., 2 figs. Presents fairly simple rules which it is claimed may be of advantage if reasonably applied.

ALCOHOL

Dilute Solutions. The Vapour Pressures of Dilute Alcohol Solutions, R. Thomas. Soc. Chem. Industry Jl., vol. 41, no 4, Feb. 28, 1922, pp. 33T–34T, 2 figs. Describes rapid method of determining partial pressures of alcohol and water in an aqueous solution of former.

ALLOY STEELS

Vibrac. Vibrac Steel. Motor Transport, vol. 34, no. 888, Mar. 6, 1922, p. 287, 1 fig. Describes properties and tests of new steel produced by Armstrong, Whitworth & Co., which is proof against temper-brittleness.

ALLOYS

Aluminum. See ALUMINUM ALLOYS.

Copper. See COPPER ALLOYS.

Ternary and Quaternary. The Graphic Presentation of Ternary and Quaternary Alloys (Die graphische Darstellung von Dreistoff- und Vierstoff-Legierungen), W. Hommel. Zeit. fur Metallkunde, vol. 13, nos. 13, 14 and 15, Oct. Nov. and Dec. 1921, pp. 456–465, 511–518 and 565–569, 22 figs. Development of new method for diagrammatic presentation of such alloys. The concentration and melting temperature for each alloy can be read immediately in diagram. Construction of diagrams for different systems.

Treatment. Modern Metal Alloys and Their Treatment (Neuere Metallegierungen und ihre Verarbeitung), Willy Hacker. Elektrotechnischer Anzeiger, vol. 39, nos. 2, 3 and 5, Jan. 4, 5 and 10, 1922, pp. 8–10, 14–16 and 35–37. Review of modern German processes for preparation and treatment of alloys.

ALUMINUM ALLOYS

Failures. Some Cases of Failure in "Aluminium" Alloys, W. Rosenhain. Inst. of Metals Advance Paper for meeting Mar. 9, 1922, 4 pp., 2 figs.; also Engineering, vol. 113, no. 2932, Mar. 10, 1922, p. 308, 2 figs. Discusses two examples of failures showing that materials which undergo serious growth, distortion, and disintegration in course of service, are not aluminum alloys in ordinary sense of that term, but materials of essentially different type.

Research. On Some Alloys of Aluminum, Walter Rosenhain and Sydney L. Archbutt. Instn. Mech. Engrs. Proc., no. 7, 1921, pp. 699–725 and (discussion) pp. 727–771. Report to Alloys Research Committee representing result of organized work of practically whole staff of Metallurgical Dept. of Nat. Physical Laboratory. Deals with cast and wrought alloys, permanence and constitution of alloys.

Zinc and Aluminum. A Further Study of the Alloys of Aluminum and Zinc, D. Hanson and Marie L. V. Gayler. Inst. of Metals Advance Paper for meeting Mar. 9, 1922, 28 pp., 29 figs. Account of investigation. Deals with determination of the solidus; constitution of solid alloys; the constituent beta; age-hardening of constituent beta and gamma. Photomicrographs.

AMMONIA COMPRESSORS

Losses. Losses in Ammonia Compressors, S. F. Smith. Refrig. World, vol. 57, no. 3, Mar. 1922, pp. 25–26. The five ways in which losses occur in compression machine and conditions which control same. The two-stage compressor and its field. Paper read before Mountain States Ice Manufacturers Assn.

Starterless Induction Motors for. Starterless Induction Motors for Ammonia Compressors, J. Lebovici. A.S.R.E. Jl., vol. 8, no. 5, Mar. 1922, pp. 398–402 and (discussion) 402–404, 7 figs. Combines favorable characteristic of squirrel cage and slip ring types, and makes ideal drive for ammonia compressors using up to 150 hp.

APPRENTICES, TRAINING OF

System, Rock Island Arsenal. Apprenticeship System at Rock Island Arsenal, William Baumbeck. Am. Mach., vol. 56, no. 14, Apr. 6, 1922, pp. 512–514, 6 figs. Devices for teaching. Use of slide rule. Action of gear teeth and selection of proper views for drawings. Outline of courses.

ASH HANDLING

Hydraulic Disposal System. Handling Ashes by Sluicing, C. C. Lance. Power, vol. 55, no. 13, Mar. 28, 1922, pp. 503–504, 1 fig. Calumet and Hecla Mining Co. power plant at Lake Linden, Mich., reduces ash handling costs by hydraulic system of ash disposal.

AUTOMOBILE ENGINES

Air Cooling. Air-Cooling Progress in U. S. A., Harold F. Blanchard. Autocar, vol 48, no. 1376, Mar. 4, 1922, pp. 355–359, 8 figs. Economy in operation important feature. Discusses air cooling as applied to Franklin, Holmes, 6-cylinder Fox, and twin-three D.A.C. cars, and explains how cooling draught is induced

Buda. A Good Example of Modern Engine Design, J. Edward Schipper Automotive Industries, vol. 46, no. 13, Mar. 30, 1922, pp. 699–700, 1 fig. New model of Buda engine designed for light commercial trucks and similar applications, but of heavy-duty type and similar in general design to other engines of same make. Compression ratio, 4.35 to 1.

Carburetors. See CARBURETORS.

Crankshafts. See CRANKSHAFST.

Cylinders. Some Aspects of Air-Cooled Cylinder Design and Development, S. D. Heron. Soc. Automotive Engrs. Jl., vol. 10, no. 4, Apr. 1922, pp. 231–260, 35 figs. Design and development of modern high-output air-cooled cylinder. Deals primarily with problems of aircraft cylinder of approximately 40 b.hp.

Development. Aircraft Engine Experience as a Basis for Automobile Engine Development, H. Dechamps. Automotive Industries, vol. 46, no. 11, Mar. 16, 1922, pp. 611–613. Super-compression and over-dimensioning of engines as an aid to fuel economy.

Fuel Economy. Relation Between Fluid Friction and Transmission Efficiency, Neil MacCoull. Soc. Automotive Engrs. Jl., vol. 10, no. 3, Mar. 1922, pp. 193–199, 16 figs. Experiments to determine mechanical losses, including data from E. H. Lockwood's experiments at Yale. Possibilities for increasing fuel economy of a motor vehicle. See also Lubrication, vol. 8, no. 1, Jan. 1922, pp. 1–8, 15 figs.

Ignition, Automatic. Automatic Ignition Advance. Autocar, vol. 48, no. 1376, Mar. 4, 1922, pp. 362–363, 1 fig. Describes mechanism to provide automatic spark advance by depression in inlet pipe, which is very great when throttle is almost closed, but grows less with increase of engine speed, and mechanical compensation moving with throttle mechanism.

Increasing Power Obtainable. The Super-Power Engine, G. Funck. Autocar, vol. 48, no. 1377, Mar. 11, 1922, pp. 395–400, 13 figs. Deals with means of increasing power obtainable from engine of given cubical capacity other than those ordinarily employed.

Manifold Design. Manifold Vaporization and Exhaust-Gas Temperatures, O. C. Berry and C. S. Kegerreis. Soc. Automotive Engrs. Jl., vol. 10, no. 3, Mar. 1922, pp. 171–176, 10 figs. Discusses low volatility of fuel for internal-combustion engines as cause of uneconomical utilization of fuel and of engine maintenance troubles. Tests carried out.

Stutz. Powerplant in New Stutz Model Incorporates Many Changes, J. Edward Schipper. Automotive Industries, vol. 46, no. 14, Apr. 6, 1922, pp. 750–751, 6 figs. Lighter pistons, redesign of jackets and cylinder head, better fuel vaporizing means, heavier crankshaft, machined combustion chambers, etc.

Two-Stroke. An Investigation of Certain Aspects of the Two-Stroke Engine for Automobile Vehicles, F. W. Lanchester and R. H. Pearsall. Automobile Engr., vol. 12, no. 160, Feb. 1922, pp. 55–62, 16 figs. Investigation of principal factors controlling performance of internal-combustion engines functioning on two-stroke cycle, especially small size engines of simplest forms adapted to work at comparatively high revolution-speeds. Paper before Instn. Automobile Engrs.

AUTOMOBILE FUELS

Alcohol. The Use of Alcohol as Fuel in Exported Vehicles, Herbert Chase. Automotive Industries, vol. 46, no. 14, Apr. 6, 1922, pp. 771–773, 1 fig. Use of alcohol in Spanish-American countries because of less cost, and adaptation of vehicles for use of alcohol. Discusses problems met in its use and suggests remedies.

[See also GASOLINE.]

AUTOMOBILES

Austro-Daimler. The 17/60-Hp. Anstro-Daimler Six-Cylinder Car Type AD 617 (Der 17/60 PS-Anstro-Daimler-Sechszylinder-Wagen, Type AD 617). Allgemeine Automobil-Zeitung, vol. 23, no. 4, Jan. 28, 1922, pp. 28–30, 7 figs. Dimensions: Max. length, 4.625 m.; max. width, 1.685 m.; max. height, 1.56 m.; wheelbase, 3.45 m.; gage, 1.36 m.; weight of chassis, 1240 kg. Details of engine.

Bianchi 12–20 Hp. The 12–20 Hp. Bianchi Chassis. Automobile Engr., vol. 12, no. 161, Mar. 1922, pp. 66–71, 12 figs. Describes engine, clutch, gearbox, etc., of small car made by Bianchi Motors, Ltd., Milan.

Bodies, Manufacture of. The Efficient Production Automobile Bodies, G. W. Eastwood. Eng. Production, vol. 4, nos. 74 and 75, Mar. 2 and 9, 1922, pp. 200–202 and 221–224, 18 figs. Construction methods. Paper presented before Instn. Production Engrs. See also discussion of paper in same journal, vol. 4, no. 76, Mar. 16, 1922, pp. 218–250.

Brakes. Developing a Method for Testing Brake-Linings, S. von Ammon. Soc. Automotive Engrs. Jl., vol. 10, no. 3, Mar. 1922, pp. 153–162, 23 figs. Describes equipment developed and methods used for tests; coefficient of friction; endurance tests with cooled drum; severe-service test with uncooled drum; etc.

Passenger-Car Brakes, J. Edward Schipper. Soc. Automotive Engrs. Jl., vol. 10, no. 4, Apr. 1922, pp. 273–289, 29 figs. Comprehensive survey of present braking practice and outline of future requirements and possibilities; design factors; future of brakes.

The Perrot-Hallot Brake (Die Perrot-Hallot-Bremse), Claus Syrlin. Allgemeine Automobil Zeitung, vol. 23, no. 1, Jan. 7, 1922, pp. 33–34, 2 figs. Details and principle of automobile brake developed by Hallot and Perrot, tests with which recently carried out under auspices of Royal English Automobile Club showed excellent results.

Gear Boxes. Improvements in Gear-box Design, H. F. L. Orcutt. Automotive Industries, vol. 46, nos. 9, 10 and 11, Mar. 2, 9 and 16, 1922, pp. 511–514, 563–565 and 617–621, 5 figs. Mar. 2: Points out some of usual defects and outlines methods of improvement. Mar. 9: Methods employed to carry on special gear-box gear tests. Describes new gear-tooth grinding process. Mar. 16: Factors in production of gear boxes, and suggestions for improvements in design. Condensed from paper read before Instn. Automobile Engrs.

German Szawe. German Car of Novel Design Employs Many Aluminum Parts, Benno R. Dierfeld. Automotive Industries, vol. 46, no. 13, Mar. 30, 1922, pp. 701–706, 20 figs. Uses six-cylinder, 2.44 by 5.51-in. aluminum alloy engine with thin steel liners cast in block. Outstanding features are an automatic gearshift, and rear axle housing casting and pistons of silumin. Built by Szabo & Wechselmann, Berlin, principally for export trade.

Hubs and Pistons. Tooling Equipment for Automobile Hubs and Pistons, Ralph E. Flanders. Machy. (N. Y.), vol. 28, no. 8, Apr. 1922, pp. 640–644, 16 figs. Describes tools and operations.

Miniature Four-Cylinder. Miniature "Fours." Autocar, vol. 48, no. 1378, Mar. 18, 1922, pp. 431–435, 9 figs. Description of some of best known of modern four-cylinder engines having piston displacements of less than 1,000 cc.

Modern Plant Design. Designing a Modern Automobile Plant, Paul L. Battey. Iron Age, vol. 109, nos. 10 and 11, Mar. 9 and 16, 1922, pp. 652–656 and 713, 14 figs. What is involved in relations of departments and in many services now demanded. View of future in industrial developments. Providing power, heating, water supply and other services. Details of plant and manufacturing procedure of the Willys Corp., Elizabeth, N. J. Based on paper presented before Am.Soc.Mech.Engrs.

Repair Shops. Service in a "White" Station, Fred. H. Colvin. Am. Mach., vol. 56, no. 12, Mar. 23, 1922, pp. 429–432, 9 figs. Layout of Newark, N. J., service station of White Motor Co. Eliminating time waste. Layout of stockroom. Exchange of worn or damaged parts. Facilities for handling motors and other parts.

16–20 Hp. Cubitt. The 16–20–Hp. Cubitt Chassis. Automobile Engr., vol. 12, no. 160, Feb. 1922, pp. 34–40, 15 figs. Low-priced vehicle built on quantity production lines. Described engine, clutch, gearbox, transmission brake, transmission and rear axle, suspension, etc.

Star. New Durant Product Makes Good Impression, Herbert Chase. Automotive Industries, vol. 46, no. 11, Mar. 16, 1922, pp. 601–604, 7 figs. Describes new car built for Star Company. Has 102-in. wheelbase; pump circulation; long, semi-eleptic springs; storage battery; etc.; 35 hp. at 2,500 r.p.m.

Steam. A Steam Car That Is Different. Sci. Am., vol. 126, no. 4, Apr. 1922, p. 262, 4 figs. Details of new Coats steam car having gas-car control and finish with steam-car smoothness.

Suspension. A New Suspension System. Auto, vol. 27, no. 7, Feb. 16, 1922, p. 136, 1 fig. Some details of the Gattie device in which helical springs are utilized.

240-Hp. Racing. A 240-Hp. Car For Brooklands. Autocar, vol. 48, no. 1376, Mar. 4, 1922, p. 351, 2 figs. Fitted with Benz aero engine, Hartford shock absorbers and Rudge-Whitworth wire wheels.

AVIATION

Aerial Transportation. Aerial Transport Today and Tomorrow, W. A. Bristow. Aerial Age, vol. 14, no. 26, Mar. 6, 1922, pp. 616–618 and 627 and vol. 15, no. 2, Mar. 20, 1922, pp. 35 and 38. Also abstract in Flight, Feb. 16, 1922, p. 99. Discusses present situation depending on subsidies of some sort, the building up of merchant air fleets as main reliance for military air fleets, and increased passenger traffic required.

Civil. The Air Conference. Flight, vol. 14, no. 6, Feb. 9, 1922, pp. 83–86, 2 figs. Summary of Lord Gorell's paper on Civil Aviation, discussing factors of successful development, service and civil sides, progress, necessity for more research work, cross-channel services, imperial air services, air mails, policy of subsidization, etc.

Marking Aerodromes. Marking Aerodromes, P. James. Aerial Age, vol. 14, no. 25, Feb. 27, 1922, pp. 586 and 588. Necessity of adopting system of markers for giving direction for starting and landing and of indicating good part of field. Methods hitherto employed and methods now proposed. From Premier Congrès Internationale de la Navigation Aérienne, Paris, Nov. 1921, vol. 2, pp. 115–118.

AXLES

Milling Eccentric Keyways In. Device for Milling Eccentric Keyways in Axles of Locomotives After the Axles are Pressed Into the Wheels. Ry. & Locomotive Eng., vol. 35, no. 3, Mar. 1922, pp. 58–59, 3 figs. Details of construction and application.

B

BALANCING

Rotating Masses. Notes on Balancing Rotating Masses, J. W. Rogers. Mech. World, vol. 71, nos. 1832 and 1833, Feb. 10 and 17, 1922, pp. 106–107 and 124–125, 6 figs. Feb. 10: Statical and dynamical balancing. Feb. 17: Describes Martin rotor balancing machine, whose application affords quick, safe and inexpensive method of balancing all types of rotary bodies and gives very accurate results.

BEARINGS, ROLLER

Street Cars. Roller Bearings in the Municipal Street-Railway Cars of Hagen (Germany) (Rollenlager im Betriebe der Hagener Strassenbahn), K. Pforte. Verkehrstechnik, vol. 29, no. 7, Feb. 17, 1922, pp. 80–83, 4 figs. Describes Jaeger type of roller bearings adopted by municipal street railway as substitute for uneconomic journal bearing for motors and axle bearings, and points out their value in reducing cost and increasing safety. Advantages over ball bearings.

BEARINGS, THRUST

Michell. The Michell Bearing Machy (Lond), vol. 19, no 495, Mar 23, 1922, pp 765-766, 4 figs Application.

BELTING

Power Transmission by. Power Transmission by Belting, W G Dunkley Eng & Indus Management, vol 7, no. 10, Mar 23 1922 pp 280-281, 2 figs. Describes common faults which are met with in works, and suggests methods by which they may be satisfactorily overcome Notes on belt design, stresses and tension

BENDING MACHINES

Boiler-Plate. A New Boiler-Plate Bending Machine of Vertical Type with Electric Drive (Eine neue Kesselblechbiegemaschine stehender Anordnung mit elektrischem Antrieb), Hugo Becker Schiffbau, vol 23, no 22-23, Mar 1-8, 1922, pp. 690-693, 6 figs. Describes new type of bending press for boiler plate which is claimed to show marked improvements and advantages over older types

BOILER FEEDWATER

Treatment. Advantages of Treating Locomotive Feed Water. Boiler Maker, vol 22, no. 3, Mar 1922, pp. 66-68 Quality of boiler water, treatment to prevent scale and plants designed for the purpose; gives questionnaire on water treatment. To be presented at 1922 meeting Master Boiler Makers' Assn.

Treated Water Improves Locomotive Performance, W. A. Powanall. Ry Mech. Engr , vol. 96, no. 4, Apr. 1922, pp. 191-192 Systematic methods of boiler water treatment by soda ash process.

BOILER OPERATION

Efficient. The Expectation of Efficiency of Steam Boiler Operation, Hugh R. Carr Power Plant Eng , vol 26, no 7, Apr. 1, 1922, pp 357-360, 2 figs Discusses variables entering into the question, viz : type of draft, combustion rate, coal, ratio of heating to grate surface, point of maximum heat intensity. Proposes empirical curves for determining efficiency with fair degree of accuracy

Rating Percentage. Percentage of Boiler Rating. Power, vol. 55, no. 14, Apr. 4 1922, pp 531-532. What it means and how it is figured Presents table for simplifying computations

BOILERS

Adaptation to Low-Grade Fuel. Reconstruction of Coke Sectional Boilers for the Burning of Substitute Fuels (Umstellung von Koksgliederkesseln auf Ersatsbrennstoffe), H. Pradel. Braunkohle, vol. 20, no. 45, Feb. 11, 1922 pp. 705-711, 12 figs. Details of improvements in boilers by German boilermakers designed for use of low-grade fuel.

Ambitubular. Ambitubular Boiler (Chaudière ambitubulaire), C. Anguenot Arts et Metiers, vol. 74, no. 15, Dec. 1921, pp. 357-360 2 figs Describes boiler combining water tubes and fire tubes and advantages of both.

Design and Operation. Steam Boilers, F. W Dean. N. E. Water Works Assn Jl , vol 36, no. 1, Mar. 1922, pp. 115-139 and (discussion) pp. 139-140, 5 figs. Notes on internally and externally fired boilers, fire-tube and water-tube boilers, workmanship; baffles; method of taking steam from boilers, height of boilers above floor, height of bridge walls, locomotive-type boilers, feedwater regulators, temperature of escaping gases mechanical and hand stokers, pulverized coal, oil fuel, feeding boilers, etc.

Electrically Heated. Electrically Heated Boilers (Elektrodampfkessel), H. Schneider Archiv. fur Wärmewirtschaft, vol. 3, no 2, Feb 1922, pp 27-28, 5 figs. Comparison with steam generation with coal firing. Types of electrically heated boilers

Heat-Loss Determination. A New Method of Determining Heat Losses by Means of the Combustible Gas in the Exhaust Gases of Boilers (Ein neues Verfahren zur Bestimmung der Wärmeverluste durch brennbares Gas in den Abgasen der Kesselfeuer), O. I. Hansen. Zeit. des Bayerischen Revisions-Vereins, vol. 26, nos. 1, 2 and 3, Jan. 15, 31 and Feb. 15, 1922, pp. 3-5, 13 15 and 21 22, 4 figs. Describes method and apparatus with which it is possible to determine heat loss with sufficient accuracy. Account of tests carried out by K. E. Nielsen in Copenhagen (Denmark) gas works.

High-Pressure. The Thermo-Dynamics of Extra High Pressure Steam in Connection with Power and Heat Economics, O. H. Hartmann. Eng. Progress, vol. 3, no. 3, Mar 1922, pp. 45 48, 7 figs. Describes vertical-tube boiler for pressure of 60 atmos. developed by Wilhelm Schmidt, which can generate steam at this atmosphere and up to temperature of 450 deg. cent. Tests with extra-high-pressure steam engines, and importance of these engines for heat economics. Possibilities of application of extra-high-pressure steam in connection with combined power and heating installations.

Locomotive. See LOCOMOTIVE BOILERS

Low-Pressure Gas in Oil-Field. Use of Low-Pressure Gas Burners in Oil-Field Boilers, M. P. Youker. U. S. Bur. of Mines Reports of Investigations, serial no. 2329, Feb. 1922, 8 pp. Résumé of report on possibilities of using low-pressure gas to generate steam for drilling purposes and on types of gas burners which would be best for this purpose.

Welding. Commercial Welding on High Pressure Boilers, Edward H. Heidel. Can Machy , vol. 27, no. 12, Mar. 23, 1922, pp. 27-28, 5 figs. Procedure and rules to be followed in welding boilers, autogenous welding of locomotives, etc. Paper read before Am. Welding Soc.

BOILERS, WATER-TUBE

Design. Standard Rules Governing The Construction of Water Tube Boilers Shipbldg & Shipg Rec , vol. 19, no 11, Mar 16, 1922, p. 345. Deals with Part V of Standard Conditions for Design and Construction of Marine Boilers and Shafting, prepared by British Marine Engineering Design and Construction Committee.

Reliability. The Reliability of Water-Tube Boilers Shipbldg & Shipg. Rec , vol. 19, no 10 Mar 9, 1922 p 299 Editorial dealing with explosion which occurred in one of the water-tube boilers of the Berengaria

BOLTS

Tightening by Use of Liquid Air. Experimental Use of Liquid Air and Explosives for Tightening Body-Bound Bolts, H. L. Whittemore. Am. Mach , vol 56, no 14, Apr. 6, 1922, pp. 524 526 Cylindrical and taper bolts contracted by liquid air and allowed to expand after insertion. Cylindrical bolts expanded in place by explosives.

BORING TOOLS

Chart for Determining Pressure. Chart for Determining the Pressure Exerted by Boring Tools, J. B. Conway. Am. Mach., vol. 56, no. 13, Mar. 30, 1922, pp. 476-478, 1 fig. Describes construction and operation of chart. Determination of end thrust and pressure due to cutting. Table for values of feed to 0 7 power.

BRAKES

Freight-Train. Continuous Brake for Long Freight Trains (Le freinage continu des longs trains de marchandises), J. Netter. Le Génie Civil, vol. 79, nos 26 and 27, Dec. 24 and 31, 1921, pp. 557 561 and 585-590, 28 figs. Dec. 24: Discusses tests in progress by Commission of French Public Works. Describes situation before and after war, also the Westinghouse triple-valve brake. Dec. 31. The Kunze-Knorr and Lipkowski compressed-air brakes and the Clayton-Hardy vacuum brake. Results of tests carried out.

BRASS

Forgings, Manufacture of. The Manufacture of Brass Forgings, C. T. Roder. Iron Age, vol. 109, no. 13, Mar. 30, 1922, pp. 857-858, 2 figs. Called also die pressing or hot forging. Details of process developed in United States during war. Physical and other properties.

Plasticity Under Compression. Plasticity of Brass Rods Under Percussive Compression, Fr. Doerinckel and Julius Trockels. Raw Material, vol. 5, no. 2, Mar. 1922, pp. 58-62, 16 figs. Discusses occurrence of flow in compressed brass by hydraulic compression of bars, showing that at red-heat vortex motions ensue by pressure in brass block. From Zeit. für Metallkunde.

Season Cracking. Further Studies in Season-Cracking and Its Prevention. Condenser Tubes, H. Moore and S. Beckinsale. Inst. of Metals Advance Paper for meeting Mar. 8, 1922, 22 pp., 11 figs. Record of work done in consequence of suggestion made by George Goodwin, of application to Admiralty condenser tubes of low-temperature annealing recommended for removal of internal stress in brass. See also (abstract) in Engineering vol. 113, no. 2933, Mar. 17, 1922, pp. 337-340, 11 figs.; and Metal Industry (Lond.), vol. 20, no. 13, Mar. 31, 1922, pp. 298-302, 6 figs.

BROACHES

Design. The Design of Pull Broaches, J. Labensky and Palmer Hutchinson. Machy. (N. Y.), vol. 28, no. 8, Apr. 1922, pp. 615-617, 4 figs. Depth of cut, pitch, length, shape of teeth. Methods of attaching broaches to machines.

BUSES

Trolley. The Operation of a Self-Contained Trolley Omnibus System, J. B. Parker. Tramway & Ry. World, vol. 51, no. 13, Mar. 16, 1922, pp. 117-123, 13 figs. Describes operation of system controlled by Tees-side Railless Traction Board, and gives operating costs of new trolley buses.

C

CABLEWAYS

Aerial. Aerial Cableways (Les transporteurs aériens à cables), Cretin. Génie Civil, vol. 80, nos. 4 and 5, Jan. 28 and Feb. 4, 1922, pp. 75-79 and 103-105, 15 figs. Jan. 28: Discusses analytical calculations with examples. Feb. 4: Tension of cableways and calculation of loads.

CAMS

Design. Design of Cams (Einiges uber die Nockenscheiben der Motoren), Arthur Balog. Wirtschaftsmotor, no. 12, Dec. 25, 1921, pp. 19-21, 5 figs. It is shown how, for different types of engines (for example, Diesel engines), a uniform basis can be developed for design of uniform, easily made cams.

CAR WHEELS

Chilled-Iron, Manufacture. Car Wheel Manufacture Revolutionized, Gilbert L. Lacher. Iron Age, vol. 109, nos. 13 and 14, Mar. 30 and Apr. 6, 1922, pp. 847-852 and 939-943, 8 figs. Describes practice at plant of Griffin Wheel Co. at Council Bluffs, Iowa. Notes on mechanical molding; charging and handling of cupolas; sand preparation; core making and baking.

Flange Welding. Getting Wheel Mileage Without a Lathe. Elec. Traction, vol. 18, no. 3, Mar. 1922, pp. 214-215, 6 figs. Utilization of welding and cutting torch instead of wheel-turning lathe by Terre Haute, Indianapolis and Eastern Traction Co.

Machining. Machining and Mounting Wheels and Axles, Charles Petrain Ry. Mech. Engr., vol. 96, no. 3, Mar. 1922, pp. 148 150, 1 fig. Gaging-worn axles and rolled-steel wheels; welding cast steel wheels (Abstract.) Paper read before Car Foremen's Assn of Chicago.

CARBURETORS

German Types. Carburetors Exhibited at the German Automobile Show 1921 (Die Vergaser auf der Deutschen Automobil-Ausstellung 1921), Joh Menzel Allgemeine Automobil Zeitung, vol 22, nos. 43, 44, 45, 46, 47 and 49 Oct 22, 29, Nov 5, 12, 19 and Dec. 3, 1921, pp 24 25, 28 30, 33 35, 34 35, 28 29 and 32 34, 29 figs. Details, advantages and disadvantages of types exhibited.

Problems and Design. The Relation of Carburetion to Fuel Economy, J. N. Golten. Automotive Industries, vol. 46, nos. 12 and 13, Mar. 23 and 30, 1922, pp. 666 669 and 711 717, 14 figs. Mar. 23 Functions of carbureting system; metering characteristics of ideal carburetor; pulsating air flow; carburetor problems and design. Mar. 30 Vaporization from theoretical and practical standpoint.

CARS

British Works. The Nottingham Works of Cammel Laird and Co , Limited. Engineer, vol. 133, no 3451, Mar. 10, 1922, pp. 268 270, 12 figs. partly on p 272. Describes shops, equipment and practice of works for production of railway rolling stock. See also Engineering, vol. 113, no. 2932, Mar. 10, 1922, pp. 292 294, 4 figs.

Hose Connector, Automatic. Recent Changes in American Hose Connectors. Ry. Mech. Engr., vol. 96, no. 3, Mar. 1922, pp. 141-143, 4 figs. Manufactured by Am. Automatic Connector Co., Cleveland, Ohio. Passenger heads interlocked under pressure; permanently attached freight interchange adapter.

CARS, COAL

Gondola. C. M. and St. P. Ry. Sets An Example in Good Car Design. Ry. Rev., vol. 70, no. 12, Mar. 25, 1922, pp. 415-420, 5 figs. Particulars of design of new gondola cars of Chicago Milwaukee & St. Paul; 50 tons capacity; weight, 40,400 lb.

CARS, FREIGHT

Interchange. On the Question of Interchange of Rolling Stock (all countries except America), M. Charron. Int. Ry. Assn. Bul., vol. 4, no. 3, Mar. 1922, pp. 479 535. Report on interchange of goods rolling stock (freight cars), and penalty charges in case of delay in return of that stock; rules to be adopted in relations between railways themselves; rules to be adopted in relations between railways and consignors and consignees.

CASE-HARDENING

Chemical Energizers. More About Chemical Energizers, H. B. Knowlton. Forging & Heat Treating, vol. 8, no. 3, Mar. 1922, pp. 141-145, 2 figs. Action of chemical energizers during carburizing process; tests to prove relative efficiency of certain chemicals and methods of manufacture of compounds.

CAST IRON

Welding. The Dependability of Cast Iron Welding, G. O. Carter. Iron Age, vol. 109, no. 14, Apr. 6, 1922, pp. 928-930, 8 figs. Preheating and annealing essential; correct preparation of casting. Some results attained commercially. (Abstract.) Paper read before Cleveland section, Am. Welding Soc.

CASTING

Centrifugal. Producing Centrifugal Castings, H. Cole Estep. Iron Trade Rev., vol. 70, no. 13, Mar. 30, 1922, pp. 887-892, 19 figs. Process employed in England for making gray iron and nonferrous castings. Micrographs show effect of centrifugal force. See also Foundry, vol. 50, no. 6, Mar. 15, 1922, pp. 217-222, 19 figs.

Chilled. Inversed Chill Casting and Related Phenomena (Umgekehrter Hartguss und verwandte Erscheinungen), W. Heike. Stahl u. Eisen, vol. 42, no. 9, Mar. 2, 1922, pp. 325-332, 24 figs. Examples of occurrences. So-called black fracture. Inversed chill casting attributed to differences in pressure.

CASTINGS

Ingot Mold. How Ingot Mold Castings Are Made. Foundry, vol. 50, no. 6, Mar. 15, 1922, pp. 229-235, 11 figs. Practice at plant of Hanna Furnace Co. at Dover, Ohio, having capacity of 500 tons a day.

Internal-Combustion Engines. British Motor Castings Methods—I-VI, Ben Shaw and James Edgar. Foundry, vol. 50, nos. 1, 2, 3, 4, 5 and 6, Jan. 1, 15, Feb. 1, 15, Mar. 1 and 15, 1922, pp. 11-16, 57-62, 102-107, 149-152, 198-202 and 236-239, 129 figs. Jan. 1: Making of a wooden pattern of a water-jacketed cylinder block for an internal-combustion engine. Jan. 15: Preparation of mold; core problems; valve faces molded down; artificially bonded sand strengthened with rods and vented with wax. Feb. 1: Making of patterns and core-boxes for a typical crankcase casting. Feb. 15: Molding procedure dependent on whether machine is to be used or not. Patterns gated to cause aluminum to flow quietly. Mar. 1: Types of smaller castings for internal-combustion engines. Mar. 15: Methods for molding water-inlet, front-cover and oil-pan castings.

Looms. Loom Castings Tax Molder's Skill, H. R. Simonds. Foundry, vol. 50, no. 6, Mar. 15, 1922, pp. 223-224, 2 figs. Two core prints were attached to strengthen pattern as well as to form seat for longitudinal core at one side and pocket core at other end of intricate casting shown.

CENTRAL STATIONS

Modern Construction. Modern Tendencies in Central Station Construction (Les tendances moderns dans la construction des centrales), F. Sconmanne. Société Belge des Électriciens, vol. 35, Sept.-Oct. and Nov.-Dec. 1921, pp. 211–224 and 252–257, and vol. 36, Jan.-Feb. 1922, pp. 19–25. Sept.-Oct.: Discusses choice in the power of units, boilers and economizers, steam piping, coal and ash handling, automatic stoking, forced draft, etc. Nov.-Dec.: Deals with machinery room, including turbines, alternators, condensers. Jan.-Feb.: Switchboard arrangements, including bus-bars and distribution of current.

Montreal Street Railway. The Main Plant of the Montreal Street Railway, T. H. Fenner. Power House, vol. 15, no. 6, Mar. 20, 1922, pp. 15–21, 10 figs. Describes Hochelaga power house and its equipment, including 22 water-tube boilers, turbo generators, direct connected reciprocating units of large size, etc.

Superpower. The Superpower System. Am. Inst. Elec. Engrs., vol. 42, no. 4, Apr. 1922, pp. 287–297. Two articles dealing with essential elements of superpower plant. The first, by Henry Flood, Jr., deals with steam-electric plants proposed by system; and second, by L. E. Imlay, deals with hydroelectric plants, transmission system and superpower system as a whole.

CHAIN DRIVE

Inverted- and Roller-Tooth Type. Chain Drives, A. Bayliss. Eng. & Indus. Management, vol. 7, no. 10, Mar. 23, 1922, pp. 282–286, 3 figs. Practical notes concerning two main types, viz. (1) inverted tooth and (2) roller tooth type. Describes rocker-joint chain.

CHROME STEEL

Etching Medium for Tungsten and. New Etching Medium for Chromium and Tungsten Steels. Iron Age, vol. 109, no. 11, Mar. 23, 1922, p. 790, 1 fig. Special solution for detecting presence of carbides. Valuable as applied to high-speed steels. Translated from article by K. Daeves in Stahl u. Eisen, Sept. 8, 1921.

Nickel-Molybdenum and. Chrome and Nickel-Molybdenum Steels, C. N. Dawe. Iron Age, vol. 109, no. 11, Mar. 16, 1922, pp. 725–728, 2 figs. Comparison with other alloy steels for automobile use. Nickel molybdenum for case-hardening. (Abstract.) Paper presented at Soc. of Automotive Industries.

CHUCKING MACHINES

Automatic, for Railway Shops. An Improved Automatic Machine For Railway Shops. Ry. Gaz., vol. 36, no. 9, Mar. 3, 1922, pp. 351–352, 2 figs. Describes the Victor automatic chucking machine, made by W. G. Armstrong, Whitworth & Co., Ltd.

CLUTCHES

Friction. A New Friction Clutch of Radical Design Developed in France. Automotive Industries, vol. 46, no. 11, Mar. 16, 1922, pp. 609–610, 1 fig. Clutch is engaged by increasing foot pressure.

COAL HANDLING

Automatic. Automatic Coal and Ash Handling Plant, E. W. L. Nicol. Chem. Age (Lond.), vol. 6, no. 141, Feb. 25, 1922, pp. 234–236, 7 figs. Describes rotary truck tippler, the U link conveyor, and the "sandwich" system of feeding coke and coal.

COMBUSTION

Air Required for. Air Required for Combustion of Gases in Steel Plants, R. T. Haslam and A. F. Spiehler. Blast Furnace & Steel Plant, vol. 10, no. 3, Mar. 1922, pp. 174–175, 1 fig. Determination of amount of air required for combustion of various gases from B.t.u. content of gas.

Control Apparatus. Combustion Regulators (Verbrennungsregler). Elektrotechnischer Anzeiger, vol. 39, nos. 35 and 37, Mar. 2 and 7, 1922, pp. 268–270 and 293–294, 13 figs. Describes new governors patented by G. Ph. Haass, Obrigheim, Germany, consisting of undergrate-blast and swivel-damper regulators which are attached to furnace and boiler.

Modern Apparatus for Control of Cumbustion and Evaporation (Les appareils modernes destinés au controle de la combustion et de la vaporisation), Lucien Maugé. Bul. de la Société d'Encouragement pour l'Industrie Nationale, vol. 133, no. 10, Dec. 1921, pp 1237–1321, 84 figs. Describes apparatus at international exposition of Office Central de Chauffe Rationelle, including gas-analysis apparatus, thermometers and pyrometers, pressure gages, steam meters, etc.

CONDENSERS, STEAM

Low-Level Multi-Jet. New Condensers for an Old Turbine. Power, vol. 55, no. 13, Mar. 28, 1922, pp. 492–493. Baltimore plant makes unique application of low-level, multi-jet condensers.

CONVEYORS

Chemical Industry. Conveying Machinery in the Chemcial Industry, George Frederick Zimmer. Chem. Age (Lond.), vol. 6, no. 141, Feb. 25, 1922, pp. 230–233, 12 figs. Fundamental principles which should underlie economical employment of labor-saving devices; review of most suitable mechanical handling devices for specific purposes of chemical industry.

Portable. Handling with Portable Conveyors, E. J. Tournier. Gas Age-Rec., vol. 49, no. 11, Mar. 18, 1922, pp. 317–323, 18 figs. Discusses development of machinery for moving material, up to most recent designs of apparatus for the purpose.

Types. Conveying and Elevating Machinery, Gardner Mitchell. Instn. Mech. Engrs. Proc., vol. 2, no. 8, Dec. 1921, pp. 895–916 and (discussion) pp. 931–969, 16 figs. Deals with different types of conveyors and elevators.

COPPER ALLOYS

Cupro-Nickel, Cold Work in. The Internal Mechanism of Cold-Work and Recrystallization in Cupro-Nickel, Frank Adcock. Inst. of Metals Advance Paper for meeting Mar. 8, 1922, 20 pp., 45 figs. Results of experiments on commercial cupro-nickel (copper 80 per cent, nickel 20 per cent). See also Engineering, vol. 113, nos. 2932 and 2933, Mar. 10 and 17, 1922, pp. 305–308 and 340–342, 45 figs.

COST ACCOUNTING

Drop-Forge Plants. Forge Shop Burden and Estimating, George H. Koskey. Forging & Heat Treating, vol. 8, no. 3, Mar. 1922, pp. 136–140, 2 figs. Advocates machine-hour basis for burden system in place of flat burden rate over whole shop.

Paper-Mill Power Plant. Power Costs in Paper Mill Accounting, B. C. Gause. Paper, vol. 29, no. 26, Mar. 1, 1922, pp. 7–8. Classification of power expenses; apportionment of costs; overhead charges; elements of cost.

Predetermination of Costs. The Predetermination of Costs, J. McD. Cronin. Indus. Management, vol. 63, no. 4, Apr. 1922, pp. 221–224. Writer points out some of more glaring defects in commonly accepted methods of cost accounting and advantages derived from installation of modern methods. Notes on predetermination of burden factor, labor and material factor.

Sewage Works. Keeping Records and Accounts for a Small Sewage Works, Percy Lamb. Eng. & Contracting, vol. 57, no. 13, Mar. 29, 1922, pp. 294–295, 1 fig. Importance of accounting methods; meteorological records; method of recording results; working costs, fuel, repairs, etc. (Abstract.) From 1921 Proc. of Assn. of Mgrs. of Sewage Disposal Works.

COTTON GINS

Machinery. Cotton-Ginning Machinery, Solomon E. Gillespie. Mech. Eng., vol. 44, no. 4, Apr. 1922, pp. 231–236 and 242, 15 figs. Describes apparatus developed for mechanically handling raw seed cotton, removing lint therefrom, and forming it into shape suitable for delivery to baling press. Cotton-ginning process, and latest developments of various devices employed.

COTTON MILLS

Electric Drive. Electric Drive in Cotton Mills, George Wrigley. Gen. Elec. Rev., vol. 25, no. 2, Feb. 1922, pp. 102–110, 9 figs. Discusses electrical and individual drive and control of machines and explains operation performed by each type of machine.

COUPLINGS

Machining Large Flexible. Machining Large Flexible Couplings. Machy. (Lond.), vol. 19, no. 491, Feb. 23, 1922, pp. 632–634, 6 figs. Describes practice of Wm. Beardmore & Co., Ltd., Dalmuir, in machining large flexible couplings of a type extensively used in marine propulsion work.

CRANES

Electric Controllers. Electric Crane Controllers, J. F. Schnable. Am. Inst. Elec. Engrs. Jl., vol. 41, no. 4, Apr. 1922, pp. 313–319, 5 figs. Deals with problems concerning selection of ohmic values for resistors, and connection arrangements and resistance values involved in dynamic braking control of lowering loads.

Motor-Operated. Auxiliary Electrical Equipment for Motor-Operated Cranes, H. W. Eastwood. Am. Inst. Elec. Engrs., Jl. vol. 41, no. 4, Apr. 1922, pp. 319–328. Deals with brakes, overload protective panels and limit switches. Discusses various service requirements and describes several available types of magnet brakes and their particular fields of application.

Shipyard. Shipyard Cranes (Krananlagen für Schiffbau und Schiffsmaschinenbau), H. Kessner and Karl Böttcher. Schiffbau, vol. 23, no. 22–23, Mar. 1–8, 1922, pp. 645–669, 42 figs. Review of development in Germany in past 20 years in crane installations for construction of ships and ship machinery.

Shipyard Cableway Cranes (Hellingkabelkrane), Martin Bruckmann. Schiffbau, vol. 23, no. 22–23, Mar. 1–8, 1922, pp. 669–675, 10 figs. Describes Bleichert system and its installation in Hamburg shipyards. Economic advantages.

CRANKSHAFTS

Machining Automobile. Machining Automobile Crankshafts, Fred H. Colvin. Am. Mach., vol. 56, no. 14, Apr. 6, 1922, pp. 504–507, 11 figs. Approved methods of machining and balancing crankshafts. Data as to wheels for various grades of steels. Wheel speed and wear.

CUPOLAS

Center-Blast Tuyere. The Bottom or Center-Blast Cupola Tuyere, Geo O. Vair. Can. Foundryman, vol. 13, no 3, Mar. 1922, p. 25, 1 fig. Advantages and disadvantages compared with side-blast.

Flameless. Flameless Cupolas with Overgrate Blast (Flammenloser Kupolofen mit Oberwind). Zeit. für die gesamte Giessereipraxis, vol. 43, no. 5, Feb. 4, 1922, pp. 62–64. Suggestions for design and proper care of cupolas.

D

DIES

Forming and Assembling. Forming and Assembling Dies for Roll Cam, W. B. Greenleaf. Machy. (N. Y.), vol. 28, no. 8, Apr. 1922, pp. 618–619, 5 figs. Describes dies used in making parts for roll cam, including combination blanking and forming die; blanking, piercing, and flanging die; and assembling die.

DIESEL ENGINES

American Marine. Building American Diesel-Engines. Motorship, vol. 8, no. 4, Apr. 1922, pp. 259–263, 8 figs. Details of McIntosh & Seymour plant at Auburn, N. Y., where oil engines for 25 successful merchant ships have been turned out.

German Marine. Demonstration of the Deutsche Werke Engine. Motorship, vol. 8, no. 4, Apr. 1922, pp. 264–266, 10 figs. New 950-shaft hp. Diesel marine engine exhibited shortly after completing 7-day non-stop run. Four-cycle, crosshead, single-acting type, direct reversible.

1900-Hp. High-Speed. Investigation of a 1900-Hp. High-Speed Diesel Engine in a Cotton Spinning Plant in Augsburg (Germany) (Untersuchung einer 1900 PSe-Schnelläufer-Dieselmaschine in der Baumwollspinnerei am Stadtbach in Augsburg), H. Deinlein. Zeit. des Bayerischen Revisions-Vereins, vol. 26, no. 4, Feb. 28, 1922, pp. 25–27, 2 figs. Results of investigation carried out by Bavarian Revisions-Verein confirmed guaranteed efficiency of engine.

Nobel 1600-Hp. Tests on a 1600-Hp. Nobel Diesel Engine (Untersuchung eines 1600 PSe-Nobel-Dieselmotors). A. Rosburg. Zeit. des Vereines deutscher Ingenieure, vol. 66, no. 6, Feb. 11, 1922, pp. 137–139, 15 figs. Investigation of two-cycle Diesel engine described in same journal (no. 3, 1922) with regard to efficiency, fuel consumption, relation of indicated work to useful work, compressor, scavenging-pump and friction work at different speeds and load conditions. Test results.

DRILLING MACHINES

Multiple-Spindle Drill Heads. Multiple-spindle Drill Heads, George Hey. Machy. (Lond.), vol. 19, nos. 491 and 493, Feb. 23 and Mar. 9, 1922, pp. 621–627 and 702–705, 21 figs. Feb. 23: Discusses shortcomings of multiple-spindle drill heads, and describes design of multiple-spindle adjustable type, for drilling of high tensile steels. Mar. 9: Fixed center type of drill head.

DROP FORGING

Practice. Drop-Forging Practice, J. H. Nelson. Soc. Automotive Engrs. Jl., vol. 10, no. 3, Mar. 1922, pp. 207–211. Discusses practice from standpoint of materials used; advocates more rigid inspection and testing of raw products to determine their fitness for use in making automatic forgings. Tabular data of chemical analyses and physical tests made on a 0.40 to 0.50 per cent carbon steel.

Perfecting. Perfecting a Drop Forging, J. H. G. Williams. Forging & Heat Treating, vol. 8, no. 3, Mar. 1922, pp. 152–155, 14 figs. Discusses various defects in drop forging and how to remedy them.

E

ELECTRIC DRIVE

Woolen Mills. Electric Driving in Scottish Woolen Mills, A. W. Stevenson. Electrician, vol. 88, no. 2284, Feb. 24, 1922, pp. 217–219, 4 figs. Discusses electric and steam drive, and describes the various processes to produce finished wool product.

ELECTRIC FURNACES

Basic-Hearth. Basic Hearth Electric Furnace for Cast Iron, George K. Elliott. Can. Foundryman, vol. 12, nos. 10 and 11, Oct. and Nov. 1921, pp. 41–42 and 44 and pp. 32–34. Advantages of electricity over other fuel, from the standpoint of clean, sound metal and uniform chemical analysis. Paper read before Instn. British Foundrymen.

Brass. Brass Melting in Electric Furnaces (Messingschmelzen im elektrischen Ofen) Herbert Hein. Metall-Technik, vol. 48, no. 2, Jan. 7, 1922, pp. 9–11, 4 figs. Describes Röchling-Rodenhauser system of two-phase induction furnace with auxiliary heating rings.

Fiat. The Fiat Electric Furnace (Il forno elettrico "Fiat"). Electtrotecnica, vol. 9, no. 4, Feb. 5, 1922, pp. 74–79, 16 figs. Describes furnace invented by Masera, of Acciaierie Fiat, which can be used advantageously for special steels in small quantities and for ordinary steel in large quantities.

Smelting. Smelting Iron Ore Electrically, R. Durrer. Iron Trade Rev., vol. 70, no. 12, Mar. 23, 1922, pp. 827–828, 1 fig. Comparison of operating conditions in standard and electric blast furnaces. Causes of hot and cold working. Relation of direct and indirect reduction in electric furnaces. Translated from Stahl u. Eisen, June 2, 1921.

Tool-Steel Melting. Electric Tool Steel Melting Practice, W. J. and S. Stuart Green. Three important factors: Acid or basic bottoms; liquid or cold charges and double or single voltage. Electric furnace in other roles.

ELECTRIC LOCOMOTIVES

Monophase. Monophase Locomotive for Swiss Federal Railway. Ry. Elec. Engr., vol. 13, no. 2, Feb. 1922, pp. 45–50, 8 figs. Detailed description of locomotive designed for both freight and passenger service. (Abstract.) From Bulletin of Brown, Boveri & Co.

Passenger, Chile. Electric Passenger Locomotives for Chilean State Rys. Ry. Rev., vol. 70, no. 9, Mar. 4, 1922, pp. 291–293, 2 figs. Describes the two types of locomotives for new electrified line between Valparaiso and Santiago.

Regeneration Characteristic Curves. Regeneration Characteristic Curves of Direct-Current Locomotives, C. A. Atwell Elec Jl., vol 19, no 3, Mar. 1922, pp. 113–116, 7 figs Explains plotting of curves and regeneration characteristics

ELECTRIC RAILWAYS

Braking, Regenerative Regenerative Braking and Single-Phase Commutator Motors. R Nordefeldt. Electrician, vol 88, nos 2287 and 2288, Mar 17 and 24, 1922, pp. 312–314 and 340 341, 10 figs. Discusses regenerative braking on electric railways, especially problems arising in single-phase traction, and distinguishes between regenerative braking as a speed check on long down grades, and as required for bringing train to a standstill Describes methods of single-phase that have been used or suggested and advantages and disadvantages of each. Abstract from Teknisk Tidskrift

Development and Equipment. Electric Traction for Steam Railroads Ry Elec Engr, vol. 13, no. 2, Feb. 1922 pp. 57 61, 1 fig Tendencies of practice in United States. Limitations and advantages of equipment used

Italy. Electric Traction (La questione della trazione elettrica), Alfredo Donati. Elettrotecnica, vol. 9, nos 4 and 5, Feb 5 and 15, 1922, pp. 81 91 and 104–112, 23 figs. Feb. 5 Discusses Italian developments since 1899 and gives details of three-phase system adopted for state railways. Feb. 15. Technical data of Valtellina, Monza-Lecco, Milano-Varese-Porto Ceresio, Torino-Modane and other lines, and technical and financial results of Italian electrification. Translated from Bul de l'Association Internationale des Chemins de Fer, Sept. 1921, pp. 1199.

Mountain Districts. Electrical Operation in Mountain Districts, Frank Rusch. Ry. Age, vol. 72, no. 13, Apr. 1, 1922, pp. 833 834 Outline of operations on Chicago, Milwaukee & St. Paul. (Abstract) From Milwaukee Employees' Mag, Mar. 1922.

Trackless Transportation vs. Trackless Transportation and the Electric Railway. Elec. Ry. Jl, vol. 59, no. 9, Mar. 4, 1922, pp. 355–362. Abstracts of papers read at Midyear Meeting of Am Elec Ry. Assn. How the Maryland Commission Acts, E H. Whitman; City Service and British Conditions, C. D. Emmons; Auto Bus and Truck Good as Interurban Feeders, Harry Reid; and California Situation Regarding Rail and Trackless Transporation, Paul Shoup.

ELECTRIC WELDING

Boiler Tubes. Electrically Safe Ending Boiler Tubes, J. J. Sullivan. Ry. Elec. Engr., vol 13, no. 3, Mar. 1922, pp. 102–103, 2 figs. Describes practice on Nashville, Chattanooga & St. Louis, at Nashville shops, cost of electric welding.

Steel Construction. Electric Welding Applied to Steel Construction, With Special Reference to Ships, A. T. Wall. Shipbldg. & Shipg. Rec., vol. 19, nos. 8 and 9, Feb. 23 and Mar. 2, 1922, pp. 239–242 and 271–272, 14 figs. Discusses various ways in which electric welding is being applied to ship construction and indicates further possibilities in this connection for steel structures; reasonable precautions to be taken in carrying out work. Paper read before Instn. Mech. Engrs.

ELECTRIC WELDING, ARC

Applications. Applications of Electric Arc Welding E. Wanamaker. Ry. Elec. Engr, vol. 12, no. 10, Oct. 1921, pp. 376–382. Successful welding calls for three prime requisites: Proper equipment, proper materials, and necessary skill.

Cast Iron. Arc Welding of Cast Iron, A. R. Allard. Welding Engr., vol. 7, no. 3, Mar. 1922, pp. 19–22 and 40–41, 8 figs. Characteristics of cast iron which influence its weldability and general procedure for welding it. Paper read before Am Welding Soc.

Cyc-Arc Process. The Cyc-Arc Process of Automatic Electric Welding, L. J. Steele and H. Martin. Instn. Elec. Engrs. Jl., vol. 60, no 306, Feb. 1922, pp. 236–244. Discussion of paper which appeared in same journal in Jan. 1922 number, pp. 136–162.

Railway Shops. Arc Welding in Railway Shops, S. E. Mason. Elec. Ry. Jl., vol. 59, no. 11, Mar. 18, 1922, pp. 446–448, 5 figs Repairs to rolling stock equipment can be made without removal from cars so that large savings in labor and material result.

Shipbuilding, Application to. On the Application of Electric Arc Welding to Two Vessels, M. Harmiishi. Am. Welding Soc. Jl., vol. 1, no. 2, Feb 1922, pp. 31–41, 5 figs Account of author's experience with arc welding in converting a steam trawler into an oil lighter, and work on a steel self-floating caisson for drydock in Japanese dockyard. (Abstract.) Paper read before Japanese Soc. of Shipbuilders.

EMPLOYEES, TRAINING OF

Extension Work in Factory. Taking University Training to the Factory, Paul M. Atkins. Indus. Management, vol. 63, no 4, Apr 1922, pp. 239–242. Describes plan consisting of university extension work in individual plant.

Manufacture. The Training of Workers in Manufacture, J. V. L. Morris. Am. Mach., vol. 56, no. 11, Mar. 16, 1922, pp. 400–402 Coöperative employment of engineering students Length of shop period. Courses on technical subjects. Advanced shop and school instruction.

ENGINEERING

Human Activity. Engineering as a Human Activity, H. E. Riggs. Eng. News-Rec., vol. 86, no. 11, Mar. 16, 1922, p. 435. Deals with some of non-technical sides of engineering. Jobs and how to get them; fees and how to maintain them; etc. (Abstract.) Paper before Mech. Eng. Soc.

ENGINEERS

Code of Ethics. A Code of Ethics for Engineers Min & Metallurgy, no. 183, Mar 1922 p 46 Presents code and method of interpreting and administering it, recommended by Joint Committee on Code of Ethics

Licensing Advantages and Disadvantages of Licensing Engineers, B. R. Gottsberger. Min. & Metallurgy, no 183, Mar. 1922, pp 47–50. Arguments for and against licensing.

Practicing. How Practicing Engineers May Sell Their Services. Eng. News-Rec., vol. 88, no. 13, Mar. 30, 1922, pp. 523–524. Methods of securing clientele and increasing business. Abstract of two papers at Conference of Practising Engrs under auspices of Am. Assn. Engrs.

ENGINEHOUSES

Cold Climate. Novel Engine Facilities for a Cold Climate. Ry. Mech. Engr., vol. 96, no 3, Mar. 1922, pp. 163–164, 2 figs. Describes rectangular enginehouse with radial tracks and enclosed turntable of Canadian National Railways.

F

FACTORIES

Size and Efficiency. Considerations on Factory Size and Efficiency, Henry Baker. Engineer, vol. 133, no. 3455, Mar. 17, 1922, pp. 292–294, 2 figs. Writer concludes that factory just large enough to be well under control of one man probably represents most efficient size at present time. Future of large factory depends on overcoming difficulties of management.

FACTORY MANAGEMENT

See INDUSTRIAL MANAGEMENT.

FATIGUE

Industrial. Fatigue in Industry, Eugene Lyman Fisk Am. Jl. Public Health, vol. 12, no. 3, Mar. 1922, pp. 212–217. Reviews literature discussing kinds of fatigue and how to measure fatigue

FIREPROOFING

Wood and Textures. Protection Against Fire By Fireproofing Textures and Woods (La protection contre l'incendie par l'ignifugation des tissus et des bois), André Kling and Daniel Florentin. Génie Civil, vol. 80, nos. 8 and 9, Feb. 25 and Mar. 4, 1922, pp. 180–183 and 202–204. Feb. 25: Discusses especially fireproofing of stage decoration materials and describes two processes for the purpose. Mar. 4: Fireproofing of woods and methods employed; tests made to show their efficiency.

FLIGHT

Controls Locked. Airplane Flight With Locked Controls (Vol de l'avion à commandes bloquees), Alavrac. Aerophile, vol. 30, no. 1–2, Jan. 1–15, 1921, pp. 9–11, 1 fig. Mathematical treatment of movement of center of gravity of a solid in a resisting medium.

Human Physical Sensations. The Human Machine in Aviation, Edward C. Schneider. Aerial Age, vol. 15, no. 4, Apr. 3, 1922, pp. 82–83, 86 and 95. Discusses human physical sensations in flying, including those caused by high altitude, insufficient oxygen, etc. Reprinted from Yale Rev.

Optical Delusions. Perception of Space and Location in Flight (Die Raumempfindung im Fluge), Friedrich Noltenius. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol. 13, no. 3, Feb. 15, 1922, pp. 31–33. Discusses frequently occurring optical delusions of airmen in flight that earth or horizon is out of place.

Soaring. Engineless Flight (Le vol des avions sans moteur), Dorand. Aeronautique, vol. 4, no. 32, Jan. 1922, pp. 11–16, 4 figs. Discusses and calculates behavior of machines at various wind conditions and summarizes results.

FLOW OF GASES

Cylinders. The Flow of Gas Into a Cylinder, A. Johnson. Automobile Engr., vol. 12, no. 160, Feb. 1922, pp. 4143, 7 figs Discusses flow of atmospheric air into cylinder of an internal-combustion engine, assuming that temperature of air does not alter. Works out calculations applicable to its flow.

Liquids and Gases. Determination from the Pressure Reduction in Pipes of Quantity of Gas and Liquid Flowing Therefrom (Bestimmung von strömenden Gas- und Flüssigkeitsmengen aus dem Druckabfall in Rohren), Max Jakob. Zeit. des Vereines deutscher Ingenieure, vol. 66, no. 8, Feb. 25, 1922, pp. 177–182. Simple calculation according to law of similarity of Reynolds and Blasius. The two constants of this law are newly determined by means of tests with air; tests with water show that with same constants, water quantities can be accurately calculated. Recommends use of smooth pipes instead of gasometers as standard measuring tool for nozzle calibrations.

FLUE GASES

Testing Apparatus. Apparatus for Testing Flue Gas, John B. C. Kershaw. Combustion, vol. 6, no. 3, Mar. 1922, pp. 125–128, 8 figs. Describes Duplex-Mono automatic, Foxboro-Heath CO_2, Hays automatic CO_2 and draft recorders.

The Unograph (Der "Unograph"), Kurt Müller. Archiv für Wärmewirtschaft, vol. 3, no. 2, Feb. 1922, p. 33, 1 fig. Describes apparatus for determination of carbonic acid which functions without use of absorption media.

FOREMEN

Teaching Ability, Developing. Building Up Teaching Ability in Foremen, D. J. MacDonald. Am. Mach., vol 56, nos. 10 and 11, Mar. 9 and 16, 1922, pp. 360–361 and 406 408. Explains why average foreman is not a good teacher, and points out importance of planning teaching work, and what constitutes good teaching.

Training. As Foreman Is, So Is the Plant, C. R. Hook, E. A Holbrook and Arthur Notman. Iron Trade Rev., vol. 70, no. 12, Mar. 23, 1922, pp 820–822. Deals with training of foremen. Report of subcommittee on education of Am.Inst.Min. & Met. Engrs.

Foremanship Training, E. T. Terce Indus. Management, vol 63, no. 4, Apr 1922, pp 216–217. Notes on questions to be answered. Suggested outline of preliminary course.

FOUNDRIES

Cupolas. See CUPOLAS.

Desulphurization Process. The Walther Desulphurization Process (Das Walthersche Entschwefelungsverfahren). Zeit. für die gesamte Giessereipraxis, vol. 43, no. 8, Feb. 25, 1922, pp. 101–103. Account of tests carried out with this process at the A. Borsig foundry at Berlin-Tegel, demonstrating that it is possible, with comparatively simple means and without interference with operation or workers, to successfully combat the disagreeable sulphur enrichment. Abstract of paper by H. Scharlibbe and discussion before Assn. German Foundrymen.

Railway Iron and Steel. Control in a Railway Iron and Steel Foundry, G. N. Shawcross. Foundry Trade Jl., vol. 25, no. 281, Jan. 5, 1922, pp. 3 8, 7 figs. Discusses coöperation of chemist and molder, pre-war and post-war output, air compressors, cupolas, annealing and pyrometry, etc. Read before Cambridge Univ. Eng. Soc.

Space and Equipment, Utilization of. Volumetric Efficiency as a Measure of Foundry Costs, Douglas T. Sterling. Indus. Management, vol. 63, no. 4, Apr. 1922, pp. 201–205, 3 figs. Relations between floor space, flask volume and weight of castings.

FREIGHT HANDLING

Package. Organization and Modern Handling of Package Freight through Freight Houses, G. Marks. N. E. R. R. Club, Feb. 14, 1922, pp. 278–289 and (discussion) pp. 289–314. Author outlines facts and methods, based on results of personal observation and operation, in handling large volumes of freight in all sorts of places under varying conditions.

FUELS

See OIL FUELS; PULVERIZED COAL.

FURNACES, BOILER

German Bamag. The New Bamag Furnaces for High- and Low-Grade Fuels (Die neuen Bamagfeuerungen für gute und geringe Brennstoffe), H. Pradel. Wärme- u. Kälte-Technik, vol. 24, no. 5, Mar. 1, 1922, pp. 56–59, 6 figs. Describes new nozzle grate of the Berlin-Anhalt Machine Constr. Corp., and its application to their forced-draft horizontal grates, traveling grates and underfeed furnaces.

Semi-Producer-Type. The Bergmans Semi-Producer-Type Furnace (Bergmans-Halbgasfeuerung), H. Nettmann. Zeit. des Vereines deutscher Ingenieure, vol. 66, no. 6, Feb. 11, 1922, pp. 131–132, 2 figs. Details of furnace and basic principles on which design is based. Results of tests.

FURNACES, FORGING

Types. Discussion of Forge Furnaces, Charles Longenecker. Blast Furnace & Steel Plant, vol. 10, no. 3, Mar. 1922, pp. 194–196. Discusses soaking pits, regenerative and non-regenerative types, and furnaces of small hearth area, pointing out possibilities for saving and increased efficiency with various classes of fuel.

FURNACES, HEAT-TREATING

Lead Hardening. Lead Hardening Furnaces for Heating Hammers and Hatchets, G. T. Straub. Forging & Heat Treating, vol. 8, no. 3, Mar. 1922, pp. 160–161, 1 fig. Describes hardening furnaces used in Evansville Tool Works which have proved very satisfactory.

G

GAGES

Hand- and Machine-Lapped Surfaces of Precision. Hand- and Machine-Lapped Surfaces as Seen Through a Microscope. Machy. (N. Y.), vol. 28, no. 8, Apr. 1922, pp. 638–639, 6 figs. Includes examples of photomicrographs made by Pratt & Whitney Co., Hartford, Conn., in connection with study of characteristics of different surfaces, as obtained by various methods.

Machining Dial. Tooling Equipment and Methods Used in Making Dial Gages, Robert Mawson. Machy. (N. Y.), vol. 28, no. 8, Apr. 1922, pp. 627–630, 13 figs. Describes operations performed in Stickney & Randall plant, Waltham, Mass.

GAS ENGINES

Working Fluids, Properties of. Some Properties of the Working Fluid of Gas Engines, W. T. David. Engineering, vol. 113, no. 2932, Mar. 10, 1922, pp. 281–284, 2 figs. Notes on pressures developed on explosion; after-burning in gas engines; internal energy of working fluid; factors governing heat loss during explosion-expansion stroke. Results of experiments made by author.

GASES

Discharge Through Orifices or Nozzles. The Effect of Variable Specific Heat on the Discharge of

Gases Through Orifices or Nozzles, William J. Walker. Lond., Edinburgh, & Dublin Philosophical Mag. & Jl. Sci., vol. 43, no. 255, Mar. 1922, pp. 589–593. Discusses the question whether or not it is desirable to account for abnormal orifice or nozzle discharges by consideration of changes in value of γ, index in equation pv^γ=constant, for adiabatic changes of state.

GASOLINE

Anti-Knock Compounds for Aircraft. Effect of Doped Fuels on the Fuel System. Automotive Industries, vol. 46, no. 12, Mar. 23, 1922, p. 661, 1 fig. Use of anti-knock compounds in aircraft.

GEAR CUTTING

Machines. Commercial Gear-cutting Practice, Franklin D. Jones. Machy. (N. Y.), vol. 28, no. 6, Feb. 1922, pp. 437–446, 20 figs. Cutting of spur gears on automatic machines of formed-cutter type. See also Machy. (Lond.), vol. 19, no. 495, Mar. 23, 1922, pp. 749–757, 20 figs.

Shapers. Cutting Spur Gears on Gear Shapers. Machy (N. Y.), vol. 28, no. 8, Apr. 1922, pp. 645–650, 14 figs. Use of machines operating with planing or shaping action and forming gear teeth by generating and formed-cutter processes.

GEARS

Automobile, Wear in. Wear on Various Automobile Gear Steels, E. R. Ross. Am. Mach., vol. 56, no. 14, Apr. 6, 1922, pp. 515–519, 6 figs. Results of tests showing various factors which affect wear in driving gears. A tooth-profile indicator.

Auto-Pitch. A New Form of Gear, W Rees Darling. Machy. (Lond.), vol. 19, no. 492, Mar. 2, 1922, pp. 664–667, 17 figs. Describes auto-pitch gear obtained by roller flow, resulting from studies of requirements of a perfect gear. (Abstract.) Read before Instn. Engrs. & Shipbuilders in Scotland.

Hotchkiss-Taylor Tangent. The Hotchkiss-Taylor System of Gearing. Engineering, vol. 113, no. 2935, Mar. 31, 1922, p. 401, 10 figs. partly on p. 400. Describes system in which rack is arranged in plane tangential to cylinder. Basic gear form is a crown wheel, teeth of which are involute curves in plane normal to axis of crown wheel.

Spiral Bevel. The Spiral Bevel Gear. Machy. (Lond.), vol. 19, no. 492, Mar. 2, 1922, pp. 653–654, 2 figs. Comparison between arcs of action of spiral and helical teeth and straight teeth.

Tooth-Rolling Machine. Rolling the Teeth in Hot Gear Blanks, Frederick E. Walker, Jr. Am. Mach., vol. 56, no. 11, Mar. 16, 1922, pp. 409–412, 6 figs. Process eliminates cutting gear teeth. Rolling bevel gears in 15 seconds, and saving 20 to 40 per cent of metal.

Production by Rolling Process. Production of Gears by the Rolling Process. Can. Machy., vol. 27, no. 9, Mar. 2, 1922, pp. 46–47, 7 figs. Pressure required; forming of teeth; redressing die rolls; etc.

GLUES

Water-Resistant. Water Resistant Glues: Casein and Blood Albumin, Robert Herman Bogue. Chem. Age (N. Y.), vol. 30, no. 3, Mar. 1922, pp. 103–106. Manufacture of casein by lactic acid, acid coagulation grain-curd, and other methods; influence of method of manufacture; casein glue and cements; preparation of blood albumin glue.

GOVERNORS

Steam Haulage Engines. The Governing of Steam Haulage Engines (Die Fahrtregler der Dampfördermaschinen), H. Hoffmann. Zeit. des Vereines deutscher Ingenieure, vol. 66, nos. 8, 9 and 10, Feb. 25, Mar. 4 and 11, 1922, pp. 173–177, 207–210 and 226–229, 29 figs. Uses and development of governors, and regulation of speed obtainable therewith. Astatic and static regulation. Nature and strength of static centrifugal governors; changing from one direction to the other; regulation of start. Examples of modern governors.

GRAIN ELEVATORS

Automatic Box-Car Unloader. Automatic Box-Car Unloading in Grain Elevators, C. D. Howe. Can. Ry. & Mar. World, no. 290, Apr. 1922, pp. 169–172, 6 figs. partly on p. 173. Describes automatic box-car unloader developed for use in reconstruction of Can. Nat. Rys. elevator at Port Arthur, Ont. which has storage capacity of over 8,500,000 bush. of grain.

Pneumatic. Discharge of Grain Cargoes in the Port of London by Pneumatic Elevators, R. E. Knight. Instn. Mech. Engrs. Proc., vol. 2, no. 8, Dec. 1921, pp. 917–931 and (discussion) pp. 931–969, 10 figs. Deals with pneumatic discharge of grain from ships.

GRINDING

Printing-Press Parts. Grinding Printing-Press Parts, B. K. Price. Abrasive Industry, vol. 3, no. 2, Feb. 1922, pp. 45–46, 2 figs. Cylinders and rolls are finished accurately on large grinders at plant of an eastern printing press manufacturer.

Shears. Grinding Shears in New England Plant, Herbert R. Simonds. Iron Trade Rev., vol. 70, no. 11, Mar. 16, 1922, pp. 751–756, 5 figs. Describes grinding problems involved in shear manufacture and practice at the Acme Shear Co., Bridgeport, Conn., producers of cast-steel shears and scissors complete from raw material to finished product.

GRINDING MACHINES

Centerless. Centerless Grinding Efficiency, H. J. Swanson. Abrasive Industry, vol. 3, no. 3, Mar. 1922, pp. 75–76, 1 fig. Rapid production is possible as wheel cuts continuously; results of practical tests are given and inspection methods are described.

Chilled Iron Rolls. Large Grinding Machine for Chilled Iron Rolls. Engineer, vol. 133, no. 3455, Mar. 17, 1922, p. 306, 2 figs. on p. 307. Describes heavy roll machine with capacity for work up to 36 in. diam. by 18 ft. between centers.

Oil Feed Control. Grinding Machine With Oil Feed Control. Can. Machy., vol. 27, no. 9, Mar. 2, 1922, p. 48, 2 figs. Design based upon principle of high traverse speeds.

Tool and Cutter. An Improved Tool and Cutter Grinder. Eng. Production, vol. 4, no. 75, Mar. 9, 1922, pp. 225–226, 5 figs. Details of improved pattern of universal machine by Alfred Herbert, Ltd., Coventry, one of distinctive features of which is provision made for wet grinding.

H

HAMMERS

Electric. The Electric Hammer, P. Trombetta. Am. Inst. Elec. Engrs., vol. 42, no. 4, Apr. 1922, pp. 297–305, 9 figs. Electric hammer has been studied and developed by writer to point where it seems to show superiority to present used hammers, in simplicity, safety, running expenses, cost of installation and upkeep, and in many cases in original cost. Development shown is of induction motor type.

HARDNESS

Scleroscope for Testing. Uses Scelroscope on Thin Sections, Fred S. Triton. Foundry, vol. 50, no. 6, Mar. 15, 1922, pp. 225–227, 2 figs. Samples a quarter-inch thick give accurate results when mounted by new methods. Low readings are obtained when samples are supported in ordinary ways. Paper presented before British Inst. of Metals.

HEALTH

Factory Dental Clinic. What a Dental Clinic Can Do in Your Factory, Linwood G. Grace. Factory, vol. 28, no. 4, Apr. 1922, pp. 405–407, 3 figs. Why dental clinic pays and how to operate one.

HEAT PUMPS

Evaporators and. Experiences on Evaporators with Heat Pumps (Erfahrungen an Eindampfanlagen mit Wärmepumpe), E. Wirth. Zeit. des Vereines deutscher Ingenieure, vol. 66, no. 7, Feb. 16, 1922, pp. 160–164, 13 figs. Reports on installations with evaporators for slowly boiling liquids and with vacuum evaporators for low-boiling temperatures show to what extent vapor compression has been realized after overcoming practical difficulties and as result of laboratory tests.

HEAT TRANSMISSION

Building Materials. A Study in Heat Transmission with Special Reference to Building Materials, F. C. Houghten. Am. Soc. Heating & Vent. Engrs. Jl., vol. 28, no. 2, Mar. 1922, pp. 151–172, 13 figs. Notes on theory of heat flow; methods of determining heat transmission. Discussion of research work on heat transmission through building and allied materials by various investigators. Work of research laboratory.

Conduction and Convection. Heat Transfer by Conduction and Convection, W. K. Lewis, W. H. McAdams and T. H. Frost. Am. Soc. Heating & Vent. Engrs. Jl., vol. 28, no. 2, Mar. 1922, pp. 97–106, 2 figs. Points out that mass velocity, viscosity and thermal conductivity are major factors in determining coefficient of heat transfer from gases or liquids to solids, and that, for accuracy, heat transfers must be calculated by use of film coefficients, one on each side of heating surface.

HEATING, ELECTRIC

Houses. Limits of Electric House Heating, E. A. Loew. Elec. World, vol. 79, no. 13, Apr. 1, 1922, pp. 623–625, 6 figs. Large-scale heating of residences, stores and other establishments in Tacoma shows limits within which electric heating may compete with other heat in mild climates. (Abstract.) University of Wash. Eng. Experiment Station, Bul. no. 15.

HEATING, STEAM

Central Stations. Mechanical Use of Power in Low-Pressure Steam to Improve the Position of Central Heating Stations (Utilization mécanique de l'énergie contenue dans la vapeur a très basse pression pour l'amélioration des installations de chauffage central), André Nessi. Bul. de la Société d'Encouragement pour l'Industrie Nationale, vol. 133, no. 10, Dec. 1921, pp. 1322–1366, 31 figs. Use of steam for improving circulation of hot water and hot air, for fans, pumps, etc.

HOISTS

Electric, Connections for. Hoisting-Machine Connections for Direct Current (Hebezeug-Schaltungen für Gleichstrom), L. Weiler. Siemens-Zeit., vol. 2, nos. 2 and 3, Feb. and Mar. 1922, pp. 76–81 and 108–114, 14 figs. Different types of connections by the Siemens-Schuckert Works, special connections, safety devices.

HYDRAULIC TURBINES

Efficiency Tests. Efficiency Tests of a New Turbine at the Boise Works (Note sur les essais de rendement d'une des nouvelles turbines de l'usine du Bois Noir), A. de Montmollin. Bul. Technique de la Suisse Romande, vol. 48, no. 4, Feb. 18, 1922, pp. 37–40, 2 figs. Results of tests of horizontal axis Francis turbines for Lausanne Electricity Works, showing nearly 90 per cent efficiency at full charge as against 81 per cent guaranteed.

Ejector, Moody. The Moody Ejector Turbine, S. Logan Kerr. Mech. Eng., vol. 44, no. 4, Apr. 1922, pp. 243–247, 15 figs. Particulars of a turbine for low-head installations which delivers rated horsepower at maximum efficiency when head is a maximum, and also maintains output when head is reduced at flood periods.

HYDROELECTRIC DEVELOPMENTS

Niagara Falls. Increasing Niagara Falls Power Development By 200,000 Hp., G. W. Morrison. Compressed Air Mag., vol. 27, no. 3, Mar. 1922, pp. 65–69, 12 figs. New project under construction by Niagara Falls Power Co., requiring driving of a 32-ft. tunnel, a distance of 4,500 ft.

HYDROELECTRIC PLANTS

Caribou, California. High Head Impulse Wheels at New Feather River Plant. Eng. News-Rec., vol. 88, no. 12, Mar. 23, 1922, pp. 472–477, 7 figs. Caribou hydro-electric plant in California has two 30,000-hp. impulse turbines under 1008-ft. head. Water is brought from headwater reservoir by tunnel, river and pipe. Includes article entitled General Features of Design of the Caribou Plant, by Albert A. Northrop; and article on transportation problem in plant construction.

Kern River, California. Hydroelectric Installation on the Kern River, Ely C. Hutchinson. Mech. Eng., vol. 44, no. 4, Apr. 1922, pp. 239–241, 7 figs. Two turbo-generators arranged for dual operation at either 50 or 60 cycles. Unique equipment for efficient use of water supply.

Modern Structures. The Construction of Modern Hydroelectric Plants (Die Bauausführung neuzeitlicher Wasserkraftanlagen), M. Enzweiler. Siemens-Zeit., vol. 2, no. 3, Mar. 1922, pp. 93–102, 27 figs. Deals with construction of dams, headwater canals, power stations, etc.

Sand Box. Design of Sand Box for Kern River Hydro-Electric Plant, H. L. Doolittle. Eng. News-Rec., vol. 88, no. 15, Apr. 13, 1922, pp. 616–617, 4 figs. Operation of high-head reaction turbines demands clear water. Test shows 400-ft. tank settles particles passing 200-mesh sieve.

Shawinigan Falls, Canada. Extension to Shawinigan Hydro-Electric Plant, Julian C. Smith. Can. Engr., vol. 42, no. 11, Mar. 14, 1922, pp. 299–306, 15 figs. New 41,000-hp. unit has world's largest steel casing and biggest valve ever built. Foundation slab is 12-ft. thick, 52-ft. space. Paper read before Eng. Inst. Can.

Test Code, A.S.M.E. Test Code for Hydraulic Power Plants and Their Equipment. Mech. Eng., vol. 44, no. 4, Apr. 1922, pp. 248–258, 13 figs. Preliminary draft of the sixth in series of 19 test codes being formulated by A.S.M.E. committee on power test codes.

I

ICE MANUFACTURE

Center-Freeze System. Ice Making by the Center-Freeze System, A. G. Solomon. Power Plant Eng., vol. 26, no. 5, Mar. 1, 1922, pp. 279–281. Five-ton blocks are produced in 30 hr. from raw water.

Uniflow Engines, in. Ice-Making With the Unaflow Engine, Sterling H. Bunnell. Power, vol. 55, no. 13, Mar. 28, 1922, pp. 505–506, 1 fig. Comparison of electric-motor and steam-engine operation shows greater possibilities of economy for latter.

IMPACT TESTING

Mild Steel. New Tests With Repeated Impact (Nouvelles expériences de chocs répétés), Léon Guillet. Révue de Métallurgie, vol. 18, no. 12, Dec. 1921, pp. 755–757, 1 fig. Describes experiments with various mild steel test bars, showing especially effect of cold working.

INDICATORS

Steam-Engine, Diagram. Why Complete Compression Is Not Economical. Power, vol. 55, no. 13, Mar. 28, 1922, pp. 496–499, 11 figs. Discusses compression line on indicator diagram, showing that compression to inital pressure is not efficient. Describes graphical method of finding proper compression for any given cutoff.

INDUSTRIAL MANAGEMENT

Brass and Copper Industry. Management in the Brass and Copper Industry, James E. Morrison. Management Eng., vol. 2, nos. 1, 2, 3 and 4, Jan., Feb., Mar. and Apr. 1922, pp. 3–6, 4 figs.; 103–108, 8 figs.; 173–178, 6 figs. and 237–242, 4 figs. Account of author's experience during eight years in development of management methods in some of largest brass and copper mills in United States and Canada. Jan.: Possibilities in better utilization of existing resources. Feb.: Setting and using standards of accomplishment. Mar.: Problem of brass mill standards. Apr.: Planning for production in brass mill.

Overhead Distribution. Distributing Overhead to Allow Lower Sales Prices, Walter N. Polakov. Factory, vol. 28, no. 4, Apr. 1922, pp. 400–402, 4 figs. Outlines plan for decreasing costly item of idle machines and men until business comes back.

Production Control. Watching Production from the Office, A. W. Hinkel. Factory, vol. 28, no. 4, Apr. 1922, pp. 416–418, 5 figs. Describes planning department that actually controls production and makes it possible to guarantee date of completion.

Production Costs, Cutting. Cutting Production Costs by Combining Manufacturing Operations, C. B. Bartlett. Indus. Management, vol. 63, no. 4, Apr. 1922, pp. 198–200. Account of experience of large company which found that combining manufacturing operations helped materially to eliminate wasted production time.

Production Methods. Modern Production Methods W. R. Basset. Am Mach vol 56, no. 12, Mar 23, 1922, pp. 443–445. Administrative methods Advantages of functional organization, periodical reports save conference time

Production Planning and Control. The Planning and Control of Production R O Herford Indus Administration Jl vol 1, no 9, Jan 1922 pp 259–261 (includes discussion) Discusses date maximum output from a given plant, maximum output from limited capital, maximum output at minimum cost, as factors in control of production, etc

Ratio Chart for Inventory Control The Ratio Chart Applied to Inventory Control Bert E Holmes Indus. Management vol 63, no 4 Apr 1922, pp 243–245, 1 fig. Author shows facility with which ratio chart may be used for ascertaining rapidly and accurately various factors of inventory

Routing. How to Study the Routing of Work Edward H Tingley Management Eng, vol 2 no 4, Apr. 1922, pp. 209–214 9 figs Such analysis is said to be particularly helpful in older plants and those which have expanded rapidly

Sales Records. Keeping Track of Sales and Distributors, A H. Tuechter Am Mach., vol. 56, no. 15, Apr. 13, 1922, pp 541–543, 9 figs Cards and forms for recording sales and shipping data in shop and office. Records to show activities of agents

Tool Crib Service. Stabilizing and Standardizing Tool Crib Service, James H. Delany Indus. Management, vol. 63, no. 4, Apr 1922 pp 209–216, 2 figs. How to eliminate time and tool losses

Tool-Division Organization. Organization of a Large Tool Division, H. P. Losely Machy (N Y), vol. 28, no. 8, Apr. 1922 pp 632–637, 10 figs Duties of various members and units of organization responsible for development of quantity production tools.

INDUSTRIAL ORGANIZATION

Knitting Mill. The Organization of Knitting Mills, Carle M. Bigelow. Management Eng, vol. 2, no. 4. Apr. 1922, pp. 221–226, 6 figs. Standardizing control of manufacturing.

INDUSTRIAL PLANTS

British. Famous British Works Eng Production, vol. 4, no. 75, Mar. 9, 1922, pp. 218–220, 6 figs. Layout of works of John I. Thornycroft & Co, Ltd. Basingstoke for manufacture of commercial motor vehicles, covering 18 acres.

INDUSTRIAL RELATIONS

Antagonism of Capital and Labor. The Inevitable Antagonism Between Employers and Employees. Management Eng., vol. 2, no. 4, Apr. 1922, pp 233–236. Discussion of C. E. Knoeppel's article in March issue of same journal.

INJECTORS

Principle and Application. Practical Information About Injectors, Terrell Croft. Power, vol 55, no. 12, Mar. 21, 1922, pp. 460–463, 11 figs. How different types work; advantages and disadvantages, applications; testing; selection; how to overcome operating troubles.

INTERNAL-COMBUSTION ENGINES

Castings for. Castings for Internal-Combustion Engines, Ben Shaw and James Edgar Foundry Trade Jl., vol. 25, no. 290, Mar 9, 1922, pp 174–176, 28 figs. Considers pattern-shop and foundry work of smaller castings.

Combined Compressed-Air and. Possibilities of Combined Internal-Combustion and Compressed Air Engines, R. W. Robinson. Practical Engr., vol. 65, no. 1828, Mar. 9, 1922, pp. 118–119 Describes design of prime mover which will combine outstanding advantages of steam engine with those of internal-combustion engine and, as far as possible, eliminate disadvantages of both, to produce engine of greater thermal efficiency than present internal-combustion engine From paper read before Inst. Mar Engrs.

Efficiency. Efficiency of Internal-Combustion Engines (Rendement organique des moteurs à combustion interne), André Planiol. Comptes Rendus des Séances de l'Académie des Sciences, vol. 174, no. 10, Mar. 6, 1922, pp. 663–666. Discusses losses by friction as a criterion by which to judge mechanical quality of engine and describes new method of measuring friction losses.

Elastic. Elastic Internal-Combustion Engines (Elastische Verbrennungsmotoren), Aurel Persu. Motorwagen, vol. 25, no 8, Mar 20, 1922, pp. 153–158, 8 figs. Deals with increasing limit of elasticity of engines without changing volume of cylinder that is, for ordinary engines with constant stroke.

[See also AIRPLANE ENGINES, AUTOMOBILE ENGINES, DIESEL ENGINES; GAS ENGINES, MARINE ENGINES, Still; OIL ENGINES.]

IRON AND STEEL

Packing for Export. Exporting Iron and Steel, V. G. Iden. Iron Trade Rev, vol 70, no. 12, Mar. 23, 1922, pp. 823–826, 5 figs Containers for certain classes of goods have been generally standardized for shipments intended for foreign markets. Deals with packing.

IRON CASTINGS

Gray. The Problem of Grey Iron Castings, H. J. Young. Foundry Trade Jl, vol. 24, nos. 279 and 280, Dec. 22 and 29, 1921, pp. 497–501 and 511–514, 19 figs. Composition of pig iron; possibilities of standard castings; turbine castings; duplexing; importance of graphite, test-bars, influence of phosphorus; sulphur-manganese balance versus silicon control; absence of standard composition in internal-combustion engines. Paper read before Inst Min. Engrs.

J

JIGS

Standardisation of Fixtures and. Standardization of Jig and Fixture Design Machy. (N Y.), vol. 28, no 8, Apr 1922, pp 610–613, 5 figs. Discusses use of standardized parts, such as shoulder screws fixture keys, shoulder drill bushings, binder handles, etc

L

LABORATORIES

Missouri School of Mines. Mining Laboratory of the Missouri School of Mines, C. R. Forbes. Min. & Sci. Press, vol 124, no. 11, Mar. 18, 1922, pp. 359–360, 2 figs. Describes small experimental mine for purpose of supplementing classroom study of mining operations with laboratory where practical demonstrations might be given.

LATHES

Turret. The Herbert No. 11 Bar Turret Lathe. Machy. (Lond.), vol. 19, no. 491, Feb. 23, 1922, pp. 637–638, 3 figs. Describes lathe by Alfred Herbert, Ltd., Coventry, in which possibilities of danger, damage and wear have been reduced to a minimum.

LIGHTING

Committee Report. Illumination Items. Am. Inst. Elec. Engrs. Jl., vol. 41, no. 4, Apr. 1922, pp. 278–280, 3 figs. Report of Lighting and Illumination Committee on highway lighting, textile-mill lighting standards, elixit devices, and color temperature and its relation to quality of light.

Industrial Plants, Code for. Tentative Lighting Code. Textile World, vol. 41, no. 13, Apr. 1, 1922, pp. 79, 115 and 117. Rules and regulations made by Mass. Dept. of Labor and Industries for lighting industrial establishments.

LIQUID-MEASURING DEVICES

Tests. Testing of Liquid-Measuring Devices, Ralph W. Smith. U. S. Bur. of Standards, Weights and Measures, Miscellaneous Publications no. 48, 1922, pp. 64–72. Necessity for accuracy of mechanically operated liquid-measuring devices, and possibility of fraudulent use.

LOCOMOTIVE BOILERS

Seams, Calculating Efficiency of. Calculating the Efficiency of Boiler Seams, R. J. Finch. Ry. Mech. Engr., vol. 96, no. 4, Apr. 1922, pp. 193–196, 5 figs. Explains use of two tables which facilitate work and reduce chance for error; places where failure is likely to occur.

Tubes. Installing and Maintaining Charcoal Iron Locomotive Boiler Tubes, G. H. Woodroffe and C. E. Lester. Boiler Maker, vol. 22, no. 3, Mar. 1922, pp. 61–65, 20 figs. Makes recommendations regarding application of body tubes, superheater flues, and arch tubes. See also Ry. Mech. Engr., vol. 96, no. 4, Apr. 1922, pp. 221–225, 20 figs.

Welding. Expert Report on Locomotive Boiler Welding—Details of Approved Methods of Selecting Material and Perfecting Repairs. Ry. & Locomotive Eng., vol. 35, no. 3, Mar. 1922, pp. 62–64, 19 figs.

LOCOMOTIVES

British and American Design. British and American Locomotive Design and Practice, P. C. Dewhurst. Engineering, vol. 113, nos. 2934 and 2935, Mar. 24 and 31, 1922, pp. 373–377 and 405–408, 11 figs Some comparative comments thereon from practical experience. Paper read before British Instn. Mech. Engrs.

British Works. The Works of the South Eastern and Chatham Rly. Co. Eng. Production, vol. 4, nos. 77 and 78, Mar. 23 and 30, 1922, pp. 271–275 and 298–302, 21 figs. Description of organization and shop practice in locomotive and car works.

Cab Signals. On the Question of Locomotive Cab Signals (France), Jules Verdeyen. Inst. Ry. Assn. Bul., vol. 4, no. 3, Mar. 1922, pp. 537–552, 8 figs. Report on repeating and recording track signals on locomotive; different systems already used or tried, results obtained; recording running speed of locomotives.

Counterbalancing Reciprocating Masses. The Development of Counterbalancing in British Locomotive Practice, F. W. Brewer. Engineer, vol. 133, no. 3455, Mar. 17, 1922, pp. 298 and 300. History of development down to present-day practice.

Diesel-Engined. Possibilities of the Diesel Locomotive. Ry. Mech. Engr., vol. 96, no. 3, Mar. 1922, pp. 120–121. Editorial note. Disadvantages of Diesel engine for locomotive service.

Electric. See ELECTRIC LOCOMOTIVES.

Electric Camshaft Control. The English Electric Camshaft Control. English Elec. Jl., vol. 2, no. 1, Jan. 1922, pp. 27–35, 12 figs. Describes master controller for heavy locomotives and multiple-unit stock, designed to give reliability with lowest possible maintenance cost.

4-8-2 and 2-10-2 Types. New Mountain Type and Santa Fe Type Locomotives for the Manila Railroad. Ry. & Locomotive Eng., vol. 35, no. 3, Mar. 1922, pp. 65–66, 2 figs. Describes 4-8-2 type, with tractive effort of 28,600 lb., for passenger service, and 2-10-2 type, with tractive effort of 35,700 lb., for freight service.

Handling on Descending Grades. Handling Locomotives on Descending Grades, A. G. Newell. Ry. Mech Engr, vol 96, no 3, Mar 1922, pp 132–135, 6 figs Drifting and by-pass valves important; effect of reverse lever position and use of throttle.

New Russian 0 10 0 Type. Construction, Manufacture and Transport of the Locomotives for Russia Ordered From Nydqvist and Holm A. B. (Konstruktion, tillverkning och transport av de hos Nydqvist & Holm a.-b. beställda ryska lokomotiven), Bengt Sjölin Teknisk Tidskrift (Utgiven av svenska teknologföreningen), vol. 52, no 8, Feb. 25, 1922, pp 119–131, 12 figs. Reviews development of Trollhättan work shops and describes new Russian 0 10 0-type locomotive building.

Tire-Roughing Mill. Tire-Roughing Mill Engineering, vol. 113, no. 2931, Mar. 21, 1922, pp. 351–356, 4 figs. Describes powerful tire roughing mill, which is capable of rough-rolling from slabbed blanks, ready for finishing mill, locomotive tires of largest diameter and can also produce broad rings up to 12 in. in width.

Trailer Wheels. Rolled Steel Trailer Wheels for Locomotives. Ry. Mech. Engr., vol. 96, no. 4, Apr. 1922, pp. 189–190, 3 figs. Also Ry. Age, Mar. 11, 1922, pp. 571–572, 3 figs. Method of manufacture of Edgewater Steel Co.

Valve Gear. Walschaert Valve Gear Variable Lead. Ry. Mech. Engr., vol. 96, no. 4, Apr. 1922, pp. 187–188, 4 figs. Modifications discusses secure ample lead while running combined with no lead when starting.

LUBRICANTS

Paraffin Series. Boundary Lubrication—The Paraffin Series, W. B. Hardy and Ida Doubleday. Royal Soc. Proc., vol. 100, no. A 707, Mar. 1, 1922, pp. 550–574, 5 figs. Results of experiments, and theory. Lubricating qualities of normal paraffins and their related acids and alcohols; influence of quantity of lubricant; solid lubricants; influence of chemical constitution.

Testing Apparatus. A Proposed Method for Solving Some Problems in Lubrication, William Stone. Commonwealth Engr., vol. 9, nos. 4 and 5, Nov. 1 and Dec. 1, 1921, pp. 115–122 and 139–149, 13 figs. Describes method of testing and construction of apparatus employed to determine conditions of formation and stability of lubricating film and effect of variations of viscosity in different parts of film due to varying temperatures. Results of tests carried out.

Viscosity and Friction. Viscosity and Friction, Winslow H. Herschel. Sci. Lubrication, vol. 2, no. 1, Jan. 1922, pp. 10–21, 2 figs. Viscosity effect in complete-film-lubrication regeme; viscosity estimation at one temperature from observed viscosity at another temperature; friction testing of bearing metals; transition point; oiliness of different lubricants; service tests; desirable features of oil-friction testing machines. Paper read before S.A.E.

LUBRICATING OILS

Automotive-Engine, Dilution of. The Dilution of Lubricating Oil in the Present Automotive Engine, William F. Parish. Sci. Lubrication, vol. 2, no. 1, Jan. 1922, pp. 5–7 and 21. Dilution through decomposition of oil; leakages of raw gasoline; leakages during compression stroke; extent to which dilution exists; results of dilution; wear; etc. Paper read before combined meeting of Am. Petroleum Inst., Soc. Automotive Engrs., and Nat. Automobile Chamber of Commerce.

Compounding. Compounding of Lubricating Oils, W. F. Osborne. Power, vol. 55, no. 14, Apr. 4, 1922, pp. 535–536. Points out that for steam-engine cylinders and marine-engine lubrication compounding is essential. On the other hand, a pure mineral oil should be used where there is any danger of water causing emulsion.

Emulsions. The Cause of Emulsions in Lubricating Oils, W. F. Osborne. Power, vol. 55, no. 13, Mar. 28, 1922, pp. 502–503. Notes on separation of water and oil; impurities in oil; effect of compounding.

Pour Test. The Meaning of Cloud and Pour Points in Lubricating Oil, W. F. Osborne. Power, vol. 55, no. 12, Mar. 21, 1922, pp. 458–459, 2 figs. Describes method of making pour test.

Steam Cylinders. Compounded Cylinder Oil for Superheated Steam Conditions. Lubrication, vol. 8, no. 1, Jan. 1922, p. 9. Recommends use of medium-heavy viscosity cylinder oil, having about 4 or 5 per cent of animal oil.

Steam-Turbine. Keeping Steam Turbine Lubricating Oil in Good Condition, Charles H. Bromley. Sci. Lubrication, vol. 1, no. 12, Dec. 1921, pp. 5–11, 7 figs. Lubrication trend in turbine practice; turbine-oil circulating systems; formation of emulsion and sludge; acidity; continuous by-pass system; requirements of efficient oil filter for purifying steam turbine oil; etc. Reprinted from Gen. Elec. Rev.

Substitutes. Lubricants and Their Substitutes (Ueber Schmiermittel und deren Ersatzstoffe), Bruno Simmersbach. Wärme- u. Kälte-Technik, vol. 24, no. 5, Mar. 1, 1922, pp. 53–56. Experience in Germany with substitute oils.

LUBRICATION

Lubricants and. Lubrication and Lubricants. Sibley Jl. of Eng., vol. 36, no. 2, Feb. 1922, pp. 18–29 and 37, 7 figs. Discusses loss of friction, viscosity of lubricants, laws of lubrication, etc.

Theory. Theory of Lubrication, William F. Parish. Sci. Lubrication, vol. 1, no. 11, Nov. 1921, pp. 15–19. Discusses the two functions of a lubricant, keeping

surfaces apart, and conveying heat from surfaces that is caused by friction.

M

MACHINE SHOPS

High-Speed Production. Examples of Modern High Speed Production, H. A Wilson. Can. Machy., vol. 27, no. 7, Feb. 16, 1922, pp. 27–30, 11 figs. Methods adopted at Ford motor plant.

Modern Design. An Eastern Shop of Modern Design, C. E. Clewell. Am. Mach., vol. 56, nos. 14 and 56, Apr. 6 and 13, 1922, pp. 508-511 and 558-559, 7 figs. Machine-tool plant of Gould & Eberhard, Irvington, N. J., has saw-tooth roof and reinforced-concrete frame. Mercury-vapor lamps for shop. Railroad and power facilities. Crane service and sanitary arrangements.

MACHINE TOOLS

Bearings, Adjustments of. The Adjustment of Machine Tool Bearings, Fred Horner. Machinery (Lond.), vol. 19, no. 482 and 483, Dec. 22 and 29, 1921, pp. 342–347, 385–387, 53 figs. Discusses divided, solid, and tapered bearings, and gives a number of examples of their adjustments; contraction of parallel bushings; capped bearings; end adjustments.

Economical. Economical Machine Tools (Wirtschaftliche Werkzeugmaschinen), H. Vossmann. Betrieb, vol. 4, no. 11, Mar. 4, 1922, pp. 345–349, 8 figs. Main features of a single-disc high-speed lathe and a new turret lathe. Results of tests on a four-spindle automatic machine. Relations between cutting speed and width of cutting and between efficiency and sharpness of tools. A logarithmic alignment chart is presented, with help of which, number of pieces machined per hr. on automatic machines, and working time for given length on lathes can be determined.

Progress. Machine Tool Progress. Engineering, vol. 113, no. 2933, Mar. 17, 1922, pp. 424–426, 9 figs. Describes machining methods and appliances developed in recent years at works of Alfred Herbert, Ltd., Coventry, England.

MALLEABLE IRON

Manufacture. Progress in Manufacture of Malleable Iron, Enrique Touxeda. Can. Foundryman, vol. 13, no. 3, Mar. 1922, pp. 32–34. Air-furnace thermal efficiency; proportioning air supply; use of waste-heat boilers; design of double-hearth furnace; use of coke-oven gas; etc.

MARINE ENGINES

Still. The Still Engine for Marine Propulsion, Archibald Rennie. Engineering, vol. 113, nos. 2931 and 2932, Mar. 3, and 10, 1922, pp. 275–278, 14 figs. partly on supp. plate and pp. 309–312, 8 figs. Also Mar. Engr. & Naval Architect, Mar. 1922, pp. 107–110, 4 figs. (Abstract.) Discusses engine of single-piston type which works on its combustion (or top) side upon two-stroke port scavenging principle, and employs airless (solid) injection for fuel oil; on its steam (or bottom) side it operates upon single-acting principle.

MEASURING INSTRUMENTS

Accuracy. The Accuracy of Measuring Instruments (Genauigkeiten der Messzeuge), R. P. Schröder. Betrieb, vol. 4, no. 9, Feb. 11, 1922, pp. 269–274. Notes on gage blocks, initial comparative, trial and working gages. Measurement of workpieces.

Optical Equipment. Optical Auxiliary Equipment for Measuring Instruments (Optische Hilfsmittel an Messgeräten), Walter Block. Betrieb, vol. 4, no. 9, Feb. 11, 1922, pp. 285–289, 6 figs. Discusses optical media for measuring instruments of all kinds, but especially those used in machine construction, for purpose of manipulating them with greater ease and accuracy.

METALS

Grain Growth and Recrystallization. Grain Growth and Recrystallization in Metals, Zay Jeffries and R. S. Archer. Chem. & Met Eng., vol. 26, nos. 8, 9 and 10, Feb. 22, Mar. 1 and 8, 1922, pp. 343–345, 402–410 and 449-457, 39 figs. Feb. 22: Technical definition of recrystallization, and list of recrystallization temperatures for common metals. Methods for measuring grain size, shape and volume. Mar. 1: Effect of time and temperature of heating, degree of cold-work, original grain size and obstructing impurities on grain growth of metals and solid solution alloys. Mar. 8: Possible causes of grain growth; recrystallization is grain growth of fragmented crystals; germination; formation of nuclei.

Mechanical Properties of. Variation of Mechanical Properties in Metals and Alloys at Low Temperatures (Sur la variation des propriétés mécaniques des métaux et alliages aux basses températures), Léon Guillet and Jean Cournot. Comptes Rendus des Séances de l'Académie des Sciences, vol. 174, no. 6, Feb. 6, 1922, pp. 381-386. Experiments with a number of metals; table of Brinell hardness and resiliency of these at +20 deg., —20 deg., —80 deg. and liquid air temperatures.

Strength and Fatigue. Calculation of a Non-Circular Cylindrical Envelope (Méthode générale de calcul des enveloppes cylindriques a section non circulaire), P. Cayere. Houille Blanche, vol. 20, no. 59-60, Nov.-Dec. 1921, pp. 213-216, 5 figs. Discusses interior pressure, fatigue of metals, etc.

Tensile Strength of Plastic. Tensile Strength (Verfestigung und Zugfestigkeit), Friedrich Körber. Stahl u. Eisen, vol. 42, no. 10, Mar. 9, 1922, pp. 365–370, 8 figs. The mechanics of tensile test of plastic metals. Notes on calculation of tensile strength from curve of true stresses. Theory that slip and rotation of crystal elements takes place is confirmed.

METEOROLOGY

Wind, Velocity of. Variation of Velocity of Wind With Altitude (La variation de la vitesse du vent avec l'altitude), Ch. Maurain. Révue Générale des Sciences, vol. 33, no. 3, Feb. 15, 1922, pp. 76–80, 5 figs. Discusses results obtained by means of recording balloons and gives comparative curves.

MICROMETERS

Lever Gages and. Accuracy Requirements of Micrometers and Lever Gages (Genauigkeitsansprüche an Mikrometer und Fühlhebel), G. Berndt. Betrieb, vol. 4, no. 9, Feb. 11, 1922, pp. 280–284. Relation between measuring and reading accuracy of screw micrometers. Suggestions for increasing accuracy of lever gages.

MILLING MACHINES

Universal. Economical Use of High-Power Universal Milling Machines (Wirtschaftliche Verwendung von Hochleistungs-Universal-Fräsmaschine), H. Pohlmann. Betrieb, vol. 4, no. 11, Mar. 4, 1922, pp. 360–363, 9 figs. Describes machine constructed by Mammutwerke, Nuremberg, Germany.

Vertical. The "Relmil" Vertical Milling Attachment. Machinery (Lond.), vol. 19, no. 493, Mar. 9, 1922, p. 699, 2 figs. Distinguishing feature is that it does not clamp or fix on lathe saddle. Is secured to back of lathe bed and also to chip tray by means of two substantial cast-iron brackets.

MOLDING

Plastic and Powdered Substances. Moulding Plastic and Powdered Substances (including Casting Substances other than Metals and Presses, Mechanical). Abridgments of Specifications, class 87(ii), 1922, 379 pp. Patents for inventions for period 1909–15.

MOLDING METHODS

Boxes. A New System in Molding-Boxes. Mech. World, vol. 71, no. 1835, Mar. 3, 1922, p. 161. Describes box having separate ends and sides, secured by a pin and two wedges, of opposed bevel, at each joint. System has proved very satisfactory in sizes from 16 in. sq. to 80 in. sq. Translated from Giesserei-Zeitung.

MONEL METAL

Water Works, Suitability for. Monel Metal and Its Suitability for Water-Works Use, H. S. Arnold. N. E. Water Works Assn. Jl., vol. 36, no. 1, Mar. 1922, pp. 86–93 and (discussion) pp. 93–94. Describes source of supply and method of manufacture. Physical properties and uses.

MOTOR-TRUCK TRANSPORTATION

Graphical Control. A Graphical Control of Motor Truck Transportation, Howell B. May. Factory, vol. 28, no. 4, Apr. 1922, pp. 410–412, 3 figs. Describes graphical planning and recording system which it is claimed, makes it possible to realize greatest number of productive minutes out of total 480 that truck is out of garage.

MOTOR TRUCKS

German Types. Motor Trucks with Special Regard to Types Exhibited at the German Automobile Show (Der Lastkraftwagen und seine vielseitige Verwendung unter besonderer Berücksichtigung der auf der D.A.A. ausgestellt gewesenen Bauarten), Karl Redtmann. Fördertechnik u. Frachtverkehr, vol. 15, nos. 1 and 2, Jan. 6 and 20, 1922, pp. 8–13 and 27–33, 39 figs. Details of various German types.

Tipping Gear. Gravity-Type Tipping Gear for Motor Wagons. Engineering, vol. 113, no. 2934, Mar. 24, 1922, p. 358, 3 figs. With described gear center of gravity of load during tipping operation moves along a straight line, with slight downward slope towards rear end of wagon.

O

OIL ENGINES

Combustion. Combustion Process in Oil Engines (Der Verbrennungsvorgang im Oelmotor), Constantin Redzich. Wärme- u. Kälte-Technik, vol. 24, no. 2, Jan. 15, 1922, pp. 17–18. Review and discussion of scientific investigations.

Doxford. Doxford's Engine and Boiler-Oil, J. L. Chaloner. Motorship, vol. 7, no. 3, Mar. 1922, pp. 187-188. Improvements made in Doxford engine and economics effected by use of boiler-oil.

Fishing Boats. Engines for Fishing Boats (Les moteurs des bateaux de pêche), Edmond Marcotte. Technique Moderne, vol 13, nos. 11 and 12, Nov. and Dec. 1921, pp. 449-457 and 518-521, and vol. 14, no. 1, Jan. 1922, pp. 21-26, 33 figs. Nov.: Discusses those of French manufacture, including kerosene and semi-Diesel engines; their operation and control. Dec.: The Tuxham-Delaunay-Belleville engine, and the Atlas Semi-Diesel. Jan.: The Bellenger and Renault Semi-Diesels, and the Chaleassière Diesel engines.

Hot-Bulb Marine. New Hot-Bulb Marine Engines of the German General Electric Co. (Neue AEG-Glühkopf-Schiffsmotoren). Motor u. Auto (formerly Oel- u. Gasmaschine and Kraftwagen), vol. 19, no. 3, Feb. 15, 1922, pp. 33-36, 2 figs. Development and present status of construction.

OIL FUELS

Boilers for. Liquid Fuel For Steam Boilers (L'Emploi des combustibles liquides pour le chauffage des foyers industriels et particulièrement des chaudières à vapeur), Louis Cauchois. Bul. des Associations Françaises de Propriétaires d'Appareils à Vapeur, no. 2, Oct. 1920, pp. 37–68, 6 figs. Properties of combustible liquids and precautions necessary in handling, including petroleum and its derivations, shale oil, alcohol, etc. Burners of various types.

Heavy, in Carburetor. The Use of Heavy Oil Fuels in Carburetors (Zur Frage der Verwendung schwerer Brennstoffe in der Vergasermaschine), J. Plünzke. Motorwagen, vol. 25, no. 7, Mar. 10, 1922, pp. 125–127, 5 figs. Determination of boiling curve for two fuels, naphthalene and anthracene, during suction and compression.

Injection and Combustion. Injection and Combustion of Fuel-Oil—VII, C. J. Hawkes. Motorship, vol. 7, no. 3, Mar. 1922, pp. 195–196, 1 fig. Experiments with solid-injection and air-blast in marine Diesel engines. (Continuation of serial.)

Internal-Combustion-Engine. Internal-Combustion Engine Fuels, C. A. Norman. Soc. Automotive Engrs. Jl., vol. 10, no. 3, Mar. 1922, pp. 187–192 and (discussion) 192 and 203. Discusses use of kerosene and gasoline, and substitute fuels, including shale oils.

Steam Power. Fuel Oil For Steam Power, A. D. White. Combustion, vol. 6, no. 4, Apr. 1922, pp. 175–176, 1 fig. Advantages of fuel oil over coal; conditions for efficiency; controlling steam supply; preheating of oil.

OPEN-HEARTH FURNACES

Design. Design of Open-Hearth Furnaces, A. D. Williams. Iron Age, vol. 109, nos. 13 and 17, Mar. 16 and 30, 1922, pp. 717–719, 1 fig. and 853–855, 2 figs. Mar. 16: Regenerator computations for volume and weight of checker work required. Temperature changes based on time reversals. Mar. 30: Regenerator and flue calculations for frictional resistance to passage of air and gases. Summation of losses.

Fluorspar, Use of. Fluorspar in Open-Hearth Practice. Iron Age, vol. 109, no. 11, Mar. 23, 1922, pp. 783–784. Effective agent in removing sulphur from steel. Action on slag and furnace lining. Old ideas altered. Translated from article by S. Schleicher in Stahl u. Eisen, Mar. 17, 1921.

German. Arrangement of Open Hearths in Germany, Hubert Hermanns. Blast Furnace & Steel Plant, vol. 10, no. 3, Mar. 1922, pp. 192–194, 3 figs. Steelmakers of Germany have not adopted water-cooled parts, but use detachable posts; arrangement of gas and air chambers is of special interest.

OXY-ACETYLENE CUTTING

Cast Iron. Cutting Cast Iron With the Oxyacetylene Torch, Alfred S. Kinsey. Stevens Indicator, vol. 38, no. 4, Oct. 1921, pp. 287–296, 5 figs. Reviews progress made with oxyacetylene torch; how to cut cast iron; effects of oxyacetylene cutting on cast iron advantages; theory of cutting of metals by gas.

OXY-ACETYLENE WELDING

Cutting and. Modern Iron Welding and Cutting Devices with Dissolved Acetylene and Oxygen (Neuzeitliche Eisen-Schweiss- und -Schneideinrichtungen mit gelöstem Azetylen und Sauerstoff), H. Kropf. Metall-Technik, vol. 48, no. 1, Jan. 1, 1922, pp. 3–4. Describes installations for workshops which are entirely fire- and explosion-proof, and can be used for various welding and cutting operations with great amount of economy and efficiency.

Instruction Sheet. Proposals for New Factory Instruction Sheets (Entwürfe neuer Betriebsblätter), Betrieb, vol. 3, no. 11, Mar. 4, 1922, pp. 39–40. Proposal of Works Dept of German Federation of Technical and Scientific Societies for care and manipulation of gas-welding equipment.

Rods for. Choosing Rods for Welding Work, J. R. Dawson. Iron Trade Rev., vol. 70, no. 15, Apr. 13, 1922, pp. 1033–1036 and 1043, 10 figs. Selection of welding rod for oxy-acetylene process depends on service requirements of finished weld. Inspection of rods and tests of welds aid in determining choice of materials. (Abstract.) Paper delivered before Int. Acetylene Assn.

Safety in. Safety Engineering as Applied to Oxy-Acetylene Cutting and Welding Apparatus, F. J. Napolitan. Am. Welding Soc. Jl., vol. 1, no. 2, Feb. 1922, pp. 13-30, 3 figs. Writer emphasizes safety of modern acetylene generators. Discusses acetylene and its generation; explosive mixtures; portable acetylene cylinders and oxygen cylinders; high-pressure gages; torches and tips; flashbacks; etc.

P

PAPER MANUFACTURE

Tar Paper. Tar Paper (Le carton bitumé), J. Tricard. Arts et Métiers, vol. 74, no. 10, July 1921, pp. 216–218, 7 figs. Discusses manufacture which has been developed during war, to supply quick and cheap protection in inclement weather.

PARACHUTES

Calthrop "H" Type. The Calthrop "H" Type Parachute and Frontal Suspension Harness. Flight, vol. 14, no. 12, Mar. 23, 1922, pp. 170–177, 5 figs. Describes latest model, "Guardian Angel" and its method of operation.

PLANERS

Open-Side. A Large Open-side Planing Machine, C. S. Pettit. Machinery (Lond.), vol. 19, no. 493,

Mar 9, 1922, pp. 689–690, 1 fig. Describes machine in which peak load is of negative character, produced by use of fly-wheels in special positions which absorb reversal effort and actually take load off motor for the time being.

PLASTIC MATERIALS

Plastic Wood. Plastic Wood. Engineer, vol. 133, no 3453, Mar. 3, 1922, pp. 230–231. Describes material like soft wood, but without grain having cellulose nitrate as a base, chief raw material being cotton. It has consistency of dough used in pastry making and can be molded into any conceivable form, it can be used for patching up patterns and rounding off fillets and in molding process for making small articles. Process of manufacture.

PLATES

Steel, Manufacture and Properties of. Manufacture and Properties of Steel Plates Containing Zirconium and Other Elements, George K. Burgess and Raymond W. Woodward. U. S. Bur. of Standards Technologic Papers, no. 207, Feb. 2, 1922, pp. 123–176, 16 figs. Describes manufacture and certain physical properties obtained from steel plates produced from about 193 heats of steel containing in various combinations following principal variable elements. Carbon, silicon, nickel, aluminum, titanium, zirconium, cerium, boron, copper, cobalt, uranium, molybdenum, chromium and tungsten.

POWER PLANTS

British Practice. Notes on British Power Plant Practice, C. H. S. Tupholme. Power Plant Eng., vol. 26, no. 6, Mar. 15, 1922, pp. 315–319. Efforts directed by engineers toward securing higher fuel economy, due to continued high prices of fuel.

Design. Developments in Power Station Design. Engineer, vol. 133, no. 3455, Mar. 17, 1922, pp. 290–292, 10 figs. partly on p. 302. Describes cooling towers of Powell Duffryn Steam Coal Co. built by Davenport Engineering Co., each designed to reduce temperature of 216,000 gal. of water per hr. from 100 deg. Fahr. under average atmospheric conditions, turbine-driven feed pump; coal and ash-handling plant, etc.

Rubber-Tire Factory. A Modern Power Plant in the Rubber-Tire Industry. Power, vol. 55, no. 12, Mar. 21, 1922, pp. 448–454, 15 figs. Details of coal-handling equipment, water-tube boilers, superheaters, steam turbines, air compressors and hydraulic pumps of the Cumberland (Md.) Plant of Kelly-Springfield Tire Co.

POWER TRANSMISSION

Oil Variable Gear. Power Transmission by Oil (Elaulic Gear), H. S. Hele-Shaw. Instn. Mech. Engrs. Proc., no. 7, 1921, pp. 843–873, 16 figs. Author discusses power transmission when it is accompanied with its transformation, and where oil is employed as working agent. Design and applications of oil variable gear, or elaulic gear.

PRESSES

Forging, Steam-Hydraulic. Steam-Hydraulic Forging Presses (Les presses vapo-hydrauliques a forger). Outillage. vol. 249, no. 9, Mar. 4, 1922, pp. 271–273, 6 figs. Describes hydraulic presses in which high-water pressure is produced by steam compressor.

Safety Devices. Making a Punch Press Department Safe, C. B. Auel. Am. Mach., vol. 56, no. 14, Apr. 6, 1922, pp. 501–503, 9 figs. How manufacturing company has greatly reduced accidents. Methods and devices that helped make for safety.

PRESSURE VESSELS

Mechanically Welded. The Strength of Mechanically Welded Pressure Containers, R. J. Roark. Mech. Eng., vol. 44, no. 4, Apr. 1922, pp. 225–230, 18 figs. Describes pressure tests made on electrically welded, gas-welded, and riveted pressure containers, and tension and shear tests made on specimens of welded metal, carried out for purpose of demonstrating strength and uniformity of construction in which electric weld is employed.

PRESSWORK

Tools for Aluminum Ware. Press Tools for Aluminum Ware, Frank A. Stanley. Am. Mach., vol. 56, no. 12, Mar. 23, 1922, pp. 437–438, 5 figs. Press tools for blanking, bending and perforating; how body is drawn; spouts attached by use of welding torch.

PRODUCER GAS

Cleaning Without Washing. Cleaning Producer Gas Without Washing, James H. Matheson. Iron Age, vol. 109, no. 14, Apr. 6, 1922, pp. 916–917, 4 figs. Gas equalizer and soot collector developed to treat gas from bituminous coal.

Furnace Work, Producer Gas for Furnace Work. Engineering, vol. 113, no. 2934, Mar. 24, 1922, pp. 347–351, 34 figs. partly on supp. plate. Describes low-temperature rotary carbonization plant devised by Harold Nielsen, consisting essentially of combination of ordinary producer with low-temperature carbonizing retort, in which partial distillation of raw coal is effected by sensible heat of producer gas. Designed to improve efficiency of manufacture of producer gas, and permit recovery of valuable by-products.

PULVERIZED COAL

Systems of Burning. Burning Pulverized Fuel—V, F. P. Coffin. Combustion, vol. 6, no. 4, Apr. 1922, pp. 181–184, 2 figs. Discusses conditions of efficient combustion, tube slag, effect of furnace temperature on ash, baffling of horizontal water-tube boilers, and describes some recent installations. Excerpts from author's contribution on "The Utilization of Coal on a Multiple-Product Basis" to Bacon and Hamor's "American Fuels."

PUMPING PLANTS

Diesel-Driven. Diesel-Driven Pumping Plant for Trinidad. Engineer, vol. 133, no. 3453, Mar. 3, 1922, p. 248, 3 figs. partly on p. 242. Describes treble-ram pump for Trinidad, with capacity of 76,000 gal. per hr. when running at 44 r.p.m. and with head of 350 ft. Pump is driven by means of 200-hp. Diesel engine of four-cylinder, four-cycle pattern.

PUMPS

High-Lift Turbine. High Lift Turbine Pumps A. M. Attack. So African Instn. Engrs. Jl., vol. 20, no. 7, Feb. 1922, pp. 130–145 and (discussion) 145–146, 19 figs. Discusses some of the more important features upon which a successful design will depend, including multi-stage and centrifugal pumps, pumps in series, axial thrust, pumps driven by synchronous motors, sinking pumps, impellers, diffuser, etc.

Jets, Impact Losses of. Impact Losses of Jets, J. B. Burnell. Engineering, vol. 113, no. 2935, Mar. 31, 1922, pp. 404–405, 4 figs. Account of experiments made by author to determine loss of kinetic energy in jet due to varying deviation, and friction losses in bends. (Abstract.) Paper read before Melbourne Division of Instn. Engrs., Australia.

Pipe Efficiency. Pipe Friction and Pump Efficiency, William Brasenall. Colliery Guardian, vol. 123, no 3191, Feb. 24, 1922, pp. 472–473. Results of experiments carried out with turbine, three-throw ram, and differential ram pumps. (Abstract.) Paper read before Min. Inst. of Scotland.

PUMPS, CENTRIFUGAL

Types and Operation. Centrifugal Pumps, J. W. Rogers. Eng. Rev., vol. 35, nos. 8 and 9, Feb. and Mar. 1922, pp. 259–262 and 296–301, 12 figs. Feb.: Advantages, principles, operating characteristics, efficiency and regulation, power requirement, electric motors. Mar.: Describes some modern types.

PYROMETERS

Ardometer and Holborn-Kurlbaum. The Measurement of High Temperatures with the Ardometer and the Holborn-Kurlbaum Pyrometer (Die Messung hoher Temperaturen mit Ardometer und Holborn-Kurlbaum-Pyrometer), Georg Keinath. Metall-Technik, vol. 47, no. 20, Dec. 15, 1921, pp. 161–164 and vol. 48, no. 1, Jan. 1, 1922, pp. 1–3, 9 figs. Describes the Holborn-Kurlbaum optical pyrometer, and the ardometer which is based on the Féry total-radiation pyrometer and said to possess excellent resistive qualities and great reliability.

R

RAILS

Head, Conditions Affecting. Conditions Affecting the Head of a Rail, James E. Howard. Eng. & Contracting, vol. 57, no. 11, Mar. 15, 1922, pp. 252–253. Review of destructive influences. Paper presented before N. Y. R. R. Club.

RAILWAY CONSTRUCTION

Specifications. American Railway Engineering Convention. Eng. News-Rec., vol. 88, no. 12, Mar. 23, 1922, pp. 498–501, 1 fig. Rail committee presents experimental rail specification based on quiet -seeting steel. Engineers and labor economics. Analysis of warehouse and freighthouse design. Specifications for movable bridges adopted.

RAILWAY ELECTRIFICATION

Economies Due to. The Future of Railroading is Electrification, W. R. Steinmetz. Can. Ry. Club Official Proc., vol. 20, no. 8, Nov. 8, 1921, pp. 16–39 (includes discussion). Discusses electrification generally in various countries, and enumerates economies due to it.

Holland. Electrification of Railways in Holland (Electrificatie van de spoorwegen in Nederland), J. J. W. Van Loenen Martinet. Ingenieur, vol. 37, no. 9, Mar. 4, 1922, pp. 151–162, 8 figs. Discusses report of commission appointed to study the question, which is review of electrification practice in various countries; also Amsterdam-Rotterdam electrification.

Induction Interference and Electrolysis. Effects of Electric Power Used for Traction, Chas. F. Scott. Ry. Age, vol. 72, no. 11, Mar. 18, 1922, pp. 727–729, 1 fig. Inductive interference and electrolysis as related to railroad electrification.

Superpower Survey. Superpower Survey, Gen. Elec. Rev., vol. 25, no. 2, Feb. 1922, pp. 72–91, 15 figs. Articles on The Superpower System as an Answer to a National Power Policy, by W. S. Murray; What the Superpower Survey Means to the United States, by H. Goodwin, Jr.; and Abstract of "Appendix C" of Superpower Report on the Electrification of Railroads, by W. D. Bearce.

RAILWAY MOTOR CARS

Gasoline. Gasoline Motor Cars for Railways (Motor-Benzol-Triebwagen für Eisenbahnen). Verkehrstechnik, vol. 39, no. 11, Mar. 17, 1922, pp. 130–131, 1 fig. Describes new cars with four-cycle engine built by the Kiel Dockyards of the German Works Corp., with 2 or 4 axles, weighing 9 and 15 tons, and having accommodation for 42 and 95 passengers, respectively.

Gasoline Motor Cars with Four-Wheel Drive. Ry. Age, vol. 72, no. 11, Mar. 18, 1922, 749–750, 4 figs. For passenger, freight and light switching; manufactured by Four-Wheel Drive Auto Co., Clintonville, Wis.; has three speeds; four-cylinder engine; 42 hp. by S.A.E. rules, but develops 68 hp. on a brake test.

New Haven Branch Lines. Motor Cars Used on New Haven Branch Lines. Ry. Mech. Engr., vol. 96, no. 3, Mar. 1922, pp. 139–141, 3 figs. Describes the Mack rail car used in local passenger service. Important advantages are flexibility and low-operating cost.

RAILWAY OPERATION

Automatic Train Control. American Train Control System. Ry. Signal Engr., vol. 15, no. 3, Mar. 1922, pp. 101–104, 6 figs. Detailed description of intermittent contact or ramp type system, developed by Am. Train Control Co. On right side of track ramps are arranged to apply brakes, on left side ramps are arranged to give only cautionary indication in cab.

Automatic Train Control System of General Railway Signal Co. Ry. Rev., vol. 70, no. 10, Mar. 11, 1922, pp. 330–337, 11 figs. Describes operation and advantages claimed.

G. R. S. Company's Auto-Manual Train Control. Ry. Elec. Engr., vol. 13, no. 3, Mar. 1922, pp. 95–97, 6 figs. Recent improvements by General Ry. Signal Co. of Rochester, in their automatic train-control system. Essential element of this system is arrangement for permitting engineman to cut out automatic brake-setting machinery and keep in his own hands full control of train; hence the name auto-manual train control.

Recent Tests of Train Stops and Control. Ry. Elec. Engr., vol. 13, no. 2, Feb. 1922, pp. 67–70, 5 figs. Describes Webb automatic train stop, and the M-V. All Weather train control, and tests carried out with them.

The Bourdette-Brookins Train Control System. Ry. Rev., vol. 70, no. 10, Mar. 11, 1922, pp. 353–355, 7 figs. System featuring three-position mechanically held plunger, to provide clear, caution and stop indications.

The Hearing on Train Control. Ry. Rev., vol. 70, nos. 12 and 13, Mar. 25 and Apr. 1, 1922, pp. 421–424 and 455–460. Gives summary of argument of 40 American railroads represented by Am. Ry. Assn. against recent order of Interstate Commerce Commission requiring installation of automatic train control.

The Regan Automatic Train Control Systems. Ry. Rev., vol. 70, no. 10, Mar. 11, 1922, pp. 337–344 9 figs. Intermittent contact type, consisting of two elements, one comprising locomotive and tender equipment and other, apparatus located on roadside. See also Ry. Signal Engr., vol. 15, no. 3, Mar. 1922, pp. 116–120, 8 figs.

The Simplex Train Control System. Ry. Rev., vol. 70, no. 10, Mar. 11, 1922, pp. 351–353, 3 figs. Works on principle of telegraphing track conditions to engine which is automatically controlled by device that applies air brakes.

The Union Switch & Signal Company's Automatic Train Control System. Ry. Rev., vol. 70, no. 10, Mar. 11, 1922, pp. 348–350, 6 figs. Describes company's complete speed-control system used as automatic-stop system.

Motive-Power Maintenance. Notes on the Maintenance and Supply of Motive Power in a Railway District, W. Land and H. B. Buckle. Ry. Gaz., vol. 36, nos. 2, 3, 4, 5 and 6, Jan. 13, 20, 27, Feb. 3 and 10, 1922, pp. 54–56, 97–100, 133–137, 170–173 and 212–215, 25 figs. Discusses maintenance and supply of power and its utilization as two interdependent questions which must be considered concurrently, and their supervision should be under one responsible command. Jan. 13: Running repairs; cleaning of engines. Jan. 20: Washing out of boilers; tube sweeping. Jan. 27: Sheer legs; electric wheel drops. Feb. 3: Preparing engine for work; mechanical handling of firebox ashes, method of dealing with engines in locomotive yard; breakdowns. Feb. 10: Distribution of locomotives for passenger and freight train arrangements in a given district.

Tonnage Rating. Practical Points on Dynamometer Car Tonnage Tests, O. O. Carr. Ry. Rev., vol. 70, no. 13, Apr. 1, 1922, pp. 451–455. Observations on Illinois Central show inaccuracy of office ratings and false economy of reducing tonnage to increase train speed.

RAILWAY SHOPS

Welding Practice. Standards of Railroad Shop Welding Practice, G. M. Calmbach. Ry. Elec. Engr., vol. 13, no. 2, Feb. 1922, pp. 51–56, 18 figs. Typical examples of boiler welding practice and general rules.

RAILWAY SIGNALING

Audible Signal. The Federal Signal Company's Audible Signal. Ry. Elec. Engr., vol. 13, no. 3, Mar. 1922, pp. 97–98, 1 fig. Describes experiments on Boston & Albany in Massachusetts and New York.

Missouri, Kansas & Texas Installations. The M. K. & T. Signaling Program. Ry. Signal Engr., vol. 15, no. 3, Mar. 1922, pp. 93–95, 10 figs. Describes installation with new ideas in pole-line construction, trunking and battery housing, of Missouri Kansas & Texas.

RAILWAY TIES

Life. A Means of Determining the Average Life of Ties, V. K. Hendricks. Ry. Age, vol. 72, no. 12, Mar. 25, 1922, pp. 779–783, 2 figs. Explanation of fluctuations in requirements on new lines and method of anticipating them.

Renewal Cost Calculation. Diagram for Calculating Annual Cost of Cross Ties, E. R. Cary. Eng. & Contracting, vol. 57, no. 11, Mar. 15, 1922, pp. 245–246, 2 figs. Describes method of making nomograph or alignment diagram.

RAILWAY TRACK

Curves. Railway Curves: Superelevation and Main-

tenance, E. E. R. Tratman. Eng. News-Rec., vol. 88, nos. 11 and 12, Mar. 16 and 23, 1922, pp. 446-449 and 489-492, 2 figs. Shows variations in practice and opinion. Influence of modern locomotives; relations of curvature to gage and grades; checking and marking.

RAILWAYS

Alaska. Completing the Government Railroad in Alaska. Ry. Age, vol. 72, no. 13, April 1, 1922, pp. 813–817, 8 figs. Describes Alaska railroad opened between Seward, on Resurrection Bay, and Fairbanks, in interior, on Feb. 5, 1922, a distance of 467 miles.

REFRIGERATING MACHINES

Compression. The Compression Refrigerating Machine, Gardner T. Voorhees. Ice & Refrigeration, vol. 62, no. 3, Mar. 1922, pp. 223–226, 1 fig. Study of floating heat question and clearance effect. (Continuation of serial.)

REFRIGERATION

Brine Spray. Brine Spray Refrigeration, S. C. Bloom. A.S.R.E. Jl., vol. 8, no. 4, Jan. 1922, pp. 308–321 (includes discussion) 10 figs. Describes experiments carried out with Webster nozzles and overhead spray systems.

RESEARCH

Industrial. A Plan for the Development of Industrial Research in Canada, S. F. Ruttan. Honorary Advisory Council for Sci. & Indus. Research, Dominion of Can., Bul. no. 10, 1921, 8 pp. (Abstract.) Address before Chem. Congress, New York.

RIVETS

Manufacture and Types. Riveting (Etude sur le rivetage). Ouvrier Moderne, vol. 4, no. 11, Feb. 1922, pp. 443–447, 12 figs. Metal used; manufacture of rivets; standard types of rivets; etc.

ROLLING MILLS

Drives. Factors which Influence the Size of Rolling-Mill Drives, L. Rothera. Iron & Coal Trades Rev., vol. 104, no. 2818, Mar. 3, 1922, pp. 306–308, 8 figs. Choice of sections to be rolled; output required; methods of rolling; drafting of rolls; number of passes taken. From English Elec. Jl.

Equipment. Adds New Rolling-Mill Equipment, Joseph Horton. Iron Trade Rev., vol. 70, no. 11, Mar. 16, 1922, pp. 746–748, 4 figs. Modern machinery installed in plants of Wm. Beardmore & Co., Ltd., Glasgow, Scotland, in transforming plant from war to peace-time production.

Friction Drive. A Friction Drive for Rolling Mills. Engineering, vol. 133, no. 3453, Mar. 3, 1922, p. 247, 3 figs. Describes new patented form of driving arrangement making use of friction rollers instead of ordinary gearing between engine and mill.

Sheet-Steel Rolling. The Possibility of Improved Methods of Rolling Sheet Steel, Sumner B. Ely. Blast Furnace & Steel Plant, vol. 10, no. 3, Mar. 1922, pp. 175–178. Author does not think that a continuous sheet mill is impossible; believes extensive scientific experiments on the problem should be conducted. (Abstract.) Paper read before Engrs.' Soc. Western, Pa.

ROPE DRIVE

Continuous and Multiple Systems. Power Transmission by Ropes. Eng. & Indus. Management, vol. 7, no. 10, Mar. 23, 1922, pp. 287–289, 3 figs. Questions of cost and efficiency construction of rope pulley drives; relative merits of continuous and multiple systems.

S

SAFETY

Organization in Industrial Plant. Safety Organization, Harry A. Schultz. Safety, vol. 9, no. 3, Mar. 1922, pp. 56–74, 8 figs. Discusses in detail safety organization of an industrial plant, duties of safety committees and safety engineers, educational activities, first aid and rescue, etc.

SAND, MOLDING

Handling Equipment. Solving Sand Problem in a Steel Foundry, Edwin F. Cone. Iron Age, vol. 109, no. 15, Apr. 13, 1922, pp. 985–988, 6 figs. Mechanical equipment shakes out castings and prepares old and new sand with minimum of labor. Other features.

Uses and Abuses. Uses and Abuses of Molding Sands, Eugene W. Smith. Iron Age, vol. 109, no. 13, Mar. 30, 1922, pp. 860–861. Typical American sands and their composition; sand for various metals. Discussion. Paper read before Chicago Foundrymen's Club.

SCHOOLS, TECHNICAL

Ottawa. Wide Range of Instruction is Being Given, W. W. Nichol. Can. Machy., vol. 27, no. 11, Mar. 16, 1922, pp. 48–49, 4; figs. Activities of Ottawa Technical School, and its equipment. Subjects cover machine-shop practice, automobile mechanics, welding and cutting, structural and mechanical drafting, etc.

Toronto. This School Shows Remarkable Progress. Can. Machy., vol. 27, no. 11, Mar. 16, 1922, pp. 35–39, 8 figs. Describes the Technical High School, Toronto, and its facilities and equipment.

SCIENTIFIC MANAGEMENT

See INDUSTRIAL MANAGEMENT.

SCREW MACHINES

Automatic. 2-In. Automatic Screw Machine. Engineering, vol. 113, no. 2932, Mar. 10, 1922, pp. 286–290, 12 figs. Details of machine constructed by Brown & Sharpe Mfg. Co., Providence, L. I. Largest size stock it will work is $2^3/_8$ in. in diam., turning any up to 5 in. and feeding any length up to 6 in. It turns out from 3 to 180 pieces per hr.

Set-Up Instructions for Automatic. Set-Up Instructions for Brown & Sharpe Automatics, Samuel R. Gerber. Machy. (N. Y.), vol. 28, no. 8, Apr. 1922, p. 607. Gives list of setting-up operations for automatic screw machines and detailed explanation of operations.

SCREW THREADS

Comparator. Screw-Thread Measuring Comparators (Gewinde-Messkomparator), C. Büttner. Betrieb, vol. 4, no. 9, Feb. 11, 1922, pp. 289–292, 11 figs. Describes construction and function of a new optical screw-thread measuring machine for maximum accuracy, with which all dimensions can be determined in coefficients of measure.

Cutting Tools. Influence of the Automotive Industry on Thread-Cutting Tools, C. N. Kirkpatrick and G. G. Vink. Am. Mach., vol. 56, no. 13, Mar. 30, 1922, pp. 479–481, 5 figs. Development of interchangeability in automobile industry. Changes in methods of manufacturing threading tools. Design of Landis die head.

SEAPLANES

Lift and Drag. Full Scale Determination of the Lift and Drag of a Seaplane, Max M. Munk. Nat. Advisory Committee for Aeronautics Technical Notes, no. 92, Apr. 1922, 5 pp., 1 fig. Speed, barometric pressure, and number of revolutions of engine were measured, including tests with stopped engine. Results of gliding tests are used for computation of lift and drag coefficients, and by making use of them, results of engine flights are used for computation of propeller efficiency.

SHAFTS

Torsional Vibration. Torsional Vibrations in Shafts and the Nazzaro Damper (Le vibrazioni torsionali negli alberi delle distribuzioni e lo smorzatore "Nazzaro"), Pasquale Borracci. Industria, vol. 36, no. 2, Jan. 31, 1922, pp. 26–28, 5 figs. Explains origin of torsional vibrations and describes the Nazzaro device for controlling them.

SHERARDIZING

Experiments. Experiments With Sherardizing, Leon McCulloch. Metal Industry (N. Y.), vol. 20, no. 3, Mar. 1922, pp. 97–98. Formation of coating, with special reference to amount and effect of iron in coating.

SLOTTING MACHINES

Production Work on. Production Work on Slotting Machines. Machy. (Lond.), vol. 19, no. 492, Mar. 2, 1922, pp. 657–659, 6 figs. Operations advantageously performed on slotting machines or shapers of vertical type.

SMOKE ABATEMENT

Problems. The Smoke Problem, O. P. Hood. U. S. Bur. of Mines Reports of Investigations, serial no. 2323, Feb. 1922, 5 pp. Brief summary of problems. Smoke problem in England, and list of publications of Bur. of Mines dealing with problem.

SOOT BLOWERS

Steam Saving with. Steam Saving with Soot Blowers, Robert June. Textile World, vol. 41, no. 13, Apr. 1, 1922, pp. 75–76, 4 figs. Charts showing economy of improved equipment and extent of loss from excessive blowing.

SPECIFIC HEAT

Air, Steam and CO_2. The Specific Heats of Air, Steam and Carbon Dioxide, W. D. Womersley. Roy. Soc. Proc., vol. 100, no. A 706, Feb. 1, 1922, pp. 483–498, 10 figs. Describes experiments with improved Hopkinson calorimeter and gives results of hydrogen-air and carbon-monoxide experiments.

STACKS

Venturi. Venturi Stacks, A. W. H. Griepe. Combustion, vol. 6, no. 4, Apr. 1922, pp. 166–175, 18 figs. Describes Venturi-Evase-Prat-Stacks and their functioning, advantages and disadvantages, and compares different systems.

STANDARDIZATION

Norway. Standardization in Norway (Standardiseringsspörsmaalet i Norge). Teknisk Ukeblad, vol. 69, no. 8, Feb. 24, 1922, pp. 69–73. Report of committee to Norwegian Society of Industrials giving review of standardization work in countries abroad.

Progress. Progress in Engineering Standardization, C. W. Ham. Am. Mach., vol. 56, no. 13, Mar. 30, 1922, pp. 465–466. Advantages of simplified designs and adoption of uniform methods. Shop operation simplified, number of jigs reduced, stocking of parts in large quantities becomes possible. Work of American Engineering Standards Committee in establishing national and international standards.

Society Automotive Engrs. Work of. S.A.E.'s Recent Standardization Work. Automotive Industries, vol. 46, no. 14, Apr. 6, 1922, pp. 768–770, 2 figs. Revision in ball-bearing standards; Bessemer steel and wire spring stock; distributor, magneto and bumper mountings; motor-boat controls; passenger-car frames.

STEAM ENGINES

Back Pressure, Reducing. Using Exhaust Velocity To Reduce Back Pressure in Steam Engine. Power, vol. 55, no. 14, Apr. 4, 1922, p. 542, 3 figs. Prof. Stumpf and his associates, in designing a uniflow locomotive, have been able, by modification of exhaust ports and piping, to reduce back pressure on cylinder.

STEAM GENERATORS

Efficient. Modern Steam Generators for the Efficient Utilisation of Gaseous Fuels and the Efficient Recovery of Waste Heat, P. St. G. Kirke. West of Scotland Iron & Steel Inst. Jl., vol. 29, Part 3, Dec., Session 1921–1922, pp. 28–34 and (discussion) 34–36, 9 figs. on supp. plates. Discusses boiler development, including the Hopwood, Spencer-Hopwood, Bonecourt, Kirke and other types.

STEAM POWER PLANTS

Fuel Conservation. Fuel Conservation in Industrial Power Plants, David Moffat Myers. Gen. Elec. Rev., vol. 25, no. 2, Feb. 1922, pp. 95–98. Effecting economies in steam plants by proper equipment of recording instruments selected to suit local conditions.

Heat Balance and Steam Distribution. Heat Balance and Steam Distribution in a Large Service Plant, S. D. Kutner. Power, vol. 55, no. 13, Mar. 28, 1922, pp. 488–491, 1 fig. Tells how steam, hot water and power are charged to different departments in large building supplied from an isolated power plant.

STEAM TURBINES

Modern Installation. A Modern Steam-Turbine Installation in Spitzbergen (Eine moderne Dampfturbinen-Anlage auf Spitzbergen), A. C. Gogstad. Schweizerische Bauzeitung, vol. 79, no. 12, Mar. 25, 1922, pp. 149–151, 4 figs. Describes central station and equipment delivered by Oerlikon Machine Works, Switzerland.

STEEL

Alloy. See ALLOY STEELS.

Chrome. See CHROME STEEL.

Stainless, Cutlery of. Making Stainless Steel Cutlery, R. G. Hall. Iron Trade Rev., vol. 70, no. 13, Mar. 30, 1922, pp. 896–897. Carbon content of 0.30 to 0.45 per cent and chromium 13 to 15 per cent is recommended. Roll scale must be eliminated and working tools kept sharp to prevent cause for oxidation. Stainless tests. See also (abstract) in Iron Age, vol. 109, no. 13, Mar. 30, 1922, pp. 855–856.

Structural. See STRUCTURAL STEEL.

STEEL CASTINGS

Economical Production. Steel Casting Plant Has Liaison Service, G. P. Blackiston. Iron Age, vol. 109, no. 14, Apr. 6, 1922, pp. 925–927, 5 figs. How Detroit Steel Casting Co. coöperates with its customers in designing parts for effective production and decrease of waste.

STEEL, HEAT TREATMENT OF

Structural Parts. Heat Treating Steel For Structural Parts, Horace C. Knerr. Blast Furnace & Steel Plant, vol. 10, no. 3, Mar. 1922, pp. 178–183, 10 figs. Means of estimating carbon content from microstructure after annealing; comparison of effects of heat treatment on various steels from mild to tool steel.

Principles. Theory of the Heat Treatment of Steel, Walter M. Mitchell. Forging & Heat Treating, vol. 8, nos. 1, 2 and 3, Jan., Feb. and Mar. 1922, pp. 52–56, 114–118 and 162–166, 20 figs. Jan.: Critical temperatures; constitution of slowly cooling steel. Feb.: Constituents of suddenly cooled steels; practice in heat treatment. Mar.: Discusses hardening and tempering and deduces schedule of heat treatment.

STEEL MANUFACTURE

Basset Process. Steel Direct from Ore by Basset Process, Fritz Wuest. Iron Age, vol. 109, no. 15, Apr. 13, 1922, pp. 989–991, 2 figs. Its chief features and advantages. Critical discussion of claims for French process by German engineer. Cost of plant. Translated from Stahl u. Eisen, Dec. 22, 1921.

High-Speed and Tungsten. Notes on the Manufacture of High-Speed and Tungsten Steels, J. W. Weitzenkorn. Chem. & Met. Eng., vol. 26, no. 11, Mar. 15, 1922, pp. 504–508, 14 figs. Steps taken in studying segregation in high-speed and tungsten steel. Structural disposition of carbides after various heat treatments, with or without previous mechanical work.

Losses, Reducing. Reducing Losses in Steelmaking, F. G. Cutler. Iron Trade Rev., vol. 70, no. 15, Apr. 13, 1922, pp. 1040–1042, 2 figs. Method of comparing total combustion efficiency of iron and steel plant from time to time is proposed. Economic use of blast-furnace and coke-oven gas. (Abstract.) Paper to be presented before Am.Soc.Mech.Engrs.

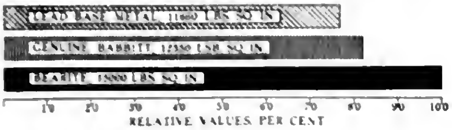
STEEL WORKS

Calcutta, India. New Plant of the Indian Iron and Steel Company, Limited. Iron & Coal Trades Rev., vol. 104, no. 2815, Feb. 10, 1922, p. 198, 3 figs. Describes design and equipment.

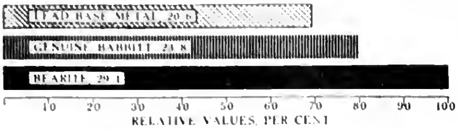
Electric Power in. The Application of Electric Power in the Iron and Steel Industry, W. S. Hall. Iron & Steel Elec. Engrs. Assn., vol. 4, no. 3, Mar. 1922, pp. 127–140 and (discussion) pp. 140–151. Brief analysis of sources of waste fuel in iron and steel manufacture; determining whether expenditure for recovering waste fuel is desirable. Problems of power generation and transmission.

Power-Plant Management. Steel Works Power Plant Management, Robert June. Blast Furnace & Steel Plant, vol. 10, no. 3, Mar. 1922, pp. 197–201, 3 figs. Fixed charges and maintenance; manner of figuring depreciation of power-house equipment.

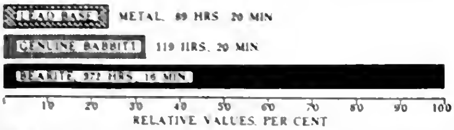
THE RELATIVE PHYSICAL PROPERTIES OF BEARITE, GENUINE BABBITT AND TYPICAL LEAD BASE METAL



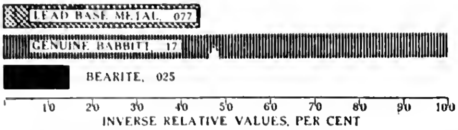
COMPRESSIVE STRENGTH: showing pressure required to reduce the test pieces 1 per cent of their original height.



BRINELL HARDNESS: indicating, not only the hardness, but the relative tenacity of the metals.



RELATIVE LIFE: the average time required to remove 1 gram of metal, with water lubrication, under varying loads and speeds.



COEFFICIENT OF FRICTION: showing the average coefficient, with water lubrication, under varying loads and speeds.

A Chart that Made History

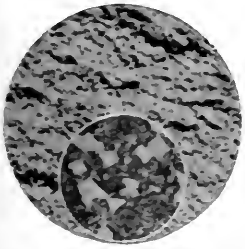
The engineer who fails to keep abreast of modern bearing practice is neglecting a factor vital to the efficient operation of his machinery.

Since 1839, the year in which Isaac Babbitt patented his famous formula, tin, copper, antimony and lead have been the foundation of all standard bearing metals. The one outstanding development since that time is the process of alloying these elements invented by the late A. W. Cadman. Did you know this?

The chart above shows the remarkable improvement in all the physical properties of babbitt made possible by this process with negligible increase in first cost.

Cadman metals, ACORN, tin-base, and BEARITE, lead-base, are guaranteed to double the life of a bearing. They cannot cut or score the shaft. They are literally the accepted standards of the world.

Engineering Bulletin M-1 is the Bearing Metal Handbook for 1922.



TYPICAL LEAD BASE METAL

Larger photo actual size, note the coarse structure. Insert is same metal magnified 100 diameters. Note the crystals which cause wear and indicate structural weakness. The analysis of this metal is identical with that of BEARITE.

CADMAN BEARITE

Note the fine, close grain in the full size photo and the elimination of the crystals in the microphoto. The unique life of BEARITE is due to the perfect alloying thus indicated.

STOKERS

Underfeed. A New Type of Underfeed Stoker. Steam, vol. 29, no. 3, Mar. 1922, pp. 75–77, 7 figs. Describes stoker built by Detroit Stoker Co., Detroit, Mich., made in two designs, one a single retort, side cleaning stoker, for boilers up to three or four hundred horsepower, and the other a multiple retort end cleaning type for large installations.

STREET RAILWAYS

Car Truck. The Brill 79-E Single Truck. Tramway & Ry. World, vol. 51, no. 13, Mar. 16, 1922, pp. 126–127, 2 figs. Has wheels of 24 to 26 in. in diameter in place of 30 to 33 in., as in 21-E single truck.

Cars, Safety. Recent Developments in Car Design, H. H. Adams. Elec. Ry. Jl., vol. 59, no. 12, Mar. 25, 1922, pp. 520–522, 7 figs. Describes automatic treadle-operated exit door of new double-door Chicago safety car. (Abstract.) Paper read before Ill. Elec. Rys. Assn.

Shallow-Conduit Construction. Installing Shallow-Conduit Construction in Washington, D. E. Dunn. Elec. Ry. Jl., vol. 59, no. 11, Mar. 18, 1922, pp. 449–452, 14 figs. Describes replacing old type of deep tube cable construction with new shallow tubes by Capital Traction Co.

Toronto. Toronto Takes Over Street Railways. Elec. Ry. Jl., vol. 59, no. 12, Mar. 25, 1922, pp. 505–511, 12 figs. Principal features of franchise; statistics of Toronto traffic; municipal operating organization; financial arrangement, etc.

STRUCTURAL STEEL

Compression Members. The Measurement of Compression Members (Ueber die Bemessung von Druckstäben), H. Bohny. Bauingenieur, vol. 3, no. 5, Mar. 15, 1922, pp. 135–141, 10 figs. Discusses results of tests carried out in Material-Testing Bureau, Berlin-Lichterfelde (see same jl., no. 1, 1922, p. 8 and Zentralblatt der Bauverwaltung, no. 5, 1922, p. 26), and compares them with other experimental results.

SUGAR

Hawaiian Islands. Experimental Work in the Hawaiian Islands. Int. Sugar Jl., vol. 24, no. 278, Feb. 1922, pp. 66–69. Annual Report of Experiment Station on superintensive cultivation, improvement of cane by bud-selection, soil investigations, and forestry work.

Manufacturing Machinery, Hawaii. Progress in Hawaii in the Design of Sugar Manufacturing Machinery. Int. Sugar Jl., vol. 24, no. 278, Feb. 1922, pp. 81–85, 7 figs. Summary of report of Committee on Manufacturing Machinery, appointed by Hawaiian Sugar Planters' Assn. Juice heaters; Kopke clarifier; Daniels' centrifugal discharge; revolving cane cutting knives.

SUPERPOWER PLANT

Advantages and Prospects. The Superpower System, Henry Flood, Jr. Steam, vol. 29, no. 2, Feb. 1922, pp. 37–40. Summarizes advantages of superpower and immediate outlook for its realization.

SWAGING

Hot. Hot Swaging. Machy. (Lond.), vol. 19, no. 494, Mar. 16, 1922, pp. 717–722, 10 figs. Discusses difference in operation of cold and hot swaging, arrangements for heating work, work-holding devices, and gives examples.

T

TERMINALS, RAILWAY

Passenger. On the Question of Terminal Stations for Passengers (all countries, except those using English language), Louis Maccallini. Int. Ry. Assn. Bul., vol. 4, no. 3, Mar. 1922, pp. 553–573, 7 figs. Report on arrangements for reducing number of movements of locomotives and empty rolling stock at passenger terminal stations.

TESTING MACHINES

Bearings. Testing Machine to Show Relative Merits of Bearings, R. W. Sellow. Belting, vol. 20, no. 3, Mar. 1922, pp. 51–53, 4 figs. Describes machine which shows relative difference in power consumption of various types of bearings; by its method of driving bearing shafts and of applying load to bearings it is adaptable to any reasonable conditions of test.

Hardness. A New Impact Hardness Testing Machine (Schlaghärteprufer nach Prof. Rich. Baumann, Stuttgart). Allgemeine Automobil-Zeitung, vol. 22, no. 43, Oct. 22, 1921, pp. 31–32, 5 figs. Describes new apparatus designed by Richard Baumann, head of material-testing bureau of Technical Academy, Stuttgart. Its cost is said to be about one-fifth that of Brinell testing machine, it is light in weight and easily handled.

TEXTILE INDUSTRY

Cotton Printing. Colors and Process of Printing Cloth (Matières colorantes et procédés d'impression dans l'Industrie des toiles imprimées), Georges Lanorville. Nature, no 2497, Feb. 11, 1922, pp. 81–84, 3 figs. Colors used for cotton prints and processes of impressing and fixing them on fibre.

TEXTILE MACHINERY

Embroidering Machines. Automatic Embroidering Machines, Oskar Spohr. Eng. Progress, vol. 3, no. 3, Mar. 1922, pp. 55–59, 16 figs. Automatic machines controlling mechanical motion of needle and shifting frame for material in accordance with predetermined pattern. Pattern card and Jacquard arrangement.

[See also COTTON GINS.]

TEXTILE MILLS

See COTTON MILLS.

THERMOCOUPLES

Platinum : Platinum-Rhodium. Life Tests of Platinum : Platinum-Rhodium Thermocouples, C. O. Fairchild and H. M. Schmitt. Metal Industry (Lond.), vol. 20, no. 11, Mar. 17, 1922, pp. 245–246. Discusses deterioration at high temperatures, requiring frequent replacement or recalibration. Published by permission of Bur. of Standards.

TIME STUDY

Motion Study and. Time and Motion Study, Eric Farmer. Eng. & Indus. Management, vol. 7, no. 9, Mar. 9, 1922, pp. 247–250 and 251, 4 figs. Examples of motion study. Experiment in sweet dipping.

TOOLS

Machinists', Manufacture of. Machinists' Tools and Their Manufacture. Engineering, vol. 113, no. 2932, Mar. 10, 1922, pp. 290–292, 7 figs. Particulars of tools and manufacturing methods adopted for their production in works of C. A. Vandervell & Co., Ltd., London. Deals with production of calipers and dividers, vee blocks and clamps, scribing blocks, etc.

TRACTORS

Chain-Track. The New Transport. Motor Transport, vol. 34, no. 890, Mar. 29, 1922, pp. 341–345, 12 figs. Describes chain-track tractors which embodies principles introduced into 25-mile-an-hour tanks that appeared after war.

Farm. The Hermite Single-Wheel Tractor (Tracteur Monoroue, Système L'Hermite), E. Weiss. Génie Civil, vol. 80, no. 6, Feb. 11, 1922, pp. 133–134, 4 figs. Describes agricultural tractor whose single driving wheel can be turned in its place and whose engine has no valves.

Standards in Manufacture. The Value of Standards in Tractor Manufacture, P. M. Heldt. Soc. Automotive Engrs. Jl., vol. 10, no. 4, Apr. 1922, pp. 270–272. Outlines history of systematic introduction of standards in mechanical manufacture. Discusses steel and other standards, such as tractor hitches, belt speeds, connections between parts or machines made in different plants, screw sizes, lug attachment, etc.

Two-Wheeled, Stability of. Stability of Two-Wheeled Tractors, P. M. Heldt. Automotive Industries, vol. 46, no. 11, Mar. 16, 1922, pp. 614–616, 4 figs. Principles and calculation of torque, pressure, drawbar-pull, etc.

TUBES

Billet-Piercing Machine for Making. An Improved Billet Piercing Machine for Solid Drawn Tube Making. Metal Industry (Lond.), vol. 20, no. 11, Mar. 17, 1922, p. 255, 1 fig. Describes machine made by Fisher, Humphries & Co., for piercing copper billets as well as steel billets.

Seamless. The Manufacture of Seamless Tubing, Philip Davidson. Raw Material, vol. 5, no. 2, Mar. 1922, pp. 46–52, 27 figs. Describes operations at Scoville Mfg. Co.'s works, Waterbury, Conn.

TUBING

Seamless Steel. Experiments With Weldless Steel Tubing As Used in Construction, W. W. Hackett. Practical Engr., vol. 65, nos. 1820 and 1821, Jan. 12 and 19, 1922, pp. 21–22 and 43–44, 4 figs. Short review of seamless tubes; describes tests made on front forks, plain tubes held in a loose socket, and on tubes brazed 1 in. into thick lugs results of alternating stress tests, showing effects of cut, with sharp corners, in high and medium-carbon steels. (Abstract.) Paper read before Instn. Automobile Engrs.

V

VALVES

Automatic Control. Automatic Control Valve for Hydraulic Presses. Engineer, vol. 133, no. 3455, Mar. 17, 1922, p. 308, 10 figs. Describes Barton-Carr patented control valve which is entirely automatic in its action from first operation onward until point of maximum high pressure is reached.

Manganese Bronze for Stems. Manganese Bronze for Valve Stems, William R. Conard. N. E. Water Works Assn. Jl., vol. 36, no. 1, Mar. 1922, pp. 32–36 and (discussion) pp. 37–39. Deals with valves as used for water-works purposes.

VENTILATION

Electric. Electric Ventilating, Wm. T. Reace and Geo. C. Breidert. Elec. Jl., vol. 19, no. 3, Mar. 1922, pp. 119–123, 8 figs. Use in the home, retail stores, industrial plants, restaurants, and for farmers. Right and wrong way to install ventilating fans. Unit heaters.

Temperature, Humidity and Air-Motion Effects. Temperature, Humidity and Air Motion Effects in Ventilation, O. W. Armspach and Margaret Ingels. Am. Soc. Heating & Vent. Engrs. Jl., vol. 28, no. 2, Mar. 1922, pp. 173–190, 17 figs. Consideration of fundamental laws underlying loss of heat from human body and resulting feelings of comfort or discomfort in air under various conditions of temperature, humidity and rate of air movement.

VOCATIONAL TRAINING

Blind. Blind Efficiently Operate Machine Tools, Hubert Hermanns. Iron Age, vol. 109, no. 11, Mar. 16, 1922, p. 733, 5 figs. Siemens-Schuckert Works in Berlin conduct series of experiments to determine proper training methods.

W

WAGES

Incentive System. Incentives and Rate-Setting Applied to the Smaller Plant and Varied Product, E. Wadsworth Stone. Management Eng., vol. 2, no. 4, Apr. 1922, pp. 205–208. Points out that incentives of fixed or predetermined nature will of themselves fail of their full power to obtain desired results if they do not parallel and include good will and hearty coöperation of workmen and management.

Outlines Incentive Wage System, William P. Butler. Abrasive Industry, vol. 3, no. 2, Feb. 1922, pp. 39–41, 2 figs. Discusses essential conditions to make incentive system successful.

Piecework Payment. Interpreting Average Hourly Earnings on Semiautomatic Operations, Paul Faltin and Leon Blog. Management Eng., vol. 2, no. 4. Apr. 1922, pp. 215–219, 1 fig. Method outlined applies to piecework system of wage payment.

WASTE ELIMINATION

Economic Fundamentals. Elimination of Waste and Improvement of Efficiency. What are the Economic Fundamentals? W. R. Ingalls. Min. & Metallurgy, no. 183, Mar. 1922, pp. 33–37. Writer points out that miscalculations in industry will decrease along with increase in transparency in industry, meaning acquisition of knowledge about it and thereby ability to see through it and ahead.

Factories. Searching Out the Invisible Wastes, C. J. Morrison. Indus. Management, vol. 63, no. 4, Apr. 1922, pp. 196–197. Calls attention to persistent and prevalent sources of loss found in every factory, which can generally be eliminated.

WATER POWER

Mechanical Storage. The Mechanical Storage of Water Power. Elec. Rev. (Lond.), vol. 90, no. 2311, Mar. 10, 1922, pp. 327–330, 9 figs. Describes Walkeburn hydroelectric scheme. Low-pressure turbines consist of two large double-runner, horizontal Francis turbines, 110 hp. each, running at speed of 200 r.p.m.; the Pelton wheel runs at 1,000 r.p.m. and is coupled direct to 155-kw. generator; arrangement of generator pumps and gearing.

Mechanical Storage of Water Power as a Factor in Textile Production. Electrician, vol. 88, no. 2284, Feb. 24, 1922, pp. 229–233, 6 figs. Describes hydroelectric installation at Henry Ballantyne & Sons' Tweedvale and Tweedholm mills, special feature of which is method adopted for water storage during non-working hours.

Resources, Canada. Water Power Resources of Canada, J. T. Johnston. Can. Engr., vol. 42, no. 13, Mar. 28, 1922, pp. 343–346. Review of hydroelectric development; power utilized in central station and pulp and paper industries. Many water powers not yet developed.

United States. Developed and Potential Water Powers of the United States. Elec. World, vol. 79, no. 11, Mar. 18, 1922, pp. 531–532, 1 fig. Government compilation indicates that capacity of waterwheels installed in plants of 100 hp. or more is 7,852,948 hp. Almost 80 per cent in public-utility generating plants.

WEIGHING

Substitution. Weighing by Substitution, C. A. Briggs and E. D. Gordon. U. S. Bur. of Standards Technologic Papers, no. 208, Feb. 21, 1922, pp. 177–192, 3 figs. Describes plan for making substitution weighings, applicable either to equal-arm balances or compound-lever scales, that has been developed in connection with standardization of large weights of Bureau of Standards. Record form and computation sheet is presented.

WELDING

Boiler. Boiler Welding, Edward H. Heidel. Acetylene Jl., vol. 23, no. 9, Mar. 1922, pp. 431–435 and 470, 15 figs. Gives restrictions placed on locomtives boiler welding known as A.R.A. restrictions. Directions for autogenous, electric and gas welding of boiler parts.

Hyde Process. Hyde Welding Process, D. Richardson. Welding Engr., vol. 7, no. 3, Mar. 1922, pp. 32–34. Describes method of uniting iron and steel which partakes of nature of both welding and brazing, consisting of uniting surfaces by means of molten copper, the copper impregnating mass of metal to be joined.

Job. Some Problems of the Job Welding Shop, S. W. Miller. Am. Welding Soc. Jl., vol. 1, no. 2, Feb. 1922, pp. 42–46. Difficulties in repair work in welding shop are said to be in work itself; in varied natures of metals that are of same general type; financial problems; and guarantees on work.

Locomotive Fireboxes. Welding Firebox Seams. Ry. Rev., vol. 70, no. 12, Mar. 25, 1922, pp. 429–430. Editorial endorsing objections of Bur. of Locomotive Inspection to autogenous welding of firebox seams.

WIND TUNNELS

Massachusetts Institute of Technology. The Aerodynamical Laboratory of the M.I.T., Edward P. Warner. Aviation, vol. 12, no. 11, Mar. 13, 1922, pp. 308–310, 3 figs. Recent additions of two new wind tunnels greatly increase operating capacity of America's oldest research establishment. Constructional details.

MECHANICAL ENGINEERING

Volume 44 July, 1922 Number 7

Some Notes on Railway Refrigerator Cars

A Collection of Facts Relating to Principles of Railway Refrigerator-Car Operation and Information About Various Types of Cars and Methods of Design and Construction

By W. H. WINTERROWD,[1] MONTREAL, QUEBEC, CANADA

An efficient and economical railway refrigerator car is one which provides adequate air circulation, adequate protection to the lading, adequate quantity and degree of refrigeration, quick initial cooling, uniform temperature, dry air, space to permit proper methods of loading, and good car construction to minimize maintenance and increase time in service.

The literature of this subject being to some extent scattered, this paper is an attempt to include under one heading some of the most interesting and important facts regarding principles and methods involved in railway refrigerator-car operation, as well as to present some information regarding the types of cars and methods of construction used by various railways and private-car owners.

The data were collected directly from the railways and private-car owners in an endeavor to sense the general trend of design and construction, and as there are signs on the horizon which indicate a renewed activity in the construction of railway equipment, this information is presented in the hope that it will serve to reëmphasize the great importance to the railways of efficient and well-maintained cars of the refrigerator type.

THE importance of efficient and well-maintained railway refrigerator cars to the people and railways of North America cannot be overemphasized. The *Railway Equipment Register* for March, 1922, shows that the railways and private-car owners own approximately 153,000 cars of this type; figures from the same source indicate that this is about 6 per cent of all the cars owned, and approximately 13 per cent of all the box- or house-type cars listed.

Refrigerator cars are important in the life of the people because they are used principally to carry the bulk of the nation's perishable food-stuffs. They are important to the railways because they are factors in the production of revenue. When hauls were short and the variety of perishable commodities few, the problem of transporting and protecting the commodities from heat or cold was comparatively simple. Increasing distances and a greater variety of perishables not only made necessary greater numbers of, and more efficient, cars, but involved the establishment of railway divisional and terminal facilities, upon which the successful operation of this type of equipment is contingent.

In this paper the author has attempted to include under one heading some of the most interesting and important facts regarding principles and methods involved as well as to present some information regarding the type of cars and methods of construction used by various railways and private-car owners. The data were collected directly from the railways and private-car owners in an endeavor to sense the general trend of design and construction, and as there are signs on the horizon which indicate a renewed activity in the construction of railway equipment, this information is presented in the hope that it will serve to reemphasize the great importance to the railways of efficient and well-maintained cars of the refrigerator type.

The information which follows deals entirely with cars in which refrigeration is obtained by means of ice and salt. Many interesting efforts have been made to evolve a mechanical means of refrigeration, but the problem has been difficult of satisfactory and economical solution.

Refrigeration of Commodities in Transit Involves Many Factors

The prevailing method of obtaining refrigeration is by means of naturally circulated air cooled by contact with ice, or ice and salt, placed in suitable receptacles called bunkers located at each end of an insulated car. Some modifications of this system will be touched upon very briefly later.

Circulation is assisted and made most efficient by means of insulated partitions, called bulkheads, placed in front of the containers and so constructed that the relatively warm air must pass over the top of them to reach the ice, or ice containers. The air becoming chilled, and therefore heavier, sinks toward the floor and reaches the body of the car by passing through a space beneath the bulkheads.

These insulated partitions also assist in protecting the lading nearest the ice containers. Without bulkheads, and when salt is used with the ice to hasten and increase refrigeration, that part of the lading nearest the ice frequently freezes, an undesirable and disastrous occurrence with some commodities. At the same time that portion of the load near the center and top of the car may remain at too high a temperature, an equally undesirable condition.

As a further aid to circulation, particularly in cars where the lading is piled or stacked, a slatted wooden structure known as a floor rack is of very great value. These racks, on the top of which the lading may be placed, consist of longitudinal runners 3 or 4 in. high, with cross-slats fastened to the top of them. They are hinged to the side walls of the car and are divided in the middle so that they can be turned up to make the floor accessible. These racks permit the cold air which flows beneath the bulkhead to circulate freely toward the center of the car and up through the lading.

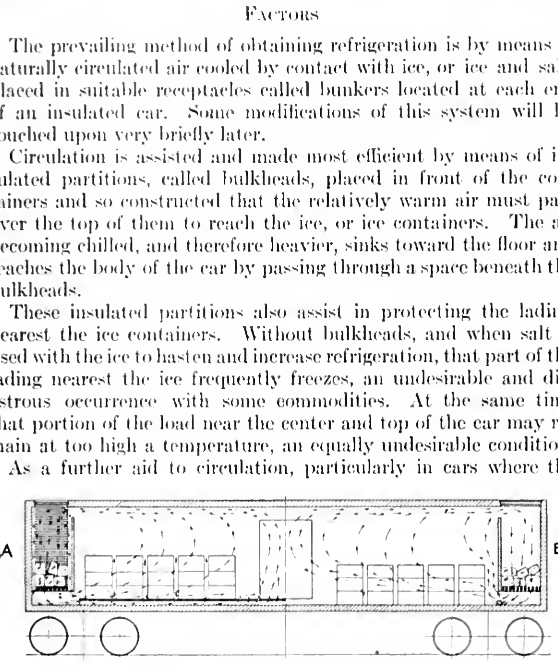

Fig. 1 Diagram of Air Circulation

Illustrations of Effect of Design

The "A" end of the car, Fig. 1, shows the relative arrangement of bunkers, bulkheads, and floor racks, and the resultant trend of air circulation.

It is highly desirable that there be no obstruction to the flow of cold air where it passes beneath the bulkheads. The "B" end of the car, Fig. 1, shows how an obstruction at that point can act as a dam or deflector of the air currents, and partly or entirely defeat the object of the floor racks, and even cause frosting of the lading against the insulated bulkhead. If floor, bunker, or splashboard construction necessitates a ledge beneath the bulkhead, it should be kept as low as possible and the floor rack and bulkhead so designed to provide sufficient area for a free flow of air. At the "B" end the lading is shown piled directly on the floor and the air currents directly indicate the advantage of floor racks.

---

[1] Chief Mech. Engr., Canadian Pacific Railway Co. Mem. Am.Soc.M.E.

Abridgment of a paper presented at a joint meeting of the Metropolitan Section and the Railroad Division of the A.S.M.E., and the A.S.R.E., New York, May 16, 1922. All papers are subject to revision.

To obtain the greatest advantage from circulation, the contents of the car should be loaded so that the air can come in contact with a maximum surface with a minimum of restricted circulation. It is easy to understand that boxes or containers placed closely against each other and against the walls of the car cannot be cooled quickly or properly preserved at as uniform a temperature as when placed so that air can flow between them, or generally speaking, throughout the entire load.

The temperature of the circulating air is affected by the type and size of ice containers or bunkers. The chief considerations in the construction and capacity of the bunkers are the refrigeration required to replace the loss due to transmission and the refrigeration required to cool the car quickly and maintain its contents at the required temperature. The loss in transmission in turn depends upon insulation, car construction and maintenance; factors which will be more fully discussed later.

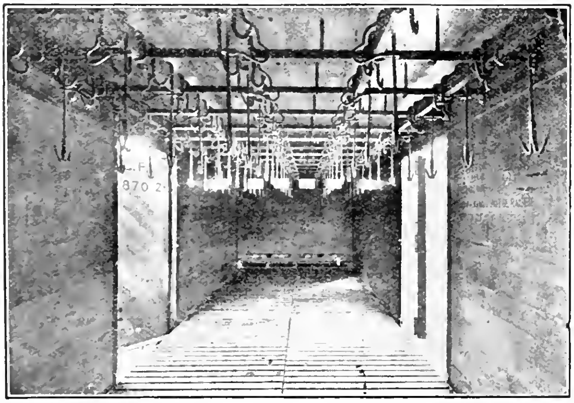

Fig. 2 Meat Rack and Hook Installation

A basket bunker is shown in the "A" end of the car in Fig. 1, and a box bunker in the "B" end.

The sides of the basket bunker are constructed of wire mesh. The bottom consists of a slatted wooden structure. The bunker is placed in position so that air space exists around the outer surfaces, this construction permitting the air behind the bulkhead to come in contact with a maximum ice area, while the open spaces around the bunkers facilitate circulation.

The bottom of the box bunker shown at the "B" end of the car in Fig. 1 is also slatted. The walls are formed by the bulkhead and by the sides and end of the car. In an endeavor to make the refrigerator car more productive and useful for general purposes, some builders have applied collapsible box bunkers. In this design the bulkhead is swung up, or to one side, and fastened. The slatted rack is swung or folded back against the end of the car. In this way the space occupied by the bunker is made available for general lading.

Another very important factor is the size of the car and its proportions, particularly with reference to the distance between the bulkheads. If this distance is too great, the air may not be at a low enough temperature when it reaches the center of the car to properly refrigerate the load at that point, particularly near the top of the car. Under such conditions a portion of the load near the bulkheads may be sufficiently chilled while the upper and center part of the load may be too warm.

Importance of Temperature of Entering Load

If heat is not removed from certain commodities prior to loading it is highly desirable to remove it as quickly as possible after loading. Tests and general experience show that if the heat is not promptly reduced, the commodities either spoil en route or reach their destination in such condition that their market value is greatly reduced. Quick cooling after loading is generally attempted by precooling the car, by the use of cars in which maximum and most efficient air circulation can be obtained, and by mixing a proper amount of salt with the ice or by placing coarse rock salt on top of the ice.

Precooling the car may be accomplished by the use of ice and salt, but at many points where a large tonnage of fruit or meat originates, the cars as well as the lading are often precooled by mechanical means.

Precooling means less ice in transit, a matter of economy to shippers and railways alike. Some commodities can be frozen hard and therefore require little or no icing en route, the lading itself supplying the necessary refrigeration. This not only insures better condition in transit but is an added economy.

Humidity or moisture content of the air in the car is almost as important as temperature. Generally speaking, if refrigeration is effective and a high initial rate of cooling obtains, the air is kept sufficiently dry due to condensation taking place on the surface of the ice, or ice containers. In this way the moisture given off by some classes of lading is also deposited. Excess of humidity, if not fatal, is highly injurious to many commodities.

Insulation the Most Important Consideration

Finally we come to the matter of insulation, the most important factor in connection with efficient and economical refrigeration in a railway car. The function of the insulation is to afford protection to the lading by minimizing heat transmission through the walls, roof, and floor of the car. To do its work properly it must be by nature a poor conductor of heat. Other desirable qualifications are reasonable cost, strength, adaptability, durability, light weight, and imperviousness to moisture.

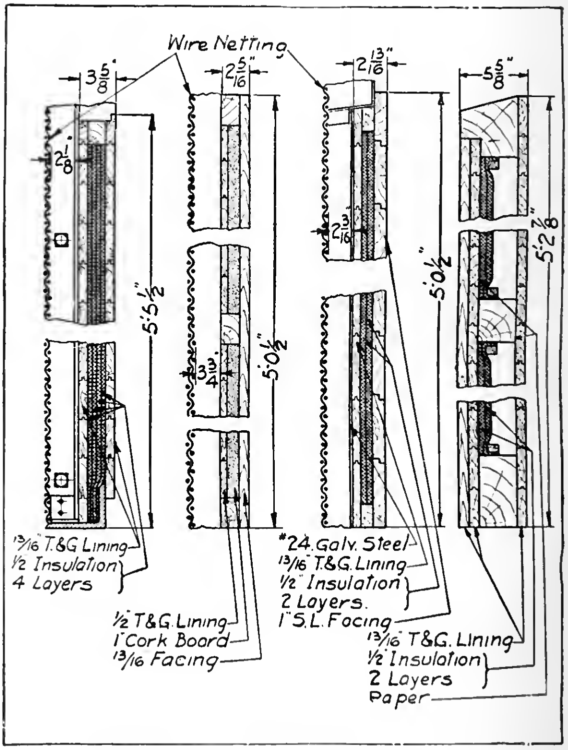

Fig. 3 Cross-Sections of Bulkheads

This subject might well be divided into two parts, insulating materials and insulation, because the general subject involves methods of car construction and maintenance in addition to the consideration of materials and principles of heat transmission.

The whole subject is capable of analysis, but that the principles involved are not broadly known is indicated by the fact that in very recent years cars have been built without proper or sufficient insulation. These cars, which do not properly protect their lading, are huge consumers of ice and expensive to operate and require a great deal of maintenance to keep them in service.

It is evident from the foregoing that an efficient and economical

railway refrigerator car is one which provides adequate air circulation, adequate protection to the lading, adequate quantity and degree of refrigeration, quick initial cooling, uniform temperatures, dry air, space to permit proper methods of loading, and good car construction to minimize maintenance and increase time in service.

SOME NOTES ON EXISTING CARS

In an endeavor to sense the trend of refrigerator-car design, proportions, and construction, the author addressed an inquiry to a number of railways and private-car owners. The replies, while not complete, were very generous. A comparison of the most interesting returns is shown in Table 1, and makes a very interesting study, although in any consideration of this table the fact must not be overlooked that possibly some of the railroads or owners, if building equipment today, might modify their designs.

Every road or owner represented owns at least one thousand cars. As far as possible the cars shown were chosen from quantities built in comparatively recent years.

Types of Cars and Ice Containers

Generally speaking, the cars can be divided into two types: one equipped with brine tanks and generally used for carrying meats; the other, equipped with bunkers and used principally for carrying commodities such as eggs, butter, vegetables and fruit.

In connection with this distinction, based on ice containers, it is interesting to note that Dr. Pennington has stated that a car of the basket-bunker type, such as the U. S. Railway Administration Standard, will carry meat hung from rails quite as successfully as a car built especially for meat. The statement is also made that there is not visible in practical results the advantages supposed to accrue from the retention of the brine, provided coarse rock salt is place on top of the ice in the bunker and so forced to bore its way through the whole mass before finding an exit.

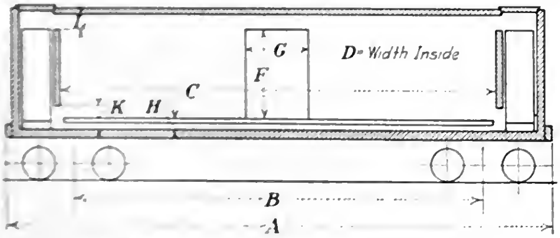
But there is a very important problem in this connection that must not be overlooked if salt is to be used with ice in a basket bunker, and that is the method of disposing of the brine. It is common knowledge that if brine falls on journal boxes, side frames, arch bars or other truck parts, as well as upon rails, tie plates, bridge members, etc., the resulting damage is great and a factor involving heavy maintenance cost.

The subject is so important that the American Railway Association interchange rules specify that after July 1, 1922, no car carrying products which require for their refrigeration the use of ice and salt and which are equipped with brine tanks, will be accepted in interchange unless provided with a suitable device for retaining the brine between the icing stations.

Twenty-seven railroads and owners are represented in Table 1. Out of this number the principal cars of sixteen are equipped with bunkers and the remainder with brine tanks. Out of the sixteen, eleven or practically 69 per cent are of the basket type; the remaining five, or approximately 31 per cent, are of the box type. The majority of the cars recently built, or now under construction are equipped with the basket type of bunker. The demand for refrigeration and the special-service car, as well as greater efficiency of the permanent basket type, appear to be decreasing the demand for the collapsible bunker.

Another distinction that prevails and will prevail as long as cars are built for some particular service is the difference in construction due to the commodity to be transported.

In meat cars the lading is hung on hooks suspended from a meat rack placed just below the ceiling. This rack generally consists of stringers and cross-bars supported by the roof and walls of the car. In a car of this type it is necessary to make the framing heavier so that in addition to its other functions it will adequately support the weight of the lading. A meat rack and hook installation is illustrated in Fig. 2. Very often additional lading is stowed or placed on the floor racks beneath the suspended load, in order to obtain the full carrying capacity of the car.



Sketch Showing Dimensions Referred to in Table 1

Bulkheads.—The majority of the cars tabulated are equipped with solid bulkheads. These are either built into place or are hinged from the walls or ceiling so that they can be swung open. A few cars, however, are equipped with the syphon system, in which the bulkhead consists of a framework holding a series of galvanized iron louvres supposed to direct the air back and down into the bunkers.

The general trend seems to be to use two layers of $^1/_2$-in. hair felt between two walls of $^{1}/_{16}$-in. matched-and-dressed wood lining. An interesting exception, and on a quite recent car, is the use of one layer of 1-in. cork insulation. Some bulkheads are constructed of two walls with a few layers of waterproof paper between them. Occasionally an air space is contained between the walls. In one instance, in addition to a dead-air space, two layers of $^1/_2$-in. hair felt are provided. Some cross-sections of bulkheads are shown in Fig. 3.

Space Below Bulkheads. The space between the bottom of the bulkhead and the car floor varies considerably, ranging from 7 in. to 2 ft. 7 in. On the car with the 7-in. space the bulkhead is brought right down to the level of the floor rack. On the bottom of this bulkhead a canvas strip is fastened to prevent cold air passing out above the racks. The cars with the very large openings at both bottom and top of bulkheads are generally used for meat shipments.

The majority of cars have a bottom opening of from 9 to $15^3/_4$ in. The average is about 12 in.

As the floor racks on these cars average about $4^1/_2$ to 5 in. in height, it can be seen that the cold air has access to the body of the car above the rack as well as through the space beneath it.

The author has endeavored to ascertain if there is any relation between the size of the openings above and below the bulkhead and the velocity of the air in circulation, but inquiry has not produced anything definite. There is some unanimity of opinion, however, in favor of the design in which there is an opening of from 2 to 7 in. above the floor racks.

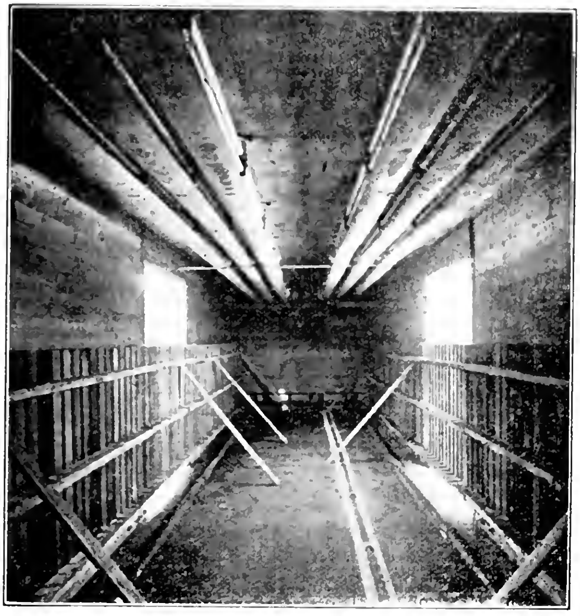


Fig. 4 Interior of Car with Overhead Brine Tanks; Showing also Heater Pipes on Floor

In the matter of efficient refrigeration the distance between bulkheads is an important one. The tabulation shows that this varies between 28 ft. 8 in. and 38 ft. 10 in. The general trend is between 32 and 34 ft. On the latest cars the spacing is approximately 33 ft., or slightly greater. The size of the standard egg crate has been a large factor in the establishment of the exact dimension.

Car Construction and Maintenance

An impression seems to prevail that the life of a railway refrigerator car is about six to eight years. In 1919 a committee of the Mechanical Section of the American Railway Association reported that the average life of railroad-owned wooden refrigerator cars, dismantled was 17.1 years, and of private-line wooden refrigerator cars, dismantled, 21.9 years, making the average life for all wooden refrigerator cars, dismantled, 19.4 years.

The life of refrigerator cars equipped with steel under-frames or steel framing and superstructure is a matter upon which there are few data, because such cars are comparatively modern. There seem to be no reasons, however, barring those of possible evolution, why such cars should not have a long life and require little for maintenance by reason of their better design and construction.

It is not difficult to appreciate the causes responsible for the high cost of maintenance of old wooden cars; the refrigerator type does not stand alone in this class. But in addition to more severe traffic conditions, this type of car had required attention on account of the difficulty in keeping moisture away from the insulation as well as from the wooden framing and flooring. If the insulation becomes broken, wet or sags so that air can circulate around it, the car rapidly loses its efficiency. Table 1 and the cross-sections in Figs. 5 to 13 inclusive, give a general idea of some types of cars, and what has been done to improve design and construction. Figs. 12 and 13 represent cars of relatively low efficiency. Figs. 5 to 11, inclusive, show more modern cars and indicate the more recent trend in the matter of improved insulation and general construction.

Table I Refrigerator Cars

The cross-sections really speak for themselves, but a brief discussion under the separate headings Floors, Walls and Roofs will be of some interest.

Floors.—The chief problem in floor construction is to make the structure waterproof, as well as a good insulator.

The insulating value of all materials that absorb moisture is greatly decreased when water is absorbed. In addition, water causes most of the insulating materials popular in refrigeration construction to become mushy and sag or drop out of place. It also causes wood floors lining and framing to decay or weaken, thereby making it more difficult to keep the general structure tight.

Nearly all the modern or at least recently built floors employ a construction involving cork as an insulating material. To keep moisture away from the cork various waterproofing compounds or waterproof materials are used.

The one exception to this general trend is shown in Fig. 11, where the insulation consists of four massed layers of $^1/_2$-in. hair felt. Moisture is kept away from the top of the insulation by means of two layers of floor boards between which is laid a layer of waterproofing compound. The surface of the top floor is covered with a layer of waterproofing compound into the surface of which sand has been rolled.

Figs. 12 and 13 show a floor insulation with intervening dead-air spaces. To be insulators, however, they must be dead-air spaces; for once circulation starts their efficiency is destroyed.

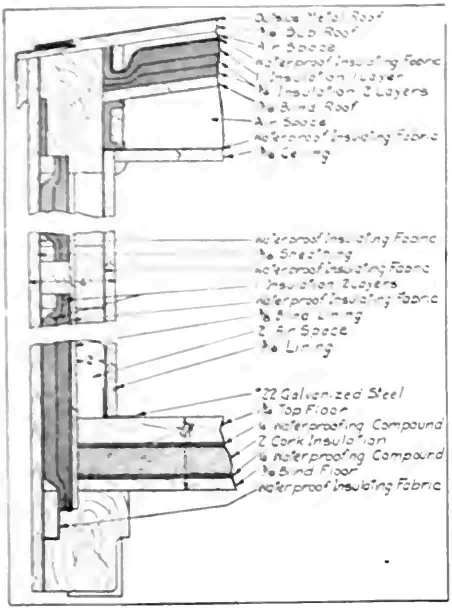

FIG. 5

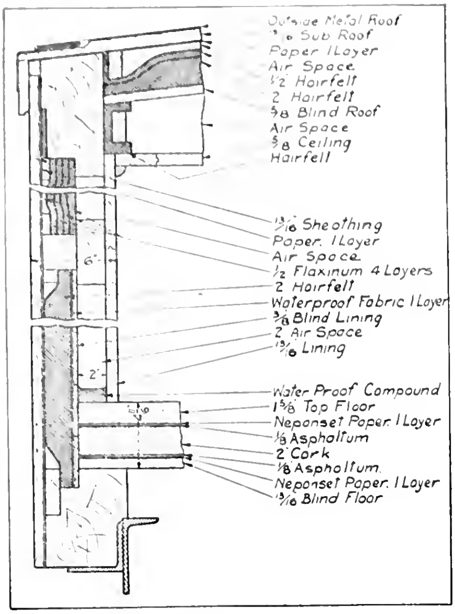

FIG. 6

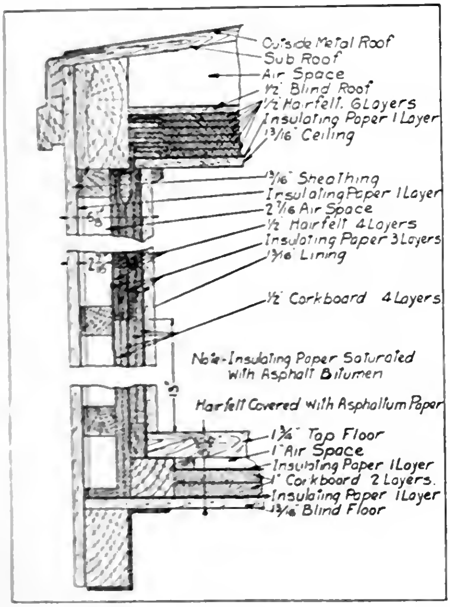

FIG. 7

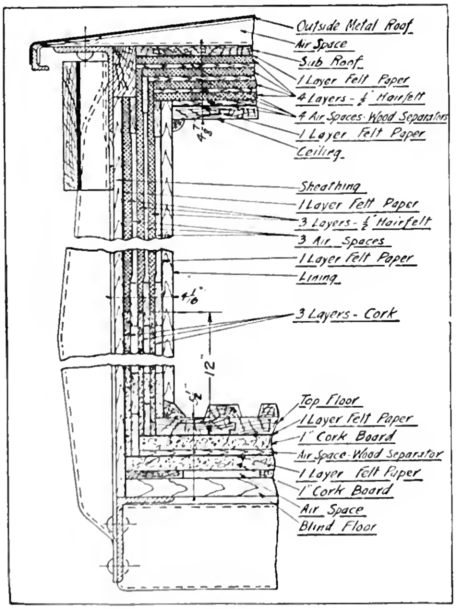

FIG. 8

FIGS. 5 TO 8 TYPES OF REFRIGERATOR CARS

It has been intimated that in some cases cork as a floor insulator has not been entirely satisfactory because in time it becomes brittle and crumbles. Specific information on this subject would be very valuable, as it would indicate whether the trouble was inherent or due to some particular method of construction.

Walls.—In connection with a waterproof structure it is interesting to note the various methods employed at the junction of the floor and side walls to keep water from getting past the lining and into the insulation. This point has been a source of great trouble. Some particularly interesting methods of construction at this point are shown in Figs. 6, 9, 10 and 11.

An exceedingly interesting example of waterproof construction is con-

tained in some all-steel refrigerator cars designed by W. F. Kiesel, Mem. Am.Soc.M.E. Mechanical Engineer of the Pennsylvania Railroad. The proportions of these cars were described in the *Railway Review* of February 3, 1917. The body of the car consists of an all-steel container placed within an outer container, the space between the walls being filled with insulation. The writer understands that at the floor the sections of the inner container are welded together, thus making the floor practically one piece and watertight and thereby affording maximum protection to the insulation.

Inspection of the various cross-sections indicates a general trend toward massing wall insulation and eliminating air spaces between the layers of insulation. As a rule the insulation is applied in a continuous strip from door post to door post. The advantage of applying insulation in this way lies in the fact that a continuous or unbroken surface presents no joints or openings through which air can pass or circulate. It has been the experience that where insulation is applied in sections, unusual construction is required to prevent eventual air circulation. Wall insulation is rarely less than 2 in. thick on the most recent cars. In some cases this insulation is applied in two massed layers. In one case the single layer is 2 in. thick. In the majority of cases four massed layers of 1/2-in. insulation are used.

The construction employed by the U. S. Railway Administration is indicated in Fig. 5 and shows the insulating material massed beneath the outside sheathing. Air space is provided between the inner lining and the blind lining. This construction was advocated as a method of preventing damage to the insulation should nails be driven through the inside lining.

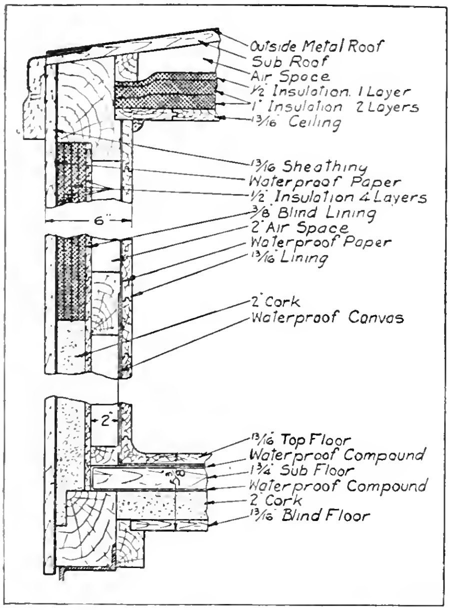

Fig. 9

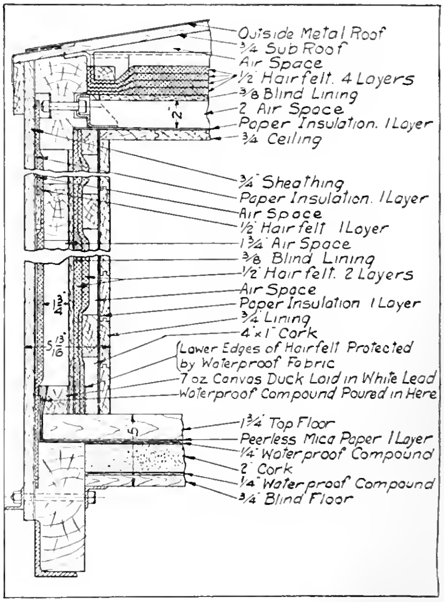

Fig. 10

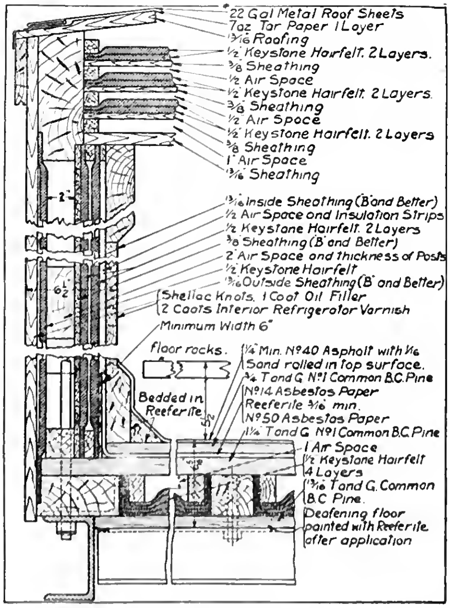

Fig. 11

Figs. 9 to 11 Types of Refrigerator Cars

A great many cars are insulated in this way, but there are some interesting exceptions, one of which is shown in Fig. 7. The advantage claimed for such construction is that of a car becomes cornered or damaged to such an extent that sheathing is cut or broken, the insulation stands a much better chance of remaining intact or becoming only slightly damaged, and the lading not subjected to risk caused by loss of cold air. It is also claimed that by the use of properly constructed wood forms or spacers, and the proper loading methods, no necessity should exist for driving nails through the inside lining. A great many railroads are conducting an educational campaign in this connection. Two interesting wall structures are shown in Figs. 7 and 8. In these figures it will be seen that layers of cork board are used below the insulation, the hair felt starting at a point 13 in. above the level of the floor.

Another arrangement in which cork is used is shown in Fig. 10. In this cross-section the two inner and massed layers of hair-felt insulation come right down to the floor level. A slab of cork board is placed between the hair felt and the inner lining. The hair felt is protected at the floor line with canvas duck laid in white lead. The bottom of the insulation behind the sheathing is protected by waterproof compound poured into a channel or gutter provided for the purpose. The compound in this gutter joins the compound laid above the flooring cork thus forming a continuous waterproof section.

Roofs.—The tendency at present is to apply massed insulation in the roofs. As a rule the most modern cars have 2 to $2^1/_2$ in. of insulation applied in this way. The car shown in Fig. 7 is provided with 3 in. of such insulation.

Some cars are equipped with a carefully designed double-board roof with waterproofing compound between the layers. There are many advocates of this type of roof, but it is interesting to note the number of outside metal roofs that are applied to cars of this type. The advocates of the outside metal roof claim a saving in weight and greater protection to the sub-roofs and insulation from moisture, claiming that with proper insulation the metal roof has no effect on the interior temperature of the car.

Doors and Hatches.—Doors and hatches are being made with more insulation and are being strongly and properly constructed so that they will fit the door openings tightly, and not permit any loss of refrigeration due to leakage. In this connection, any other openings into the car should be so constructed that they can be kept tightly in place and easily maintained. An efficient door-locking device is no small item in keeping doors tight and thereby maintaining the efficiency of the car.

Painting.—Refrigerator cars should be kept well painted in order to preserve all exterior surfaces. This is in the interest of obtaining long life for the car. Metal parts should be given particular attention in this respect.

The author believes that refrigerator cars should be painted with a light or non-heat-absorbing color. Dark colors absorb heat. An inquiry addressed to the owners of white and yellow cars indicated that no specific data existed on the subject, but it was the general belief that the light colors were an advantage in this respect.

Insulation

It has been stated that the function of the insulation is to afford protection to the contents of the car by minimizing heat transmission through the walls, roof, and floor. A good insulator must not only be a poor conductor of heat but must be a material having the qualifications of reasonable cost, adaptibility, durability, light weight, imperviousness to moisture, freedom from odors, and be proof against vermin. In any study of insulating materials for use in railway refrigerator cars, these factors must all be kept in mind.

TABLE 2 THERMAL CONDUCTIVITY OF INSULATING MATERIALS

Material	Remarks	Thermal Conductivity [1]	Density [2]
Air	If no heat is transferred by radiation or convection	4.2	0.08
Calorax	Fluffy mineral powder	5.3	4.0
Kapok	Hollow vegetable fibers, loosely packed	5.7	0.88
Pure Wool		5.9	6.9
Pure Wool		5.9	6.3
Hair Felt	Fibers perpendicular to heat flow	5.9	17.0
Pure Wool		6.3	5.0
Slag Wool	Loosely packed	6.3	12.0
Keystone Hair	Hair felt and other fibers, confined with building paper.	6.5	19.0
Mineral Wool	Loosely packed	6.5	12.0
Cornboard	No artificial binder, low density	6.5	6.9
Mineral Wool	Fibers perpendicular to heat flow	6.9	18.0
Cotton Wool	Medium packed	7.0	5.0
Pure Wool	Very loose packing, probably air circulation through material	7.0	2.5
Insulite	Pressed wood pulp	7.1	12.0
Mineral Wool	Firmly packed	7.1	21.0
Linofelt	Vegetable fiber confined with paper, flexible and soft	7.2	11.3
Ground Cork	Less than $\frac{1}{16}$ in.	7.4	9.4
Cornboard	No artificial binder	7.3	9.9
Balsa Wood	Very light wood, across grain	7.5	7.1
Balsa Wood	Same sample with 13 per cent waterproofing compounds	8.3	8.0
Flaxlinum	Felted vegetable fibers	7.9	11.0
Fibrofelt	Felted vegetable fibers	7.9	11.0
Rock Cork	Mineral wool and binder	7.9	16.0
Balsa Wood	Across grain, untreated	8.3	7.4
Cornboard	With bituminous binder	8.4	16.0
Balsa Wood	Medium weight wood	9.2	8.8
Sawdust	Various	9.7	12.0
Air Cell (½-in.)	Corrugated asbestos paper, enclosing air spaces	11.0	8.8
Air Cell (1-in.)	Corrugated asbestos paper, enclosing air spaces	12.0	8.8
Asbestos Paper	Built up of thin layers	12.0	31.0
Balsa Wood	Heavy	14.0	20.0
Fire Felt Sheet	Asbestos sheet coated with cement	14.0	26.0
Fire Felt Roll	Flexible Asbestos sheet	15.0	43.0
Cypress	Across grain	16.0	29.0
Asphalt Roofing	Felt saturated with asphalt	17.0	55.0
White Pine	Across grain	19.0	32.0
Mahogany	Across grain	22.0	34.0
Oak	Across grain	24.0	38.0
Maple	Across grain	27.0	44.0
Virginia Pine	Across grain	23.0	34.0

[1] Thermal Conductivity in B.t.u. per day (24 hr.) per sq. ft. per deg. fahr. per in. thickness

[2] Density, lb. per cu. ft.

A material with low thermal conductivity, but one which is difficult to apply economically, is undesirable. On the other hand, there may be materials easy to apply but which will not stay in place or which will not retain their insulating value under service conditions; these are equally undesirable. In addition the material should be of a kind easily handled as well as easily applied.

It seems to be generally conceded that the best insulating materials are those which contain a very great number of minute dead-air cells, or interstices containing dead air. If these air cells become filled with moisture, the thermal conductivity of the material is increased. This is one of the reasons why it is so important to protect insulation from water, and why it is desirable to use a material highly resistant to moisture.

Some materials when subjected to moisture fall out of place or sag, and if a large air space, or pocket, is not formed, air circulation frequently results, the effect of which greatly decreases the efficiency of the car.

Thermal Conductivity.—The subject of heat transmission through the walls of a railway refrigerator car is one upon which there is some difference of opinion, this difference dealing largely with variables or factors which have not yet been reduced to absolute terms.

In calculating heat transmission through a compound wall it is essential to know the thermal conductivity of the various materials contained in the structure.

The most recent determinations of thermal value of various materials are shown in Table 2, taken from a paper on The Thermal Conductivity of Heat Insulators, by M. S. Van Dusen, in the October, 1920, Journal of the American Society of Heating and Ventilating Engineers.

Péclet's formula for the total heat transmission through a compound wall is

$$H = \frac{1}{\frac{1}{K_1} + \frac{D}{C} + \frac{D_1}{C_1} + \frac{D_2}{C_2} + \text{etc.} + \frac{1}{K_2}} \quad \ldots\ldots\ldots\ldots [1]$$

in which

H = Heat transmitted per sq. ft. per hr., B.t.u.
K_1 = Inner surface conduction
K_2 = Outer surface conduction
D, D_1, D_2, etc. = Thickness of each element in wall, in.
C, C_1, C_2, etc. = Thermal conductivity (per hour) of elements corresponding to thickness D, D_1, D_2, etc., per in. thickness per sq. ft. per deg. fahr.

If the difference between inside T_1 and outside T_2 temperatures is considered, Equation [1] should be multiplied by $(T_1 - T_2)$ and becomes

$$H = \frac{T_1 - T_2}{\frac{1}{K_1} + \frac{D}{C} + \frac{D_1}{C_1} + \frac{D_2}{C_2} + \text{etc.} + \frac{1}{K_2}}$$

The thermal conductivity of each material shown in Table 2 is stated in B.t.u. per day.

In the formula, thermal conductivity C, C_1, C_2, etc., is stated in B.t.u. per hour. To be used in the formula each thermal-conductivity figure in the table must be divided by 24 to bring it to the required hourly basis. For example, Table 2 shows the thermal conductivity of white pine wood as 19.0. In this case C for white pine is $C = 19/24 = 0.790$.

Available information indicates that in the original formula $1/K_1$ was 2.0, but modern practice indicates this to be too high a value. It is felt that by assigning a value of 0.5 to $1/K_1$ refrigerator-car conditions are very nearly approximated, and this value is taken in the calculations mentioned below.

$1/K_2$ is a factor generally conceded to have a value so small that it can for all practical purposes be eliminated from the equation.

In order to illustrate the application of the formula, as well as to indicate the difference in the efficiency of walls, roofs and floors in cars of different design, calculations are given in the complete paper of the car cross-sectioned in Fig. 5, which is used as an illustration of good construction and relatively high efficiency. The car shown in Fig. 12 is used in comparison in order to show the greater rate of heat transmission or lower efficiency caused by different methods of insulation and construction. The comparative results are given in Table 3.

Materials and Workmanship

Proper materials are a very important factor in refrigerator-car construction. The right grade of lumber should be used wherever required, and it should be properly dried before being placed in the car. Workmanship should be of the best. Insulation should be handled carefully, care being taken to see that it does not become torn or damaged.

Lumber which has received preservative treatment has been given considerable attention by car builders and car owners for several years, and much of it is now in service. Sufficient time has not elapsed to indicate what increased life can be obtained, but experience to date indicates treated lumber to be more durable and a kind that will resist moisture and decay.

No objection can be made to it on account of any odor caused by treatment. In treating, the lumber is submerged for a number of hours in hot creosote oil, after which it is placed in a drip rack and permitted to drain. It is estimated that this treatment will result in large saving, doubling the life of the roofing boards and sills, and effecting considerable saving in labor that would otherwise be necessary to properly maintain these parts in the course of time.

An interesting report in connection with the use of treated lumber for use in the construction of cars was presented recently before the American Wood Preservers' Association. This report calls attention to the fact that decay is the principal cause of failures in lumber, and that great economy is possible by the use of a preservative.

It is evident that if some of the wooden parts of a refrigerator car can be made moisture-proof or highly resistant to moisture, the efficiency of the car can be maintained at a much higher average.

The author has been advised that some refrigerator cars are in service in which balsa wood is the principal insulating material. This wood is very light in weight having in its natural state a density of 7.1 lb. per cu. ft. It is a South American wood that grows very rapidly, and is of cellular structure. Table 2 shows it to have a thermal conductivity of 7.5 in its natural state and 8.3 when treated with waterproofing compounds.

It would be of great interest to know if treated or untreated balsa wood is used between the ordinary walls of a car as insulation, or if the material figures largely in the construction of the superstructure of the car, such as lining and sheathing. Its strength is insufficient for its use in framing.

TABLE 3

Comparison of B.t.u. per sq. ft. per deg. diff. fahr. per 24 hr. in cars shown in Fig. 14 and Fig. 23.

	Including Air Space		Excluding Air Space	
	Fig. 14	Fig. 23	Fig. 14	Fig. 23
Roof	1.702	2.328	1.953	3.12
Wall	2.172	2.80	2.388	3.768
Floor	2.46	2.544	2.46	3.21

It would also be of interest to know if the material is durable and efficient in this class of service, if any modification of car structure is necessary for its use, and if any reduction of car weight can be accomplished by its employment.

Other Systems of Refrigeration

In the cars described in the cross-sections and tabulation, refrigeration is accomplished by means of air circulation, the air being cooled by contact with ice or ice containers placed at the ends of the car.

One modification of this system is a car in which ice containers are placed just below the roof and in the center of the car. In this system it is claimed that maximum refrigeration can be applied where the air within the car is at its highest temperature.

There do not appear to be a great number of cars of this type in modern service. The principal objections to such a system are decreased head room in the center of the car, weight of ice near the roof of the car, and difficulty of adapting this system for use with meat racks placed below the ceiling of the car.

Another system consists of a brine tank built into the roof at each end of the car. These tanks extend about 9 in. below the ceiling and are heavily insulated on top, sides and bottom. The tanks at each end of the car are connected to each other by pipes hung about 2 or 3 in. below the ceiling. The pipes are not insulated. In each tank is a partition running lengthwise of the car. In one partition are some check valves opening to the right; in the other partition some check valves open to the left. The theory is that when ice and salt are placed in the two tanks the swaying of the car in motion automatically circulates the brine through the pipes, refrigeration being accomplished by contact of the air within the car against the surface of the pipes connecting the two tanks. Comparatively speaking, this system has not been in service a very great length of time. The advantages claimed for it are increased loading space, decreased consumption of ice, uniform temperatures, and a car that can easily be changed from a refrigerator to a heater car. The author understands that these cars are being tested in various fields of service. It would be interesting to have some information regarding the ability of this system to supply refrigeration when the car is not in motion, and what the system can accomplish in the way of quick precooling when the car is placed at the loading shed or platform.

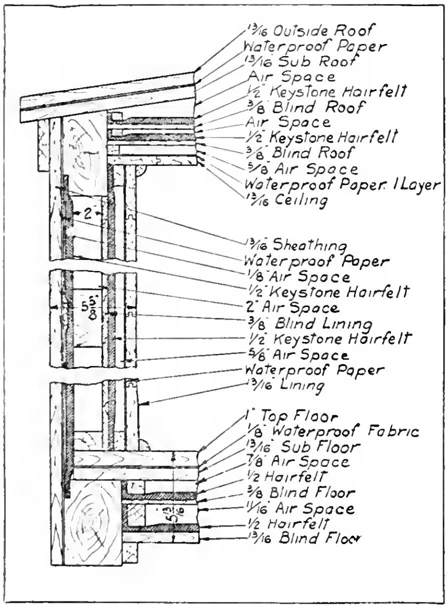

Fig. 12

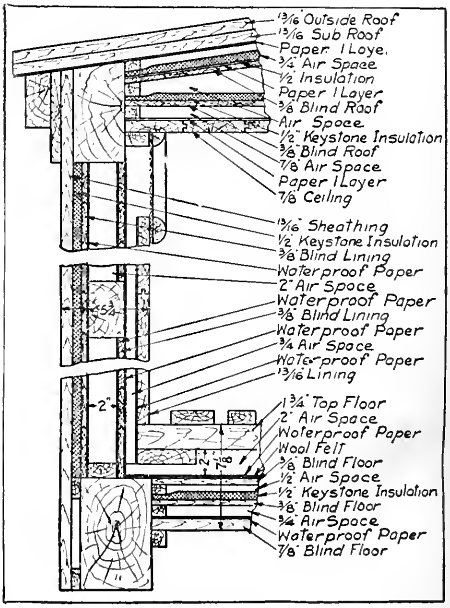

Fig. 13

Figs. 12 and 13 Types of Refrigerator Cars

The interior of such a car is shown in Fig. 4. This illustration shows the floor racks propped up against the side walls so that the piping along the floor beneath the racks can be seen. This piping is used when the system is used to heat the contents of the car. Canvas troughs are placed beneath the piping located beneath the ceiling in order to catch any condensation or frost slush that may drop from these pipes.

Precooling

The importance of precooling the lading and the resulting economy in the use of ice and labor were mentioned in a preceding paragraph. There are two distinct methods of precooling cars and lading. The first is known as shippers' precooling; and the lading is placed in cold-storage rooms in which the proper temperature is maintained, and where the lading is allowed to remain until it cools to the proper temperature, after which it is loaded quickly into cars that have been pre-iced. The second method is known as the carrier's precooling, and generally consists of a system in which the car is loaded, after which the interior of the car and the lading are precooled by mechanical means. In one system of this kind, at a point where a large tonnage of citrus fruit originates, cars are placed at a precooling dock where the ventilator hatches are connected with large air pipes, and the lading is precooled by means of a forced circulation of cold air. The air is brought to a low temperature in the cooling rooms of the plant, and passes through a long concrete tunnel and into a pipe connected to the hatchway at one end of the car. The air passes through the entire length of the car and out through another pipe connected to the hatchway at the opposite end of the car, and thence back to the cooling room through another concrete tunnel. The cold air passes through the car at a rate of 6000 ft. per min. at a temperature ranging from 12 to 20 deg., for a period of 30 min., after which the pipes on the hatchways are reversed and the cold air is forced through from the opposite end of the car. These pipes are reversed every 30 min. for a period of 4 hr. when the process of precooling is complete. It is stated that citrus fruit loaded into the cars at temperatures of from 80 to 90 deg. can be brought down to 45 deg. within this time. After the car is cooled in this manner it is iced to capacity.

Recently a very interesting and large precooling plant has been erected in the vegetable section at Sanford, Florida, and is operated by the shippers. From this section large shipments of celery are made from January until June. After a careful analysis of the desirable points of an efficient precooling plant, the shippers at this point decided to branch into an entirely new field by adopting a novel method of removing the heat from the celery. This consists of causing a large volume of cooled water to flow over the celery. The average temperature of the water used in this plant is approximately 35 deg. fahr., and it has been stated that the temperature of celery can be brought down from 75 deg. to within 2 deg. of the temperature of the water within 20 min. This plant has a cooling capacity of approximately 15 cars per 24 hours.

Another system of precooling involves the freezing of the lading and a precooling of the car by means of a brine-spray system. When commodities can be frozen hard and shipped in a precooled car, refrigeration may be entirely accomplished or helped to a very great extent by the frozen lading.

Great economies are possible due to precooling. Where small tonnage originates little precooling has been done by mechanical methods on account of the high cost of the plant and equipment. Most mechanical precooling is done where large tonnage originates. At such points the shippers frequently combine to build such a plant. Precooling is receiving more and more attention in connection with various commodities and additional economy in the way of ice and labor may be expected.

General Conclusion

The inquiries upon which these few notes on railway refrigerator cars are based indicate that a very great improvement has been made in refrigerator-car construction and design, particularly within the last few years, but there is also evident indication that the field of investigation in connection with cars of this type is still a most fertile one. Some fairly recent cars indicate that subject of refrigeration in transit is not appreciated in some quarters as it should be. The subject of efficient refrigeration is a most important one, because cars that can be kept in continuous service with a minimum cost of maintenance and which are sufficiently efficient to protect the lading in transit, mean dollars and cents to the railways.

The Accuracy of Boiler Tests

By ALFRED COTTON,[1] ST. LOUIS, MO

This paper points out the unavoidable inaccuracies involved in reports of boiler tests and the absurdity of assigning values carried out to the one-hundredth of one per cent to items which cannot possibly be measured so closely.

The various factors which enter into boiler-test computations are taken up one by one and errors which may be made are covered and the best methods of reducing them considered.

The most important elements are of course the determinations of water and coal used, and of steam produced, both as to quality and quantity. It is shown how the error in obtaining the B.t.u. in the coal burned may easily reach 2.5 per cent in either direction, the water evaporated may be at least one per cent out of the way, and hence the efficiency reported may be 3.5 per cent too high or low.

A LARGE proportion of boiler-test reports are presented with heat-balance figures carried to one-tenth and even one-hundredth of one per cent. Those who have had much experience in boiler testing know that such apparent accuracy is impossible at present and therefore misleading. In a heat balance recently published the percentage portion does not add to an even hundred. Since the last item is simply the difference between what is known and 100, why not make it agree? The deviation from 100 makes it appear that the items are very precise indeed.

How accurate is it possible to make a boiler test? To determine this, every item entering into it must be considered.

First consider the measurement of the water. If the water is carefully weighed or measured by suitable meters the amount fed may be ascertained well within plus or minus 1 per cent. If meters are used, they may be calibrated before the test, and perhaps afterward as well, to insure this accuracy. Proper precautions may be taken to prevent leaks from blow-off cocks, in feedwater heaters, and so forth. Care can also be taken to see that the condition of the water in the gage connections is the same at the end as at the beginning of the test. If this is not done, error may be introduced to the extent of 1 or 2 in. due to the difference in the weight of cold water in the gage connections before blowing off, and of hot water afterward. With an eight-hour test run at rating, the error may be more than 1 per cent from this cause.

Quality of Steam—Steam Sampling

Then there is the quality of the steam to be accounted for. The entrained water in the sample can be ascertained very closely, but it is sometimes stated with much greater precision than the observations warrant, or than is necessary. A boiler-test report was seen recently wherein the proportion of water in the steam was given to one-ten thousandth of one per cent!

The temperature of the steam in the expansion chamber of a throttling calorimeter need only be read to the nearest degree; and when averaging the readings, the result need not be expressed beyond one-tenth of a degree. A glance at a steam table will show that the variation is so slight that carrying it further is futile.

But does the sample of steam so examined represent the bulk steam? That is something which is not known, and the more elaborate discussion given in the complete paper seems to show that it is *not even nearly representative.*

The design and position of the sampling tube are matters of some contention. It is accepted practice to perforate the sampling tube and place it horizontally across the pipe. It is probable that entrained water is commonly in such small particles that it is easily carried in suspension at usual steam velocities. Water flowing along the bottom of the pipe is likely to be mostly condensed steam, and is therefore rightly avoided by placing the sampling pipe horizontally.

The A.S.M.E. sampling tube is made of $^1/_2$-in. standard pipe and is provided with twenty $^1/_8$-in. holes arranged in "irregular or spiral rows," and usually in a more or less regular helix. It should be inserted in the steam main "at a point where the entrained moisture is likely to be most thoroughly mixed." The word "likely" is highly commendable.

It is most probable that the design of a steam-sampling device should be somewhat similar to that of a rain gage; and if this is the case, the A.S.M.E. tube is as unsuitable for its purpose as anything which could well be contrived. One of the fundamental requirements in the location of a rain gage is to avoid the proximity of objects which might shelter the instrument or cause eddies. This requirement is ludicrously violated by the downstream holes in this steam-sampling tube. It would appear that the best position for the holes is directly upstream, and that all holes should be in a line facing in that direction instead of being distributed around the tube. For the smaller steam pipes, a smaller number of large holes could be used, placing them at least, say, 3 diameters center to center, and making their total area about equal to the twenty $^1/_8$-in. holes or, say, 0.25 sq. in.

The most accurate results would be attained with such upstream holes if the velocity of the steam entering the holes approximated that of the bulk flow along the steam pipe. Then the steam and water particles would enter the holes with the least disturbance of their general direction, and consequently the sample would be most representative.

It seems reasonable to think that the actual water present in the steam may be very much less than that observed when we use the A.S.M.E. tube.

If there is much priming, the error in determining the amount of water carried over may approach plus or minus 5 per cent of that evaporated. But assuming orderly operation and careful observation, the accuracy of the report on water evaporated may be from plus or minus 1.5 to 2 per cent; but it cannot well be guaranteed to be closer.

Estimating Coal Consumption

The next item to be considered is the coal, and this may easily be weighed well within plus or minus 1 per cent. However, this is but the coal fed to the furnace, and to know the quantity actually burned in relation to the water evaporated, we must be sure that there is the same amount of fuel in the furnace and in the same stage of combustion at the end of the trial as at the start. The only way to find this out is to look at it. Only those who have done this know how impossible it is to accomplish much more than make a careful guess, and it must be done quickly because conditions are changing momentarily. It is not uncommon for different observers to vary in their estimates to the extent of 10 or even 20 lb. of coal per sq. ft. of grate area. In a test during which a total of 250 lb. of coal was burned on each square foot of grate, the error from this source might amount to over 5 per cent. The error will depend on the length of the test, and for 12-hour tests may very reasonably be placed at not less than plus or minus 1 per cent.

Coal Sampling and Analysis

But, unfortunately, this coal weight does not mean anything of itself. We must at least know the weight of *dry* coal; and if the moisture present in the coal is much over 2 per cent, allowance should be made for the heat used to evaporate and superheat it. To find out how much moisture there is in the coal, we must have a representative sample, and then we must analyze it for moisture *while it is representative.* While working down a laboratory sample the coal will either gain or lose moisture. In a warm, drafty room and especially on a warm floor, it will generally lose moisture, perhaps as much as the equivalent of 3 per cent of the coal or even more. While it is properly bottled up, no further change will occur; but at the laboratory, while being finely ground and while weighing samples, further change will undoubtedly occur and this may be either in increase or reduction of moisture. During all these processes of sampling from the coal pile to the laboratory

---

[1] Research Engineer, Heine Boiler Co. Mem. Am.Soc.M.E.

Abridgment of paper presented at the Spring Meeting, Atlanta, Ga., May 8 to 11, 1922, of The American Society of Mechanical Engineers. All papers are subject to revision.

drying oven it does not seem possible to certify the moisture closer than plus or minus 1 per cent, and it may easily be out plus or minus 2 per cent. Taking the alternative method of drying the coal during the test, there is the difficulty of securing a representative sample, for we are now sampling coal which has not been weighed to the firing floor or hoppers; and there is also the further difficulty of crude drying and weighing apparatus. However, this method is likely to be a little more accurate than the orthodox one, and with reasonable care in selecting samples, results may be obtained within plus or minus 1 per cent.

On examining the report of any boiler trial, the first thing looked for is the efficiency at the trial load. Without this, the report does not generally convey information of very much value. To get the efficiency we must know the heating value of the coal; and whether the heating value is found by calculation from the analysis or by the calorimeter, the essential feature is the extent to which the sample is representative. To fully satisfy this requirement it should have come from widely distributed points in the original bulk coal used during the trial. Of course, this condition is very far from being reached even with the orthodox method of quartering down, unless the test is with powdered coal. Still, such a sample is reasonably representative if the work of getting it has been conscientiously done.

Summary of Errors

It is well here to summarize the possible errors and see where they may lead, and this has been done in the following tabulation, keeping them even lower than suggested.

	Error
Coal:	
Weighing	± 0.5 per cent
Estimating amount of fuel in furnace at start and stop	± 0.5 per cent
Total error of weighed coal	± 1.0 per cent
Variation between original percentage of moisture and that in laboratory sample plus failure of sample to truly represent bulk	± 1.0 per cent
Failure of heat-value sample to represent bulk	± 0.5 per cent
Total error in analysis	± 1.5 per cent
Total error in B.t.u. in coal (weight and analysis) on which efficiency is based	± 2.5 per cent
Water:	
Weighing or metering, starting and stopping test, gage glass, leaks	± 0.5 per cent
Failure of sample of steam to truly represent bulk steam as to entrained water	± 0.5 per cent
Total error in water evaporated	± 1.0 per cent

B.t.u. in coal burned may vary 97.5 to 102.5 per cent.
Water evaporated may vary from 99.0 to 101.0 per cent.
Reported efficiency may vary from 99.0/102.5 to 101.0/97.5, or 96.6 to 103.6.

Therefore if the efficiency really attained in any boiler trial is 78 per cent, the report may show as low as 75.4 per cent or as high as 80.8 per cent if all the errors happen to be in one direction. It may be thought that this possible error is placed at a higher figure than occurs in practice; but it must be remembered that generally the errors will be in different directions and so tend to neutralize each other, and it will be seldom that they are all one way. Consequently if a sufficiently large number of trials are made on the same boiler under the same conditions, some of the tests will nearly always be found to deviate from the average quite as much as the total possible error here suggested.

If the coal and water deductions are relied on, we know the efficiency and the load. But in view of what has been said it is very doubtful if the regular carefully conducted boiler test burning hand- or stoker-fired coal can be guaranteed to be closer than within plus or minus 3 per cent.

The Heat Balance

The heat balance is often considered as a final check on the correctness of the test. A boiler-test report without a heat balance is just as good as the other kind as far as efficiency at load is concerned. But the heat balance confers dignity and precision on the test report because all the items add up to 100 and this seems to prove the correctness of everything concerned in it. However, since it does not "balance" or rather that we *make* it balance, the term "heat balance" is not without humor. If accountants submitted items in their balance sheets called "unaccounted for" amounting to $5 in every hundred dollars there would be considerable unpleasantness. Of course, a heat balance is different because there is the excuse that no way has been discovered to find out the amounts of some of the items and the others are not as accurate as is generally believed. There is a case of four consecutive tests made on the same boiler by an engineering professor of deserved repute and large boiler-testing experience, in which the "unaccounted for" was respectively 8.7, 0.4, 6.4, and 7.4 per cent. The trials run by Dr. Jacobus on the Delray boilers were among the most careful ever made, and the "unaccounted for" item runs from 1.51 to 4.83—a difference of over 3 per cent. Incidentally, the efficiencies in the series of tests vary over plus or minus 1 per cent from their average rating-efficiency curve.

The real value of a heat balance lies in the presentation of the various losses and their amounts, and therefore it is more a *statement* than a *balance.*

Care has to be taken to get an average sample of flue gas. Its composition sometimes varies greatly across the width of the setting—as much as 5 per cent of CO_2 according to some experiments, though perhaps some of this variation was caused by the quality of the gases changing rapidly between taking samples. It seems likely that if the gas sample is drawn from some point well within the gas flow, it is fairly representative, for if that were not so, the "unaccounted for" would show a still larger variation than it actually does. This also applies to exit gas temperature, where the radiation effect may affect the readings 50 deg. fahr. With care in placing the instruments the error is perhaps within plus or minus 20 deg. fahr., or about plus or minus 1 in the percentage of heat loss to the stack.

Efficiencies

Even the efficiency as now reported does not provide a proper basis for making comparison between different trials under different conditions. An efficiency of 75 per cent with a steam pressure of 225 lb. is a better performance than the same efficiency at 75 lb. pressure. To be serviceable for comparison, the efficiency should be based on what is theoretically possible in each individual case, and this is governed by the temperature of what is being heated and not by the temperature of the atmosphere.

At first sight it appears that it is not theoretically possible to get the exit gas temperature below that of the boiling point. Therefore the efficiency should be based on perfect combustion with the theoretical amount of air and the products of combustion cooled to the boiling point for the existing pressure. This is not very difficult, and the 100 per cent figure would be set for the particular fuel and steam pressure under consideration. The efficiency would be the percentage of the figure attained on the test and might be called the "actual" efficiency to distinguish it from the efficiency as now reported, which might be called the "theoretical" efficiency.

Whether the mean temperature of the water in the boiler or that at the gas exit should be used, is another consideration. In a horizontal water-tube boiler, for instance, the lowest tubes may be 15 ft. below the water level. The added pressure due to this head of water is 6 lb., making a total pressure of 156 lb. when the gage pressure is 150 lb. This increases the boiling point 3 deg., and either the water is hotter at the bottom of the boiler or no steam is made there.

The temperature to be used is really dependent upon the extent to which the cold feedwater is segregated. The boiling point may be considered as the proper temperature to use with a boiler in which the feed is so mixed with the circulation that no cold water comes in contact with the heating surface, while with a separate economizer or a flash boiler the temperature of the feedwater should be adopted. But difficulties at once arise with boilers where there is partial segregation. In boilers having integral economizers the feedwater may be wholly or partly segregated. In integral economizers of the Badenhausen type, for instance, there is considerable circulation within the economizer, and the temperature of the water where the gases leave will certainly be

well above that of the entering water. A somewhat similar condition obtains in the rear bank of the Stirling boiler, which is, or used to be, often called the "economizer bank."

It appears, then, that the design of boiler must be taken into consideration and the temperature chosen be that of the boiling point, or of the cold feedwater, or somewhere between these points according to the extent of segregation of the incoming feed. A chart like Fig. 1 could be used and a position on the curve agreed upon for every type of boiler, such as the following:

POSITION	TYPE OF BOILER
A	Horizontal water-tube
	Scotch marine
	Horizontal return tubular
B	Stirling with rear circulators
C	Stirling without rear circulators
D	Boilers with integral economizers having free circulation
E	Boilers with integral economizers having restricted circulation
F	Boilers with separate economizers
	Flash boilers.

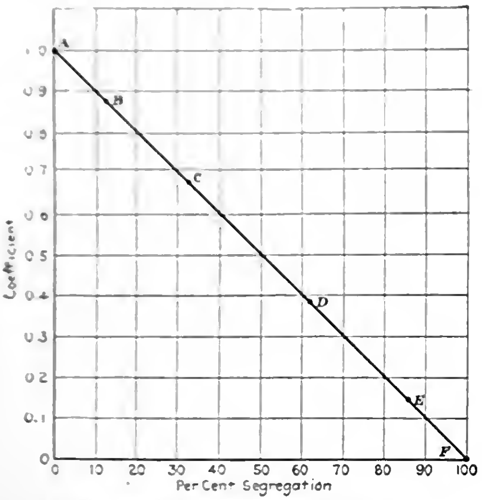

Fig. 1 Effect of Segregation of Feedwater

It is not intended to propose that the positions thus suggested by way of illustration be accepted, either absolutely or relatively. But as an example, with a boiler having 25 per cent segregation, the coefficient as read from the chart is 0.75. Suppose the boiling point is 370 deg. and the feedwater enters at 130 deg., then the difference is 240 deg. and 0.75 of this is 180 deg. Then 180 + 130 = 310 deg. fahr., which is the temperature to be used.

It might be advisable to make some kind of an allowance for the rate of driving, because this would have some effect on the temperature to be used in those boilers having partial segregation of the feedwater.

Probably the simplest way to dispose of the matter is to take the temperature of the water in the boiler at the point where the gases leave, making regular observations during the test. In this way there would be no contention whatever as to the proper temperature to use. The average of these observations would be recorded in the test report.

The efficiency based on the temperature of the water in the boiler is the only efficiency by which different boiler performances may be intelligently compared. But it must be remembered that the limit of temperature on which it is based is artificially imposed. It may be considerably lowered by the installation of an economizer, and perhaps still more so by apparatus yet to be devised or more generally adopted. When an economizer is added it may be that the efficiency—which will now be based on the feedwater temperature—is lower than before. Of course, this is quite proper because this is really the actual efficiency of the apparatus as a heat generator and absorber. But for the comparison of one steam plant with another or for changes in the circumstances of the same plant such as the addition of the economizer, the efficiency based on the heat value of the coal must be used. Therefore it appears highly necessary that both of these efficiencies be reported in every test. These efficiencies may be stated as:

$$\frac{\text{B.t.u. in steam}}{\text{B.t.u. in dry coal}} = \text{Theoretical Boiler and Furnace Efficiency}$$

$$\frac{\text{B.t.u. in steam}}{\text{B.t.u. available}} = \text{Actual Boiler and Furnace Efficiency.}$$

All comparisons of efficiency are properly based on the load in percentage of the boiler rating. When a superheater forms an integral part of the boiler, the heating surface is greatly increased. The efficiency is greater owing to the increased heating surface reducing the temperature of the escaping gases. But still the efficiency is plotted against boiler rating, in other words, against boiler heating surface only. This is wrong. The combination should be rated at some higher horsepower than that of the boiler only. It would be a very difficult matter to decide how much to allow for superheating surface as its heat-transfer rate is quite different from that of boiler heating surface. But superheating surface should be rated as the equivalent of so much boiler heating surface.

The same thing applies to economizers. What is the proper way to report a boiler test where there is an economizer? I quote from a test report case of unquestionable authority:

Water-heating surface	4400 sq. ft.
Builder's rating	440 hp.
Economizer heating surface	6290 sq. ft.
Hp. developed for boiler	1231
Hp. developed for boiler and economizer	1350
Percentage of rating developed for boiler	277
Percentage of rating developed for boiler and economizer	305

What is the meaning of the last item? The one above it is the regular statement of percentage of rating. But the boiler did not develop more horsepower or a higher percentage of rating because there was an economizer near it. The economizer did this extra work—not the boiler. What percentage of the *rating of the economizer* did the economizer develop?

The steam, or its equivalent when electric motors are used, consumed in driving stokers and mechanical-draft apparatus should always be ascertained and reported as a percentage so that it may easily be deducted from the efficiency by any one sufficiently interested. In testing all or most other apparatus, the efficiency is output divided by input; but in boiler testing we do not know yet how to accurately measure the output. We weigh the water going in and boldly state it as output. Surely the available steam sent away from the boiler is the real output, and if so, all steam used to make the boiler and its accessories work should be allowed for. As conscientious engineers we have always strictly seen to it—and shall continue to do so—that such things as internal-combustion engines, hot-air engines and the like shall be tested with a brake so that we know exactly what is their actual output; and the more power they consume in making themselves work, the worse for them. But we seem to prefer to avoid telling any one what the real output of a boiler is.

Economizers raise the efficiency by lowering the flue-gas temperature, and they sometimes do this to a point where the gas temperature is too low to produce sufficient chimney draft, in addition to increasing the draft resistance. So an induced-draft fan is used, but the power taken to drive it is rarely considered.

The following very imposing array of data is sometimes presented:

Water evaporated, actual, per lb. of coal as fired
Water evaporated, actual, per lb. of dry coal
Water evaporated, from and at 212 deg., per lb. of coal as fired
Water evaporated, from and at 212 deg., per lb. of dry coal
Water evaporated, from and at 212 deg., per lb. of combustible.

These items are sometimes carried to one-thousandth of a pound and none of them means anything. Any kind of evaporation per pound of coal in any condition is without meaning unless the heating value of the coal is known, and knowing this the efficiency, which is what is desired, can be easily determined.

In *The Engineer* (London) of February 25, 1921, H. V. Whittaker suggests basing the evaporation on "standard coal" and he further suggests giving this theoretical coal a value of 12,600 B.t.u. If all tests were reported on the basis of this standard coal we would

have a definite standard for the comparison of different performances. But why not go a step further and drop the meaningless evaporation per pound of coal altogether and report the result as B.t.u. in the steam per 100 B.t.u. in the coal? This figure is the efficiency without further ado. There is nothing difficult about it. In calculating the test, the B.t.u. in one pound of liquid is subtracted from the B.t.u. in one pound of steam, superheated or otherwise, and multiplied by the weight of water evaporated. The "factor of evaporation" disappears, and the correction for moisture in the steam is just as easy. The B.t.u. per pound of coal is multiplied by the coal weight and divided into the B.t.u. taken up by the steam. The quotient is readily expressed as B.t.u. in the steam per 100 B.t.u. in the coal. The B.t.u. per hour taken up by the steam is easily converted into the obsolescent "boiler horsepower."

The object of all boiler tests is comparison either with some other test or group of tests or with our general experience, which is the same thing. The report should therefore contain everything which will show the relative arduousness of the conditions under which the test was made, including the variation in load.

Tolerances

In all manufacturing operations it is realized that nothing can be made absolutely correct. Therefore tolerances are allowed. Whether the suggested plus or minus 3 per cent for boiler trials is considered too large or not, the fact remains that the performance of guarantees is demanded without any tolerance whatever. It is said that if guarantees should carry a tolerance of, say, minus 2 per cent, manufacturers would raise their guarantees by 2 per cent, relying on this margin. If all manufacturers followed this policy they would be on an equal footing and no commercial harm would be done. As matters stand now, however, the prudent manufacturer virtually sets his own tolerance by guaranteeing something less than he knows he can accomplish; while if the proposed tolerance is adopted he can guarantee all he knows he can do, and let the tolerance take care of the testing errors.

There is nothing whatever to be gained by reporting efficiency more closely than the nearest tenth of one per cent, or even the nearest half. Not only is such apparent precision as 1 in 1000 unwarranted by the exigencies of boiler testing; but engineering judgment is quite unable to make use of it. It is mentally impossible to differentiate between the relative values of 79.9 and 80.1 per cent efficiency and it seems only sensible to call it 80 per cent. Especially is such overprecision absurd, inasmuch as it is not certain that it was not really 79 or 81 per cent, or even a little further away.

Discussion On Accuracy Of Boiler Tests

The discussion of Mr. Cotton's paper was opened by Grant D. Bradshaw[1] who emphasized the author's contention that unavoidable errors creep into a boiler test which, in the aggregate, amount to a considerable figure if they do not compensate one another. That it is doubtful if the accuracy of a boiler test can be guaranteed closer than within plus or minus 3 per cent, he said, was substantiated by Dr. Jacobus' tests on the Delray boilers, where the unaccounted-for item was from 1.51 to 4.83 per cent. This gives to the figure for radiation and unaccounted-for losses a considerable importance when judging the probable value of results. The problem of sampling steam for the determination of its moisture content, he said, was closely allied in principle to that of collecting a gas sample, where differences in the velocity of gas in the steam and in the collecting tube could not be allowed without error.

Henry Kreisinger[2] wrote that errors in making boiler tests were frequently as large as the author gave them, and in some cases even larger. Only by making several trials of 24 hours or longer at the same rating could dependable results be obtained, he said. He discussed some of the sources of error, such as those in measuring the weight of water evaporated, determination of temperature of superheated steam, the collection and preparation of the coal sample, and gave some comparative figures of coal analyses made at different laboratories from the same sample.

The heat balance, he wrote, if accurately computed, is perhaps the most valuable part of a boiler-test report as it shows what the principle losses are and indicates the accuracy of the test. He agreed with the author in the matter of reporting boiler-test results directly in B.t.u. absorbed per pound of coal, or in B.t.u. absorbed per 100 B.t.u. in the coal, and favored dropping the terms "equivalent evaporation" and "factor of evaporation."

W. A. Carter[3] read a discussion which he had prepared in collaboration with C. F. Hirshfeld,[4] C. Harold Berry[5] and Paul W. Thompson.[6] These engineers made a distinction between commercial and research tests, and thought that the probable errors cited by the author were considerably larger than were justified by experience in reasonably careful commercial testing. Treating tests from the research point of view, they discussed the limitations of accuracy which their experience had taught them to expect. They maintained that overall efficiency as now computed expressed fully the accomplishment of the combination of boiler, furnace and grate, and for strictly commercial testing no other result was desired.

I. E. Moultrop[7] wrote that the degree of reliance which can be safely placed upon the results of a boiler test depends on a knowledge of the conditions under which the test was made, and that the value of the results of the test depends upon the experience of the men who conducted it. He commented on a number of subjects, such as steam sampling, determination of coal consumption, the term "actual efficiency" used by the author, and tolerance.

G. C. Vennum[8] wrote that the heat balance of a boiler test was the best medium for judging the accuracy of the report, and for drawing conclusions as to characteristics of performance. He did not believe that the schedule for reckoning the performance of different boilers under various conditions, as proposed by the author, would offer a good basis for comparison. What was wanted was a knowledge of the relation between the energy in the fuel and the energy available in the steam. Boiler design, feedwater temperature, steam pressure and superheat are all factors in the result, he said, and cannot be adjusted to give a true statement of efficiency.

E. H. Tenney,[9] while agreeing that the possibilities of error in conducting a boiler test are within the limits of accuracy, wrote that the author had not pointed out a method for the elimination of such error. Experience has proved, he said, that a boiler test conducted by reputable engineers, in accordance with the present standards laid down by The American Society of Mechanical Engineers, gives results which can be relied upon and which are accurate for comparison with other trials and conditions. He made a point of the necessity of extending the period of the test over 24 hours, or more, and that a heat balance serves as a check on the reported results.

John E. Bell,[10] in acknowledging the truth of the author's statements about the errors in reporting boiler trials, expressed the opinion that very few boiler tests have been made in this country that are accepted unreservedly. He wrote of the difficulty of sampling coal and of determining a satisfactory analysis and heat value. Importance can be attached only to a long series of tests each of at least 24 hours' duration, checked by duplicate tests, he said, and even such tests are worthless unless every effort has been made to attain the highest efficiency and to eliminate all sources of error. The heat balance is used to determine the importance to attach to such tests. He agreed with the author as to the absurdity of carrying results to an unnecessary number of decimal places.

Economics of Water-Power Development

Discussion of Production, Maintenance and Selling Costs and Fixed Charges—Many Business Hazards and Sometimes Enormous Unrecoverable Losses

By CURTIS A. MEES,[1] CHARLOTTE, N. C.

ECONOMICS as applied to this particular subject relates to the planning and administration of hydroelectric plants in a manner such as to avoid wastefulness and extravagance.

The question of water-power development as a paying proposition, however, is another matter, and since each of these concepts covers a very wide field, it seems preferable at this time to touch, in a very general way only, on the essential factors pertaining to both problems in such a manner as to elicit profitable discussion thereon.

Only in very rare instances is it practicable to depend on water alone for the production of power for commercial purposes, and auxiliary power sources are therefore presumed to be a necessity and their construction and operation is herein considered as concomitant to water-power development.

The power business is akin to that of manufacture, as this term is usually conceived, and the conduct of this business is in many respects successful or unsuccessful in that measure in which the precepts for efficient and profitable manufacture are observed.

In other respects special problems are presented because the product after manufacture must be sold and delivered to the consumer, for instantaneous use in a circumscribed market; and while the selling cost is dependent entirely on the immediate operation of the law of supply and demand, the selling price is generally fixed by regulation.

Just as this is true of any manufacturing enterprise, the success of a power development depends not alone on the perfection of the Physical Structure, i.e., the mechanical equipment, and the Production Structure represented by the operating personnel, but in even greater measure on the efficient functioning of the Commercial Structure and the adequacy and flexibility of the Financial Structure. Many monumental developments are, by the well informed, known to be failures.

It should be readily appreciated, therefore, that in any abstract discussion such as this it is impracticable to attempt anything beyond merely setting forth various items that particularly require consideration in an analysis of the commercial features of a power development, and pointing out in general terms their effect on net earnings, or the margin between selling cost and selling price.

Factors of Selling Costs

Selling cost is made up of raw-material cost, fabrication cost and delivery cost. In each of these costs we have both variable elements subject to fluctuation with quantity production and susceptible to modification, and fixed elements which are not affected by applied economics, once the physical structure has been completed.

To each of these classified accounts there must of course be disbursed, either directly or in proper proportion, managerial supervision, clerical expense, cost of tests and experimental research, and a multiplicity of similar charges which occur in all manufacturing business and involve no peculiar features.

The raw-material cost may be determined by any or all of the following items: rental of water; land and water rights for reservoir; conditioning of reservoir; hydraulic control works; fuel delivered to plant; fuel-handling and storage facilities.

In establishing the feasibility of a development in view of these items, it should be noted that the unit cost of fuel is indeterminate unless quality is fixed by specification. The cost of fuel itself fluctuates with the market, generally in such a manner as to affect all competitors alike. Loss or deterioration in storage is a variable applying equally to fuel or water in a reservoir, and for water as well as fuel the unit cost is indeterminate unless quality and quantity are fixed by specification.

The cost of overflowed lands determines a fixed charge but the useful volume of water available and the effective head at which it may be used are variables, the proper determination of which constitutes the most difficult task involved in power-plant engineering and without the determination of which no unit is established for distribution of the cost.

Curiously enough, the requirements, of purchasers of the product of this factory have a decided influence on the unit cost of the raw material, because while water may momentarily be available, its non-use at that particular moment may result in its utter loss. Prevention of such loss, to the greatest possible extent, is of course an extremely important consideration in the planning of details of the development.

The cost of structures such as dams, gates, pipe lines, coal crushers, oil tanks, etc., determines fixed charges for water or fuel. Operation and maintenance of these structures are variables, and in planning them the engineer may choose whether fixed charges or the variables shall be increased or decreased. For instance, on the one hand a reservoir may be carefully cleared and the expense of so doing becomes a capital cost, or on the other hand only little clearing may be done and floating débris must then be removed from the racks from time to time. This expense then becomes an operating cost.

Fabrication Cost

Of the three cost elements, fabrication is least affected by fortuitous circumstances. In a broad sense this cost is made up of fixed charges growing out of the capital cost of erected power-generating equipment, suitably provided with necessary or desirable adjuncts, housed or located outdoors as the case might be, and of operating charges which include wages, supplies, repair parts, etc. Capital cost of the plant may, however, and quite properly so, lie between wide limits for the same output of product, depending on two totally distinct provisions: uniformity of stream flow and character of service requirements, both as to continuity and uniformity.

It must be borne in mind that the manufactured product is kilowatt-hours, that the time element is just as important as the capacity element and that, in general, a sale is consummated only when capacity is available at the instant of use and for the period of use. Thus the hours of use for any given market must be most carefully predetermined for the proper selection of prime movers, and beyond this capacity must also be provided equivalent to the maximum instantaneous demand for current, else the product will not be salable.

It is readily apparent, therefore, that, in general, only one-half as much generating equipment is necessary for a 24-hour load as for a 12-hour load and that for a 24-hour load only one-half as much equipment is required to produce a perfectly uniform output as for a demand which fluctuates from zero to double the average load.

Capacity for the water-power plant having been fixed by the character of the load, there follows the determination of proper capacity for the auxiliary plant.

While this choice may possibly be dependent on a volume of output imperatively continuous, it is much more likely that it will hinge on meteorological criteria. One need only to mention that, in the first place, the run-off from any drainage area or the discharge of a stream fluctuates between very small quantities at times of drought and quantities sometimes many thousand times greater when in flood with, in general, little regularity about the occurence of either stage, and that, in the second place, the average usable discharge for some years is considerably lower than for others.

Natural stream flow is determined either by measured discharge or by computed run-off based on recorded rainfall. From these data there is estimated the average annual stream flow and these determinations will approach correct values according to the length

---

[1] Mees & Mees. Mem. Am.Soc.M.E.

Presented at the Spring Meeting, Atlanta, Ga., May 8 to 11, 1922, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. All papers are subject to revision.

of the period of observations considered. These findings should be modified by an accuracy factor.

Depending on the topography of the development site, either at the power plant or on the drainage area above it, storage capacity may be created of such extent as to afford either daily or seasonal regulation. By daily or weekly regulation is meant the conservation of natural stream flow during either 24 hours or 7 days for use during those hours only when load can be sold. By seasonal regulation is meant the controlled, artificial increase of natural stream flow out of waters stored during periods of run-off in excess of the usable quantity.

Regulated stream flow having been estimated for each year and for the average of all years of record, it will be found that, when daily discharges are plotted as shown on Fig. 1, one can very readily forecast what power output is continuous and what additional output may be sold for any predetermined portion of the year, as this is fixed by low-water stages.

For high-water stages, while there will be an excess of water available, it frequently happens that loss of head results from this cause and in that event restriction of output must be determined similarly as for low-water stages.

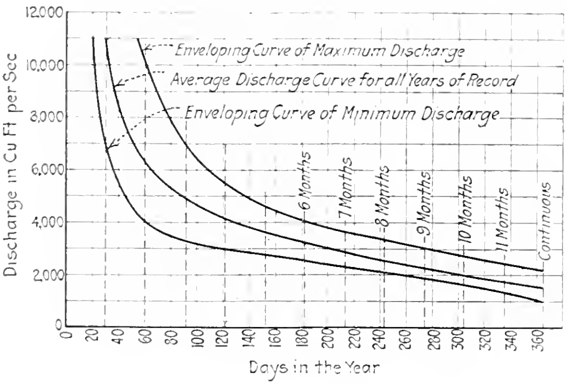

Fig. 1 Stream Flow During Various Portions of the Year

Only in exceptional cases is it commercially practicable to develop a water-power plant for an output based on absolute minimum stream flow, and it is therefore customary to base earnings on that output which may be produced in the average year.

The equipment of the auxiliary plant is then primarily fixed by that capacity which may be necessary to supplement the water output of the lowest year to bring it up to that of the average year. Beyond this, except for possible emergency capacity, it becomes a question of dollars and cents, based on salability of secondary power and rates which may be secured for this service, as to the extent to which one can afford to install auxiliary equipment for the conversion of short-term water output into continuous combined water and auxiliary output.

Dependent on local conditions, the capacity which must be installed for emergency service might finally be the determining factor in equipment selection. It may happen that in flood a water-power plant may be completely incapacitated through loss of head so great as to make impossible the maintenance of synchronous speed. Ice blocks also might completely prevent operation of a plant. For such cases, under certain load conditions it might become imperative to provide 100 per cent stand-by capacity.

Legitimate capital cost and resulting fixed charges must therefore be most carefully determined for each individual project and comparative figures are not necessarily indicative of their propriety.

Another so-called fixed charge is quite beyond control and that is taxes. Cost of supplies and repair parts are regulated by the law of supply and demand and cost of labor may or may not be determined similarly according to the extent to which organized labor can enforce its dicta as to rules and rates.

One phase of control as to fabrication cost is of particular importance in this business and that is the continuous, most efficient conversion of raw material into the finished product. This is not a question of workmanship but rather one of intelligent direction. Loss in kilowatt-hours produced out of available water and per unit of fuel may, under improper allocation of part loads to various equipment items, be considerable and difficult of detection.

Delivery Cost

Delivery of power may be effected either direct to the ultimate consumer or at wholesale to a distributor and the cost of delivery depends very largely on the method in vogue or proposed, but the greater cost of retail service is offset by a rate differential such that in the end earnings on the unit of investment are not, in general, materially affected by the adoption of one rather than the other of these plans.

A transmission system may be considered to be composed of trunk lines, secondary lines and feeders. The cost of trunk lines depends primarily on the proximity of the power plants, principal and auxiliary, to each other and to the center of load, whereas the cost of secondary lines and feeders depends largely on quantity requirements, both as to capacity and period of use, or what is synonymous, the number of consumers served and the density of the market.

Secondarily the cost of transmission lines is affected by the relative importance of assured continuity of service and in addition the locality variable enters into the problem. Urban work, values of land, size of properties crossed and similar circumstances greatly affect the cost of lines. The rigors of climate, cyclones and the prevalence of electrical disturbance require careful consideration and arbitrary regulations as to structural details must frequently be observed whether the cost is justified or not.

Conductor cost should be balanced for permissible line loss at prevailing rates, and transformers, to prevent excessive core losses, should be so proportioned as to carry capacity loading as much as possible.

Fixed charges for distribution plant, based on right-of-way costs, leases or fees and equipment and structures costs may therefore also vary between very wide limits with perfect propriety.

Operating costs of the system depend on topography, multiplicity of lines, substations and terminals and their accessibility by rail or highway, weather conditions and special maintenance requirements for city lines, stream or railroad crossings.

Factors of Selling Price

Selling price depends on either the cost of a competitive product or rates fixed by a regulatory body; i.e., in the last analysis, by the purchaser.

The competitive product may be either purchased electrical power or produced power. Regarding the practicability of competition with purchased power, there can of course be no controversy. However, the feasibility of building a water-power plant or system for the competitive sale of electricity with that otherwise produced is not always so readily established. The selling cost of high-load-factor power, produced in large volumes with fuel at reasonable cost, is not, in general, appreciably higher than that produced by water, if in the latter case the transmission cost amounts to much.

In small fuel plants, however, and particularly when operating at a low load factor, it is at the present time impossible to produce power at a cost as low as that at which reasonably near and economically developed water power can be delivered.

But the efficiency of water-power-plant equipment and the overall efficiency of water-power production are already very high and only little improvement can ever be effected, while the efficiency with which fuel power is produced, both as to fuel transportation and conversion, is exceedingly low and great improvement may confidently be expected. Hence the present margin between selling costs of power produced by these several methods is not so great but that a pronounced improvement in the effective use of fuel may, in a great measure, jeopardize the investments made in water-power plants.

Effect of Regulation

To regulation we owe general recognition as public utilities and as such we are granted eminent domain for transmission-line rights of way, and sometimes for water rights. This means that we cannot be arbitrarily stopped from proceeding with certain plans

of development and that we do not have to pay very much more for property rights and easements than the market value thereof.

The impression prevails that, under regulation, the income of a utility is guaranteed. This is an utter fallacy. The income is merely limited, and in too many cases unfairly limited. Within the last few years earnings on securities have in too many instances had to be paid out of funds which should properly have been devoted to maintenance, or possibly unwise curtailments have had to be made in personnel. Deferred maintenance is the most serious disease with which a utility may be afflicted.

Theoretically, regulation is not so bad because, to that extent to which it is insisted that a high standard of service shall be maintained without discrimination as to rates, it benefits those who conscientiously administer this industry. This, however, is practice or service regulation and not rate regulation. Where competition is free, economic law operates to prevent continued exorbitant profit taking, the art is developed, and progress is made. Particularly with the power industry would this be the case.

Bearing on this question, the following issues are important:

Permitted rates of return on investment are inadequate
Certain otherwise irretrievable losses of income may not be covered by rates
Certain non-insurable risks may not be offset out of rates
Unfair competition is not throttled
Efficiency receives no reward.

A public utility that is not constantly expanding is decadent. New money must at frequent intervals be secured to finance extensions required from time to time, oftentimes under instructions of the commissioners.

In principle the returns on investment permitted under regulation are intended to be sufficient only for payment of interest and dividend, and for the perpetuation of the investment out of a depreciation reserve. The establishment of a sinking fund, out of earnings, is not proposed and borrowed money must therefore be kept in perpetuity.

It is of course both logical and proper that the depreciation reserve fund should be reinvested in the property to cover cost of extensions, but this money should in the first place, under healthy growth, be inadequate, and furthermore, once so invested the resources of the corporation become so non-liquid as to expose the administration to considerable financial embarrassment in cases of emergency when immediate funds should be available. At such times the desperate need for money is naturally and not without warrant taken advantage of because credit has been impaired.

Composition of Financial Structure

The financial structure which supports this industry is, in general, composed of:

A Lender: To whom payment of interest is compulsory under the security which he holds and which amounts to the entire property owned.

The lender sees to it that this is a safe risk. His criterion generally is that estimated net earnings shall be at least two times and generally two and one-half times the bond interest.

A Preferred Investor: In stock whose payment in dividends is substantially guaranteed under a lien subordinate only to the bondholders' equity. This investment is attended with all sorts of management and non-insurable structural risks.

A Speculative Investor: In common stock whose dividends are paid only if there is anything left over.

Customary and proper rates of return under respective security holdings may be set up as follows, based on the existing actual, not legal, interest rate for short-term collateral loans of equal volume:

	Per Cent				
Actual interest rate..	4	5	6	7	8
Bond interest.............	5	6	7	8	9
Preferred-stock dividend ...	7	8	9	10	11
Common-stock dividend....	10	$11^{1}/_{2}$	13	$14^{1}/_{2}$	16

One court held that the average rate of return on the entire investment should be three per cent above the existing interest rate.

The actual rate of return on capital ordinarily invested in any business enterprise is oftentimes lost sight of because it is confounded with the percentage of net profits made on units of output. If a turnover can be made four times in a year and a net profit of 6 per cent is made each time on the goods sold, the actual rate of return is 24 per cent and not 6 per cent. This is not at all an extraordinary performance.

A power plant is exceedingly fortunate if it makes a turnover once in four or five years. Returns permitted under regulation lie between 6 and 8 per cent. Some commissions may possibly, but not to our knowledge, allow more.

An ideal organization is one-third each of bonds, preferred and common stock and, with brokerage included as a capital cost, net earnings should be permitted as follows, as based on actual interest rates: 4 per cent and $7^{1}/_{3}$ per cent; 5 per cent and 8.5 per cent; 6 per cent and $9^{2}/_{3}$ per cent; 7 per cent and $10^{5}/_{6}$ per cent; 8 per cent and 12 per cent.

When commissions arbitrarily fix a rate of return which is not in keeping with financial conditions, money must be secured from such sources and at rates such that interest payments will remain within earnings. The result of non-observance of these fundamentals has been that utilities have been compelled to mortgage too large a part of their equities, bonded indebtedness has become dangerously great, and no new funds are available. Today permissible earnings are, in general, insufficient to attract new capital.

Unrecoverable Losses

Based on the law that utilities should not make unjust profits, it should equitably follow that they are entitled to protection against unjust losses. In financing such undertakings reliance is placed on constancy of return and rates are predicated on probable normal output. Industrial activity, however, varies in cycles and a falling off of normal business cuts into earnings in a manner which cannot be guarded against because, in general, equipment capacity kept in readiness to serve under contract provisions cannot be otherwise put to work. Contract minima, ordinarily, assure nothing more than the earning of bond interest alone.

Losses of output and therefore earnings are sometimes seriously affected by storm or flood conditions, against which the property cannot be guarded. Fire and breakdowns may, without fault on the part of the operating personnel, render normal service impossible and emergency service under any of these conditions is apt to be very expensive, but nevertheless practically obligatory. Interference with business by strikes, declaration of martial law, etc., mean unavoidable loss of income.

Against none of these contingencies can the management protect itself as this is customarily done and essential to safe business conduct, i.e., by the setting aside of a contingency or, as it has been called, a "stabilization," fund.

As to water power particularly, a development condition prevails which must be taken into account. The cost of prime movers is almost invariably only a small percentage of the total cost of all structures which must be completed in order to be able to manufacture any power whatever and the progressive development of the plant to meet the growing requirements of the market is more or less impracticable. Overdevelopment, therefore, is the rule, and since, for purposes of rate fixing, earnings are predicated on possible output instead of on probable demand, certain losses of income occur during the period required to bring sales up to the developed output capacity.

Under these unalterable circumstances the loss of earnings which are necessary to offset interest and dividend payments and the setting aside of funds to cover a depreciation which is actually going on, may legitimately be treated as development costs, either to be included in the capital cost on which the rate of return is based, or otherwise covered in the rate composition. One court, however, has held that any compensation for business losses in the adjustment of rates leads to a "reductio ad absurdum."

Quite enormous losses have been incurred by power companies due to great delay in the granting of those higher rates which the commissions by their own rulings have established as having been justified. Such requests of course grew very largely out of increased operating costs and to that extent to which they represent operating costs only and not the earnings of capital invested during the period of high prices, a future reduction in rates is to be expected. It remains to be seen whether it will be permitted that losses already sustained can be recouped before reductions in rates are ordered.

Floods may destroy dams and cause tremendous damage to persons and property. Lightning may burn up transformers and other equipment. Falling trees, wind or sleet storms may cut transmission lines in two and by short-circuit magnify the direct damage. Death-dealing currents take their toll of life regardless of even extraordinary precautions and, while such a risk is insurable, the amounts involved are limited and in any event defense in litigation is very costly.

Premature destruction of structures and equipment is not covered by the depreciation reserve and accidents requiring the outlay of additional capital without a corresponding increase in earning capacity can be covered only by a contingency reserve, provision for the accumulation of which should be included in the rate structure.

The antiquation or obsolescence of parts or even the whole of the plant through the possible development of novel equipment or methods for power production at lower selling cost than that possible with equipment now available or even by water power at all, is not too remote a happening to be given consideration, and this contingency should, in a measure at least, be offset by liberal present earnings.

That efficiently operating public utilities promote the welfare and growth of any community is obvious. If, therefore, the regulatory bodies would take a proper pride in the efficiency of the utilities which they regulate and would do everything to make it possible for the companies to deliver on sound financial bases the best service at the lowest rate, they would be doing their communities a signal service. Also in order to allay much of the antagonism toward public utilities fostered by political attacks, regulatory bodies should demand of all utilities under their jurisdiction, including the municipal plants, a uniform system of accounting such as to expose many of the fallacies now entertained.

Rates for electrical current are presumably based on cost of the service, painstakingly predetermined for each particular case. Cost of service is, however, susceptible to considerable modification depending on the degree of efficiency attained in administration of the property. If earnings are absolutely limited, the incentive to efficiency is lost and that is one of the most discouraging features of rate regulation. Zealous communism is only a theory.

Having in broad terms indicated some of the more vexing problems that confront the industry, an attempt will now be made to present as concisely as possible a schedule of economic considerations, the observance of which may lead to more satisfactory solution of these problems.

As to the Physical Structure

Design and Construction of Plant:

1 *Thorough Preliminary Study:* Geologically, meteorologically, legally and commercially. Such study requires time and money and both are too often curtailed.

2 *Control of Entire Stream:* To make regulation most effective and to prevent competitive injury.

3 *Degree of Stream-Flow Utilization:* The extent to which secondary power may be developed for sale or conversion into primary power.

4 *Best Use of Land or Water Rights:* Mechanical or automatic pond-level control to maintain a maximum head.

5 *Plan of Development or General Layout:* Location, utilization of site, (extent, method) progressive construction and stream regulation, location of auxiliaries, territorial control of market.

6 *Type of Structures or Detail Layout:* Kinds of dams, character of water channels, equipment setting, equipment housing, effective design for tail race, use of adjunct equipment, and belt-transmission trunk lines.

7 *Type of Equipment:* Prime movers suitable for characteristic load and service. Effective accessories. Adequate recording instruments, High-efficiency draft tubes and use of ejectors or tail-water elevation control. Air coolers for generators. High-potential generation or transmission. Automatic or semi-automatic generating stations and substations.

Selection of Auxiliary Equipment. Ordinarily this should be high-capacity, quick-response, equipment of low first cost. Dependability is much more important than economy of operation, although low attendance costs are to be attained if possible. For this purpose there are best adapted steam turbines and boilers equipped with mechanically atomizing oil burners or powdered-coal-burning equipment. Heat balance is of secondary importance. Electrically operated auxiliaries are better for quick starting.

8 *Capacity of Equipment, Unit and Total:* Adaptability for characteristic load changes. Maintenance of balance, large and small units. Amplitude of reserve capacity. The cost of prime movers alone is generally only a small proportion of the total development cost and sufficient spare capacity should be installed.

9 *Economical Construction:* Effective building organization, executive, clerical, supervisory. Conscientious inspection. Economical purchasing. Reduction of unproductive construction period to the economical minimum. Assurance of service continuity by careful testing out.

10 Interconnection between power systems.

As to the Production Structure

Operation of Plant—Production and Distribution:

Routine:

1 Regular inspection and tests; owner's installation and customer's installation.

2 Effective service records and accounting.

3 Proper use, maintenance and loading of equipment.

4 Maintenance of balance between water and auxiliary power. Assuming storage to exist, it is generally best when an auxiliary plant requires operation, to operate it at full load, taking peaks on the water-power plant.

5 Fuel-efficiency control. Volume purchase by combined interests on specification basis under strict supervision.

6 Perfect load dispatching based on meteorological observations.

Administrative:

1 Proper selection of employees.

2 Education and training of employees—general, specific. Explicit written instructions should be furnished each employee setting forth his duties, methods of accomplishment and reasons for performance. Maintenance of discipline.

3 Development of loyalty and coöperation in employees. This may be brought about by fair dealing, manifest integrity of purpose, welfare work, encouragement by public recognition of especially meritorious service, appreciative adoption of suggestions and partnership in the business which should be made easy.

4 Acquirement of expert detail knowledge of the business in a manner to make information instantly available for effective analysis and synthesis.

5 Research and investigation to perfect methods which information should be coöperatively interchanged.

As to the Commercial Structure

Selling the Service:

1 Perfection of service.

2 Saturation of system; development of rural loads.

3 Selection of load. While the service requirements in a given market are quite characteristic, some improvement is generally possible. The diversity factor may be improved, the maximum demand may be cut down and the load factor may be raised by the encouragement of off-peak loading. Electrolytic processes, electrical industrial heating, domestic use of heat in all manner of appliances, and off-peak pumping and similar intermittent service suggest themselves as desirable loads.

4 Protective contract provisions: Service classifications, unavoidable interruptions of service not to be penalized, maximum demand limitations, power-factor penalties and bonus, fuel clauses, agreement to pass along extraordinary taxes, cost-of-living adjustment.

5 Classified service accounting to detect inadequacy of certain rates.

6 Development of a sympathetic, understanding attitude in consumer by intelligent publicity and helpful advice as to proper use of current and equipment.

7 Avoidance of too preponderant a load from either one or just a few consumers or either one or several closely allied industries.

As to the Financial Structure

Providing Funds:

1 Balance in equities of classified security holders.

2 Adequate working capital provisions.

3 Bond issue under a series mortgage.

4 Consumer partnership.

5 Reinvestment of depreciation reserve.

In all of the above it must be remembered that small plants require different treatment from that accorded to big plants and that isolated plants must be quite differently planned from those forming part of a chain or system.

In the light of what has gone before the question as to whether water-power development is a paying proposition may now more intelligently be answered.

Water-power development *does* pay—never big, however, but even very small plants of high unit cost entirely justify their existence. It *does not* pay at this time because the public will not invest in securities at interest or dividend rates which permit the financing of such undertakings on a basis of present permissible earnings.

However, these facts notwithstanding it is a gloriously constructive work and, because of the individuality of each project and the ever present hazard, it certainly may be ranked as the greatest sport on earth.

Heat Losses from Bare and Covered W. I. Pipe at Temperatures up to 800 Deg. Fahr.

By R. H. HEILMAN,[1] PITTSBURGH, PA.

High-temperature superheated steam running up to 800 deg. fahr. and high-temperature chemical processes are being more and more widely used, and accordingly the question of heat losses from pipes under such temperature conditions is one of importance to the engineering profession.

This paper presents the findings of an experimental investigation conducted in the Mellon Institute of Industrial Research of the University of Pittsburgh. The losses from bare wrought-iron pipes have been measured for temperatures up to and including 800 deg. fahr. They have been studied carefully for pipes of various diameters, and empirical formulas are presented whereby the loss from insulated pipes of any diameter may be readily calculated.

MANUFACTURERS of pipe coverings often are required to guarantee that the application of a specified heat-insulating covering will effect a certain percentage saving of the heat which would be lost entirely from a bare pipe. Since the bare-pipe loss is the 100 per cent value against which the losses from the covered pipe must be compared, it is essential that the loss from the bare pipe shall be known accurately.

Many investigators have studied the heat losses from bare pipes. Perhaps the most noteworthy of those experimentalists was the French physicist Péclet. Owing, however, to the fact that Péclet's experiments were conducted at very low temperatures, while subsequent investigators confined themselves mostly to one pipe size only, the Mellon Institute deemed it advisable to carry on the research to much higher temperatures and on 1-in., 3-in., and 10-in. pipe.

[1] In this table coal has been figured at $4.00 per ton of 2000 lb., 13,000 B.t.u. per lb. of coal; labor, boiler-room expense, etc., taken at $1.00 per ton, making total value of coal fired at $5.00 per ton. Boiler efficiency taken at 70 per cent; air temp. 70 deg. fahr. Experimental data obtained at the Mellon Institute.

The 1-in. pipe was selected for test at the higher temperatures, as the relatively small amount of heat loss from a 1-in. pipe could not greatly affect the room temperature. This pipe was run up to a temperature of 800 deg. fahr. The average room temperature throughout this test was 81 deg. fahr. and the temperature did not vary more than 1.8 deg. fahr. during its progress.

The locations of the curves for the 3-in. and the 10-in. pipes were obtained by experiment at the lower temperatures, as indicated by the solid lines in Fig. 1. The values for the higher temperatures are the result of extending the curves parallel to the curve obtained for the 1-in. pipe. This procedure was necessary because of the fact that the larger pipes could not be raised to the higher temperatures without raising considerably the temperature of the room.

In Table 1 the loss in dollars and cents and in pounds of coal per 100 lineal feet of horizontal bare iron is tabulated for temperatures up to 664 deg. fahr. The loss varies from $1.32 for 100 lineal feet of ½-in. pipe at 180 deg. fahr. to $297.50 for 100 lineal feet of 18-in. pipe at 664 deg. fahr.

THEORY OF HEAT LOSS FROM INSULATED PIPES

In order to calculate the loss of heat from an insulated pipe or boiler, it is necessary to know the total temperature drop from the pipe to the surrounding air; and to enable one to make accurate calculations it is required that the component temperature drops be known.

The total temperature drop from the steam inside a pipe to the outer air can be considered as made up of four components, as follows:

a Drop from steam to the outer surface of the pipe
b Drop from outside surface of the pipe to inside surface of the insulation
c Drop from the inside surface of the insulation to the outside surface of the insulation
d Drop from outside surface of the insulation to the surrounding air.

---

[1] Industrial Fellow, Mellon Institute. Jun. Mem. Am.Soc.M.E.

Abridgment of paper presented at the Spring Meeting, Atlanta, Ga., May 8 to 11, 1922, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. All papers are subject to revision.

The temperature drop from the steam to the outer surface of the pipe depends upon the resistance to heat flow offered by the film at the inner surface and the resistance offered by the iron wall of the pipe. No attempt was made to measure this temperature drop in the present investigation, as it was considered to be so small as to be negligible.

The temperature drop from the outer surface of the pipe to the inner surface of the covering for 1-in., 3-in., and 10-in. pipe is shown in Fig. 2. These curves show that the temperature drop increases as the pipe diameter decreases. A test was also made on a 3-in. pipe with an air space of 1.2 in. between the surface of the pipe and the insulation. By comparing this curve with the curve for an air space of 0.1 in., it is observed that the temperature drop for a 1.2-in. air space is only a few degrees more than for an air space of 0.1 in. This is probably due to the fact that for air spaces much greater than 0.2 in. convection currents are increased, thus causing an increase in heat loss. An examination of Fig. 2 shows that the temperature drop for a 0.1-in air space is approximately equal to that for 0.1 in. of commercial insulations, so that this temperature drop can be neglected in calculations and the pipe covering considered as fitting close to the pipe with the pipe temperature and the temperature at the outer surface of the covering as the temperatures bounding the covering.

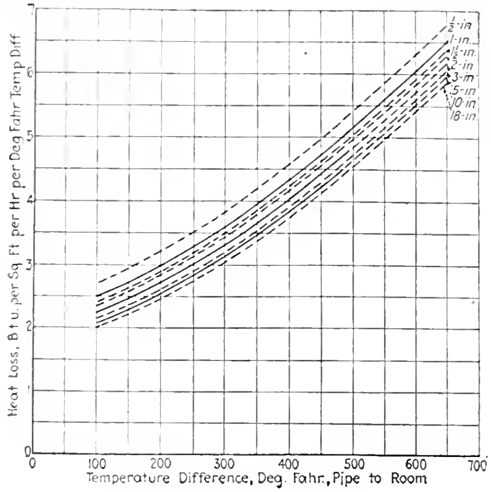

Fig. 1 Bare-Pipe Loss Curves

The drop in temperature, or the temperature-gradient curve through the insulation, depends upon the thickness of the covering and the curvature. In a cylindrical covering the resistance to heat flow diminishes as the outer surface is approached, the temperature drop becomes less, and the gradient curve is bowed downward if the curvature alone is taken into consideration. However, the absolute conductivity decreases as the outer surface is neared, with a consequent bowing up of the gradient curve, and the two tend to counteract each other, so that the temperature-gradient curve may be bowed either up or down or be a straight line, depending upon the curvature of the cylinder. The temperature-gradient curve for a flat surface should bow up.

It is highly desirable that tests should be conducted on commercial steam-pipe coverings of different thicknesses and at different temperatures, in order to obtain mean absolute-conductivity curves for the different thicknesses.

The temperature drop from the outer surface of the insulation to the surrounding air depends upon the amount of heat emitted by radiation and air contact. This in turn is dependent upon the nature of the surface of the body, the shape of the body, the excess of its temperature over that of objects to which radiation takes place, and the absolute value of the temperature of these bodies. Commercial steam-pipe coverings are invariably covered with a canvas jacket. From the above-mentioned facts it is obvious that the loss from a canvas surface at a given temperature is independent of what is under the canvas, so that, if the canvas-loss law can be ascertained, this law may be applied to the loss from steam-pipe coverings and thus the temperature of the outer surface of the insulation, can be determined. In making calculations of heat loss through an insulation, it is absolutely necessary to know the temperatures at the inner and outer surfaces.

Péclet made a careful study of the heat emissivity from various surfaces, canvas surfaces included. As mentioned, however, his experiments were conducted at relatively low temperatures. McMillan[1] made a study of the heat emissivity from a canvas surface in his study of commercial steam-pipe coverings, but confined his experiments to one pipe size only. Nevertheless, McMillan's results in the form of a curve present a readier means of calculating the losses from steam-pipe coverings than do Péclet's, whose observations, while taking all the variables into consideration, are in too complicated a form to provide a ready means of calculation.

Since McMillan's canvas-surface-loss curve was obtained from experiments on one pipe size only, this curve can be used in making calculations on coverings of a diameter approximately the diameter of the coverings tested. In order to be able to calculate the loss of heat from pipe coverings of any diameter, it has been necessary to obtain the canvas-surface-loss curves for various diameters. Accordingly, coverings were tested on the 1-in., 3-in., and 10-in. pipes used in determining the bare-pipe losses. The average outer diameters of the coverings used were 3.1 in., 9.5 in. and 17.2 in. The results of these tests are shown in Fig. 3.

In order to simplify the calculations necessary to determine the loss of heat through coverings of various diameters, an equation for the three curves shown in Fig. 3 has been derived. In this equation

$$T_d = \frac{272.5\,h}{h + \dfrac{564}{D^{0.19}}} \qquad [1]$$

T_d = temperature difference between canvas surface and room, deg. fahr.
h = total B.t.u. loss per hour per square foot of canvas surface
D = outer surface diameter, inches.

This equation is approximately accurate for diameters up to 2 ft.

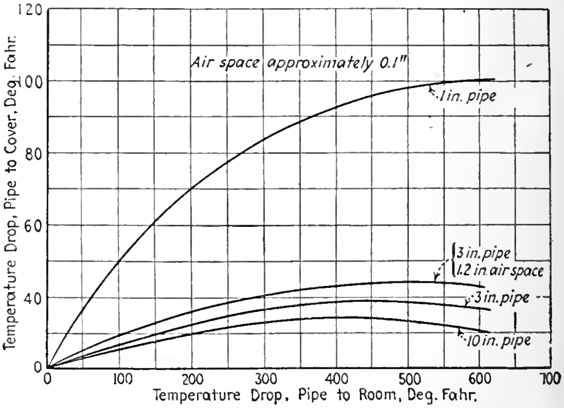

Fig. 2 Temperature Drop from Outer Surface of Pipe to Inner Surface of Covering

Thermocouples were used in determining the canvas temperatures. During this investigation it was found that the couple when just inserted under the canvas, would invariably read low. This difficulty was overcome by inserting it under the canvas for a distance of several inches, this distance depending upon the size of the couple and the temperature of the covering.

Sample Calculations

A covering 2 in. thick, having a mean absolute-conductivity coefficient of 0.56, is placed on a 4½-in. outside-diameter pipe maintained at a temperature of 400 deg. fahr. The temperature of the surrounding air is 700 deg. fahr. Determine the heat flow H in B.t.u. per hour per sq. ft. of pipe surface.

---

[1] Trans. Am.Soc.M.E., vol. 37, p. 928.

The heat flow through a cylinder is given by the following equation:

$$h = \frac{K(T_1 - T_2)}{r_1 \log_e \frac{r_2}{r_1}} \quad \ldots\ldots\ldots\ldots [2]$$

where T_2 is the temperature at the outer surface of the covering. To obtain T_2, knowing only T_1, the pipe temperature and T_3, the room temperature, it is necessary to change the form of the equation so as to include T_4, thus:

$$h = \frac{K(T_1 - T_3 - T_4)}{r_2 \log_e \frac{r_2}{r_1}} \quad \ldots\ldots [3]$$

in which

K = mean absolute conductivity of insulation
r_1 = radius of inner surface of insulation, inches
r_2 = radius of outer surface of insulation, in inches
T_4 = value given by Equation [1].

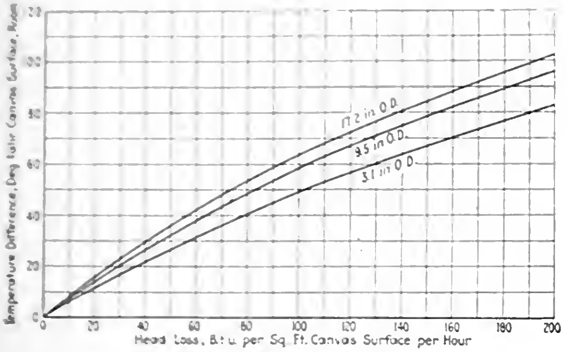

Fig. 3 Canvas-Surface Loss-Curves

Substituting in [3], there results

$$h = 0.56 \left[\frac{400 - 70 - \dfrac{272.5\,h}{h + \dfrac{564}{8.5^{01.9}}}}{4.25 \log_e \dfrac{4.25}{2.25}} \right]$$

$$= 0.207 \left(330 - \frac{272.5\,h}{h + 375}\right)$$

$$= \frac{-\sqrt{363.1 \pm 363.1^2 + 4 \times 25{,}600}}{2} = 60.4$$

whence $H = 60.4 \times \dfrac{4.25}{2.25} = 114$ B.t.u. loss per sq. ft. of pipe surface.

The temperature of the outer surface of the covering can be obtained by substituting the value of h in the equation $T_4 = 272.5\,h/(h + 375)$, reducing to $T_4 = 37.6$. Therefore the temperature of the outer surface of the covering is

$$37.6 + 70 = 107.6 \text{ deg. fahr.}$$

Discussion

In discussing Mr. Heilman's paper, L. L. Barrett[1] wrote that the author's statement that a 0.1-in. air space between the pipe and insulation increased the overall loss was not apparently borne out by the further statement that the temperature drop for a 0.1-in. air space was approximately equal to that of 0.1 in. of insulation. It was unfortunate, he wrote, that the impression was given that conductivity was related to the curvature of the covering. Conductivity was a specific property of the material, independent of shape. He wrote at length on the theory of heat loss from pipes, and the relation between conductivity and temperature.

L. B. McMillan[1] wrote that it was interesting to note that the author's results on losses from various sizes of bare pipes showed smaller differences between large and small pipes than those given by Paulding. He was of the opinion that the author's curves were more nearly correct than Paulding's. He pointed out that temperature drop depended not only on resistance of the air space but also on the amount of heat flowing across the air space and out from the insulation. He also called attention to the apparently contradictory statement regarding the 0.1-in. air space, and to the fact that the absolute conductivity was a specific property of the material and was independent of its shape or size.

B. N. Broido[2] called attention to the property of superheated steam of not readily giving up its heat, and said that, although this was less evident in covered than in bare pipe, it still was an important property to take advantage of in power plants because no covering could be a perfect insulator. In the table of losses from bare-iron steam pipes, he said, the author made the same error as many of the pipe-covering manufacturers in giving the pounds of pressure of the steam and the superheat in degrees fahrenheit, corresponding to the total temperature, which gives the impression that the tests are made with superheated steam actually flowing through the pipe, while as a matter of fact these tests are made with electrically heated pipe. The radiation losses, as well as the temperature of the wall, if superheated steam of the given temperature and superheat were flowing through the pipe, would be considerably less.

Discussion on Accuracy of Boiler Tests

(*Continued from page 430*)

Nevin E. Funk[3] asked whether the author's statements regarding the sampling of steam were a theory or had been subjected to rigorous test. He pointed out that saturated steam was not, as a rule, generated in modern boilers as they are generally equipped with superheaters. He could see no reason for stating the performance of a boiler in B.t.u. per 100 B.t.u. in the coal, as suggested by the author, as it would be the same as stating the efficiency.

Edwards R. Fish,[4] who presented the paper in the absence of the author, said, in closing the discussion, that differences of opinion had been expected, and that the opinions expressed only illustrated the fact that the whole art was more or less uncertain. He spoke of the new boiler test code and its emphasis upon accuracy. The boiler tests shown by the author were of commercial rather than research type and were subject to greater variations than the latter type, but were made by highly trained experts with the best of apparatus and refinements. The author's remarks about sampling steam were based on theory; no attempt had been made to check them.

In a discussion submitted after the meeting R. F. Burke[5] criticized the steam-sampling nozzle recommended by the A.S.M.E. Boiler Test Code and suggested a calorimeter nozzle having three openings, one in the center and one near each side, proportioned so that the velocity of the steam will be the same through the calorimeter nozzle and calorimeter. Mr. Burke spoke of the difficulties of getting accurate coal-consumption figures in short tests. He stated as his belief that the correct way to judge the amount of coal on the grates of an underfeed stoker is by the draft differential, which should be the same at the beginning and end of a test. He called attention to the possibility of error in measuring water unless constant level starting fifteen minutes before the test is maintained throughout the test. He further expressed the opinion that the efficiency of boilers should be determined upon temperature and flue-gas analysis rather than on the amount of coal burned and water evaporated.

The Control of Boiler Operation

Simplified Formulas for Use in Calculating Chimney, Combustion and Absorption Losses —A Proposed Fuel Unit for Bituminous Coal, etc.

By E. A. UEHLING,[1] MILWAUKEE, WIS.

The problem the author sets for himself is to suggest a method that will bring complete and intelligent control of boiler operation, so far as combustion and absorption efficiency are concerned, within the horizon of comprehension and easy execution of the average operating engineer, enabling him to determine heat losses and to separate them into their several components so that he can know just where and to what extent losses occur, and that he may be better able to minimize them by intelligent application of the proper remedy. The author proposes the pound-carbon fuel unit, which he shows to be practically equicalorific, and which in B.t.u. equals 14,450 plus 62,000 times the percentage of available hydrogen.

Formulas are presented for calculating heat losses up the chimney and the combustion and absorption losses are analyzed. The application of the formulas to some scientifically conducted tests is shown.

OUR Government, through its research departments of the Bureau of Mines and the Geologic Survey has made and published thousands of analyses, ultimate as well as proximate, covering all the coals of the United States, Alaska, etc. These analyses are all available and they are both interesting and instructive; but long tables of analyses are of no practical use to the operating engineer. He must have specific information of the ratio of heat input to the heat utilized or the heat wasted, it matters not which, in order to know how efficiently or wastefully his boilers are operating.

The Equicalorific Fuel Unit

The pound of coal as received is and will probably remain the commercial fuel unit, but because of great variation in heating value it is a most unsatisfactory control unit. This has long been recognized by combustion experts, and the pound of combustible has been adopted as the fuel unit for comparing boiler efficiencies. This unit, although it eliminates the variation in heating value due to the ash and moisture in coal, is practically equicalorific only between narrow limits of oxygen.

The heating value of the pound-carbon fuel unit is 14,550 + 62,000H_a B.t.u., where H_a is the available hydrogen per pound of carbon, and for practical control purposes this unit is essentially equicalorific, as is shown in the complete paper.

Methods for Ascertaining Economic Operation

There are two distinct methods for ascertaining the economic operation of a boiler:

- *a* By determining the percentage of the heat in the fuel utilized
- *b* By ascertaining the percentage of heat wasted.

The first is the simpler and therefore most generally practiced way. It answers well as an overall control, but does not raise the endeavor to improve boiler operation beyond the old cut-and-try methods, hence cannot lead to continuous maximum boiler efficiency. The second method, as practiced when attempted at all, is apparently more intricate and difficult than the first, and is but little understood by even the most up-to-date operating engineer. The heat losses are determined by the combustion experts for the purpose of establishing a heat balance, but heat balances mean little or nothing to the average operating engineer, and even when understood and appreciated they are of little or no help to him in controlling boiler operation. The engineer is continually confronted by contradictory advice: On the one hand, he is told that CO_2 is the all-important control factor. Keep CO_2 a maximum and heat losses will be a minimum. Carbon dioxide is the index of efficiency. On the other hand, he is admonished that CO_2 is an unreliable index; high CO_2, because of accompanying CO, is likely to cause greater heat loss than low CO_2. A third person tells him not to bother about CO_2 and CO but to keep air flow and steam flow in unison and maximum efficiency will result. Confronted by such conflicting statements, operating engineers and many power-plant managers become confused rather than enlightened.

Boiler efficiency rests on combustion efficiency and absorption efficiency and these are as distinct one from the other as boiler efficiency is from engine efficiency. The first is a chemical phenomenon which can be adequately diagnosed only by chemical means, and the second a physical phenomenon which must be diagnosed by physical means; without adequate diagnosis the remedy must be guessed at, and if it happens to be guessed correctly it is rarely intelligently and effectively applied. This is a scientific truism which must be borne in mind if we are to attain and maintain maximum economy in the operation of steam boilers. All other methods of control, helpful though they may be, cannot lead to maximum efficiency.

The heat carried to waste up the chimney can be ascertained only by analyzing the gas and measuring its temperature on leaving the boiler. To exercise intelligent control the heat in the gas must be divided into available and unavailable heat. The latter depends on the theoretical maximum percentage of CO_2 obtainable from the fuel used and the temperature of the water in the boiler.

This temperature, below which it is impossible to cool the gas by absorption, depends on the steam pressure which is practically constant for any given boiler, and since the maximum percentage of CO_2 is also constant, it follows that unavailable heat in the gas must be constant. The difference between the total heat and the unavailable heat is the available heat loss. The available heat loss is again composed of two parts, viz., that due to excess air and that caused by excess temperature. This analysis of the heat loss provides the means for intelligent control of boiler operation.

To enable the operating engineer to ascertain and analyze his heat losses he must know the percentage of CO_2, the temperature of the gas as it leaves the boiler and the boiler draft. These three controlling factors must be continuously autographically recorded. The percentage of CO must be kept within tolerable limits, as will be shown further on in the paper.

The temperature of the gas depends on:

- *a* The rate of combustion
- *b* The cleanliness of the heating surface
- *c* The condition of the baffling
- *d* The tightness of the setting.

The boiler draft is affected by all of these conditions and is therefore essential to interpret properly the cause of temperature variation. The product of the square root of the boiler draft and the CO_2 is a reliable index to the rate of combustion when the boiler and setting are in good condition.

Having autographic records of the essential control factors is one thing; to make effective use of the information they contain is quite another. Records of whatever kind are useless unless they are regularly scrutinized and correctly interpreted and compared and the information deduced promptly applied. To apply this information intelligently it must be put into concrete form, i.e., into B.t.u. and percentage of the heat supplied; and here is where the average operating engineer is practically helpless and it is the real cause of the adverse attitude already referred to, his aversion to scientific methods of control. To overcome this attitude heat-loss calculations must not only be brought within the horizon of his ready comprehension, but they must be made so easy that he can make them with the least trouble and expenditure of time.

---

[1] Consulting Engineer. Mem. Am.Soc.M.E.

Abridgment of paper presented at the Spring Meeting, Atlanta, Ga., May 8 to 11, 1922, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. All papers are subject to revision.

The Author's Heat-Loss Formulas

In an appendix to his paper on the Physical and Chemical Control of Boiler Operation,[1] the author deduced a set of formulas for calculating the heat losses up the chimney, which are again presented below in slightly modified form. These formulas attracted no attention at the time nor have they since, at least no comment upon them has come to his notice. The reason for this may have been that they are all based on the pound-carbon fuel unit, the advantages of which were not then apparent.

The formulas are as follows:

$L_d = (0.24 + 58.46/CO_2) \times (T - t)$
= B.t.u. carried to waste by the dry gas . . . [1]

$L_c = 10{,}150\ CO/(CO + CO_2)$
= B.t.u. loss due to CO contained in gas . . . [2]

$L_h = H_t \times [(10{,}642 - 9t) + 4.3(T - 212)]$
= B.t.u. carried to waste by the steam contained in the gas:
H_t = weight of total hydrogen per pound of carbon in the coal, including the moisture . . . [3]

$$A_e = \frac{2100}{(1 + 3H_a) \times CO_2} - \frac{100 + 238H_a}{1 + 3H_a}$$
= per cent excess air . . . [4]

$O_e = 21 - CO_2 \times (1 + 2.38H_a)$
= per cent excess oxygen . . . [5]

$MCO_2 = 21/(1 + 2.38H_a)$
= maximum per cent of CO_2 obtainable from the fuel burned . . . [6]

$A_a = 243.6/CO_2 + 8Ha$
= pounds of air supplied per unit of fuel consumed . . . [7]

$G_w = 1 + 243.6/CO_2$
= pounds of dry gas produced . . . [8]

$A_v = 3192/CO_2$
= cu. ft. of dry gas at 62 deg. fahr. . . . [9]

$S_w = 9H_t$
= pounds of steam in gas . . . [10]

Z = square root of the boiler draft . . . [11]

$Z \times CO_2$ = index of rate of combustion . . . [12]

The Control Factors

To establish a heat balance the B.t.u. supplied by the air must be deducted from the heat in the gas, hence the temperature factor $(T - t)$ must be used in Formulas [1] and [3], but as already stated, heat balances are of no use for direct, prompt, and continuous control. To enable the operating engineer to exercise effective control over combustion and absorption efficiency, he must know not only how much heat is carried to waste by the gases, but how much of this heat is available to the boiler and what part of the available heat loss is chargeable to the process of combustion and how much to absorption; and since all the heat brought in by the air is contained in the unavailable part of the heat in the gas, the temperature of the air may be ignored, thus simplifying the formulas by eliminating a variable term. The calculations for determining the two essential control factors are:

$A = (0.24 + 58.46/CO_2) \times T$ = total B.t.u. in the dry gas, and

$B = (0.24 + 58.46/MCO_2) \times T_w$ = unavailable B.t.u. in the dry gas; then

$A - B$ = the theoretically available heat carried to waste by the dry gas. In Formula [3] the term $H_t(10{,}642 - 9t)$ represents latent heat which is all unavailable, hence if we let

$C = (4.3H_1) \times (T - 212)$ = total sensible heat in H_2O in the gas, and

$D = (4.3H_1) \times (T - T_w)$ = unavailable sensible heat in H_2O in the gas, then

$C - D$ = available heat in H_2O contained in the gas, hence

$(A + C) - (B + D) = E$ = total available heat carried to waste up the chimney.

The heat loss E is partly due to combustion and partly to absorption inefficiency.

Combustion and Absorption Losses

Combustion would be 100 per cent efficient if all the combustible elements in the fuel were completely oxidized in the furnace, using the theoretical weight of air required, and absorption would be 100 per cent efficient if it reduced the temperature of the gas resulting from 100 per cent efficient combustion to the temperature of the water in the boiler. The component parts of combustion losses are:

a The heat loss due to excess air
b The heat value of the unburned combustible in the gas $(CO + C_x + H_y)$, and
c The carbon in the ash.

The component parts of the absorption losses are:

a Heat loss due to dirty heating surface
b Heat loss due to defective baffling, and
c Heat loss due to excessive driving.

All these component parts of the waste of available heat can be determined from the interrelation between the three essential autographic records, for any particular time or any desired period, such as a test, a day or a shift, as follows:

Applying our formula we have:

$a = [(0.24 + 58.46/CO_2) - (0.24 + 58.46/MCO_2)]T$
= B.t.u. loss due to excess air.

The combustible constituents in the gas are CO and an undetermined weight of $(C_x + H_y)$. The heat value of the latter probably never exceeds 0.2 of the former in boiler flue gas, and is negligible when CO is kept within proper limits.

$b = 10{,}150\ CO/(CO + CO_2)$ = B.t.u. loss from CO in the gas.

c The B.t.u. loss due to unburned carbon must be determined by analyzing the ash. We have then

$C_{ef} = 100 - (a + b + c)/179$ = combustion efficiency.

The component parts of heat lost to absorption can be located on the autographic charts, but can be quantitatively determined by our formula only in total; thus:

$$A_{ef} = 100 - \frac{(0.24 + 58.46/MCO_2) \times (T - T_w)}{179}$$
= absorption efficiency.

The component parts of absorption loss may, however, be approximately determined, as will be shown by example further on.

Simplification of Formulas

All this may look like a rather formidable array of equations to place before the average operating engineer, with the expectation that he apply them successfully. Such expectation would be futile. The author, however, is not now confronting average operating engineers; he imagines he is addressing scientific as well as practical fuel conservationists and combustion experts, who will understand that the foregoing formulas are applicable to all commercial fuels from coke to natural gas, whereas operating engineers rarely have to deal with more than one kind of fuel at a time. Limiting ourselves for the present to bituminous coal, these formulas, being based on the equicalorific fuel unit, can be greatly simplified and those essential for control reduced to few in number.

In Formula [1] the factor $(0.24 + 58.46/CO_2)$ is equal to the B.t.u. per degree of temperature contained in the weight of dry gas produced in burning one unit of fuel. Letting X equal this value, then XT = total B.t.u. in dry gas per unit of fuel. Substituting the average value of H_a (= 0.051) in Formula [6], we have $MCO_2 = 21/1.128 = 18.6$ per cent = the theoretical maximum percentage of CO_2 obtainable from bituminous coal. Using this value of CO_2 in Formula [1] we have $(0.24 + 58.46/18.6) \times T_w = 3.38T_w$ = B.t.u. of unavailable heat in dry gas. T_w varies with steam pressure, but since this is practically constant for any given boiler plant, $3.88T_w$ is also constant. $XT - 3.38T_w$ = B.t.u. of available heat. Now since X represents the total B.t.u. per degree of temperature in the weight of dry gas resulting from the combustion of one unit of fuel burned with an excess of air, and 3.38 = B.t.u. of heat per degree of temperature in the weight of gas that results when a unit of fuel is burned with the theoretical weight of air required for complete combustion, we have $(X - 3.38)T$ = B.t.u. of available heat wasted because of excess air and $3.38\ (T - T_w)$ = B.t.u. of available heat wasted due to excess temperature.

---

[1] Trans. Am.Soc.M.E., vol. 40, p. 714.

In Formula [2], 10,150 CO ($CO + CO_2$), the factor CO ($CO + CO_2$) represents the weight of carbon burned to CO. This formula can be somewhat simplified by letting $10{,}150 \times CO = Y$ so that Y ($CO + CO_2$) = B.t.u. wasted due to CO.

Our essential control formulas are then:

XT = total B.t.u. contained in dry gas................[A]
$3.38\ T_w$ = B.t.u. unavailable in dry gas..............[B]
$XT - 3.38T_w$ = B.t.u. available in dry gas..........[C]
$(X - 3.38)\ T$ = B.t.u. loss due to excess air..........[D]
$3.38\ (T - T_w)$ = B.t.u. loss due to excess temperature..[E]
$Y\ (CO + CO_2)$ = B.t.u. loss due to CO in gas........[F]
$Z \times CO_2$ = index to rate of combustion..............[G]

The value of $3.38T_w$ is practically constant for any given power plant. The values of X, Y and Z may be read off directly from tables prepared for the purpose or they may be found from curves as shown in Fig. 1. Only a fraction of the B.t.u. in the steam contained in the gas is sensible heat and the greater part of this is unavailable to the boiler. The heat loss represented by Formula [3] therefore has no control value and may be ignored. By substituting the value of $H_a = 0.054$ in Formulas [4], [5] and [6], they reduce respectively to—

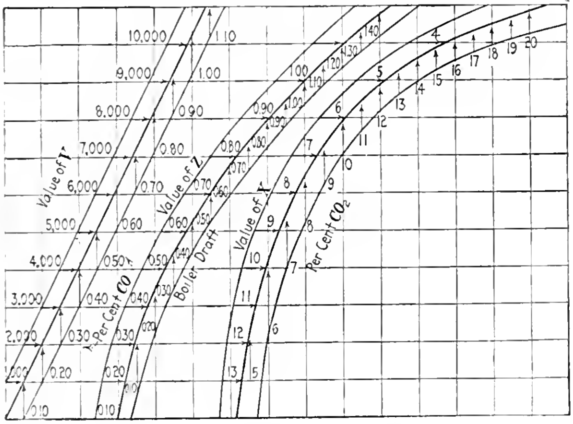

Fig. 1 Values of X, Y and Z

A_e = $1810.35/CO_2 - 97$ = per cent excess air.......[4a]
O_e = $21 - 1.13CO_2$ = per cent excess oxygen........[5a]
MCO_2 = 18.6 = maximum per cent CO_2.............[6a]

The information derived from [4a] and [5a], though not essential for control purposes, may be desirable to have.

Combustion and absorption efficiency are the two factors on which economical boiler operation depends. Maximum absorption efficiency in any given boiler is maintained by keeping the boilers clean inside and out, and maintaining the baffling and setting in perfect condition. The former is a matter of routine conscientiously performed and the latter can be secured by proper and frequent inspection. If the proper tools are supplied, maintaining absorption efficiency is a simple matter. Combustion efficiency, on the other hand, is an entirely different proposition and cannot be maintained by any definite predetermined routine of operation. It depends on numerous and frequent adjustments: The rate of combustion must be adjusted to the steam demand. The draft must be adjusted to maintain the rate of combustion, the coal supply must be kept in harmony with the draft, and the firebed must be kept in condition to make the draft economically effective. The air supply must be adjusted so that the proper proportions enter, respectively, below and above the firebed. None of these adjustments can remain fixed but must be frequently changed as a whole and in relation to one another if maximum combustion efficiency is to be achieved.

It is not possible to maintain maximum combustion efficiency by inspection. Without the aid of the proper and necessary means for getting the essential data, boiler operation is necessarily a more or less haphazard performance, depending on intuition and guessing. To achieve the best results in any undertaking proper instruments must be provided. This is as true of operating boilers as it is of navigating a ship or conducting a scientific research. Suppose that in addition to the steam gage and water glass, which are always supplied (because required by law), the necessary instruments, viz., an Orsat, a continuous recording CO_2 meter and indicator, a recording pyrometer and a boiler draft gage have been properly installed. The first and most important step necessary to insure success is to put some one in charge and hold him strictly responsible for the continuous and correct functioning of the instruments. The principal cause for failure of such instruments is due to overlooking or neglecting this necessity. A further reason why so many installations of these instruments have not led to the results predicted or anticipated is that the operating engineer has had no simple means for getting the information autographically recorded into the form necessary for direct and intelligent application.

The object of the simplified control formulas is to bring the mathematics necessary to determine and locate the losses within easy reach of the average operating engineer, and especially to enable him to make the necessary calculations with the least expenditure of time and trouble. The fact that these formulas are based on the equicalorific fuel unit gives them a much greater practical value than their simplicity would indicate. It makes effective control of boiler operation quite independent of the analysis and heating value of the coal as fired. If the necessary equipment is provided, any up-to-date operating engineer should by the aid of such equipment and the simplified formulas be able to maintain the highest combustion and absorption efficiency that the structural and operating conditions of his plant (including the quality of the fuel used) will permit, and if maximum combustion and absorption efficiencies are maintained, minimum waste of fuel will necessarily result.

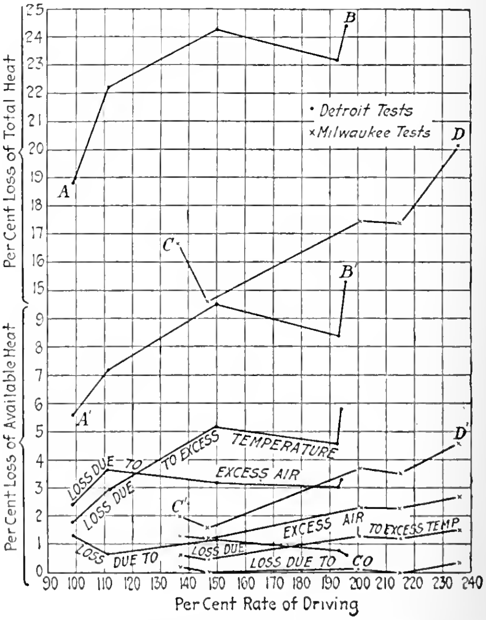

Fig. 2 Graphical Representation of Application of Heat-Loss Control Formulas

Application of Formulas

Tables 1 and 2 show the application of the heat-loss control formulas to ten scientifically conducted tests. These tables are self-explanatory. The tests treated in Table 2 were taken from the series of tests made of the large boilers of the Delray Plant of the Detroit Edison Company by Dr. Jacobus[1] as reported to

---

[1] Trans. Am.Soc.M.E., vol. 33, p. 565.

this Society in the paper which he presented at the Annual Meeting in December, 1911. Table 1 treats of the pulverized-coal tests made by Henry Kreisinger of the boilers of the Lakeside Power Plant of the Milwaukee Electric Railway and Light Co. as reported at the Spring Meeting, 1921. All the five tests reported are represented.

TABLE 1 UEHLING HEAT-LOSS CONTROL FORMULAS APPLIED TO THE PULVERIZED-COAL BOILER TESTS OF THE LAKESIDE POWER PLANT, MILWAUKEE

	Data Essential for Control				
Number of test	1	4	3	2	5
CO_2 = Per cent carbon dioxide in gas	15.8	16.0	11.7	14.6	14.1
CO = Per cent carbon monoxide in gas	0.05	0.00	0.03	0.00	0.09
T = Temperature of gas on leaving boiler, deg. fahr.	434	430	482	475	490
T_w = Temperature of water in boiler, deg. fahr	409	409	411	411	411
B_d = Boiler draft, i.e., resistance to gas through boiler, in water	0.30	0.355	1.03	0.92	1.2
RESULTS OF TESTS					
Pounds of coal consumed per hour	5980	6650	9560	9740	11350
Units of fuel consumed per hour	4111	4319	6331	6545	7424
Per cent rate of driving	137	147	209	215	236
Per cent boiler efficiency	83.3	85.4	82.5	82.6	79.8
CONTROL FACTORS OBTAINED FROM FIG. 5					
X = B.t.u. in dry gas per unit of fuel and degree of temperature	3.94	3.9	4.17	4.24	4.38

$100 - (a + b + c)\%$ = Combined combustion and absorption efficiency, per cent	94.4	92.8	90.5	91.6	89.7
ZCO_2 = Index of the rate of combustion	3.74	5.67	8.14	11.46	12.46

The results of applying the heat-loss control factors are graphically shown in Fig. 2. The graph *AB* represents the percentage of total heat wasted, i.e., 100 minus the per cent efficiency as found by tests of the Detroit Edison Company's boilers; and *CD* represents the total heat wasted as found by test of the Milwaukee Electric Railway and Light Co.'s boilers. *A'B'* and *C'D'* show the respective losses of available heat of these two sets of tests as determined by the control formulas. The other graphs show where and to what extent the loss of available heat took place. Comparing graphs *AB* and *CD*, respectively, with *A'B'* and *C'D'*, it will be seen that they are quite similar in contour, and this close similarity demonstrates the reliability of the loss of available heat as an index of boiler efficiency. The reliability of this index can be disturbed only by excessive moisture in the coal or excessive loss of carbon through the grate. The former adds to the unavailable heat and hence cannot be controlled by the operating engineer, and much less by the fireman; the latter can be detected and roughly estimated by observation

and promptly remedied. Fig. 3 shows the rate of combustion in its relation to the combustion index ZCO_2. As the graph shows, this necessarily varies with the type and size of boiler, the arrangement of baffling, etc. The characteristic of the graph must be determined for each type and construction of boiler. This done, it becomes a practically reliable check on the effort of the fireman to burn his proper share of coal in keeping up the steam pressure. Since the percentage of CO_2 is the principal factor in determining combustion efficiency as well as this index, the inefficient fireman is compelled to work harder to make his proper share of the steam.

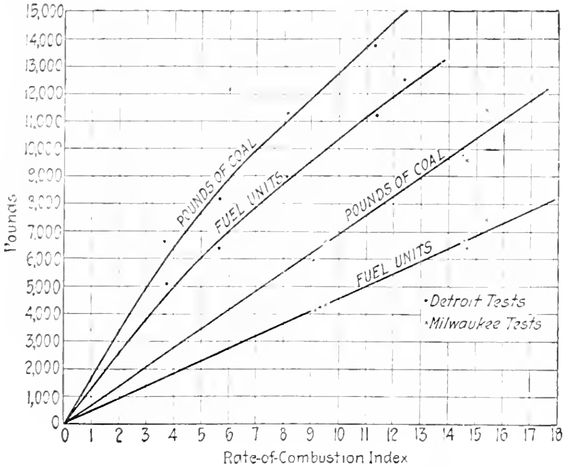

Fig. 3 Relation of Rate of Combustion to Combustion Index, ZCO_2

The loss of available heat up the chimney, as is shown by the tables and graphs, is due to three causes: excess air, excess temperature and CO. The components of this heat loss are shown by the tables and in Fig. 2. These losses can be quantitatively illustrated as shown in Fig. 4. The rectangle *ABCD* represents the total heat carried to waste by the dry gas, and *AGFE* the heat unavailable to the boiler. *EHJD* represents the loss of theoretically available heat due to excess air, *GIHF* that due to excess temperature and *IBCJ* to CO. Now supposing that the excess air had been increased so as to reduce the CO_2 to 10 per cent, the loss of available heat would have been increased by *DCLK*; assuming the temperature to remain the same and the percentage of CO also unchanged the loss due to the latter would be increased as shown by *CJML*. But supposing that the CO had been eliminated by this reduction in CO_2, the gain would have been 1.3 per cent and the loss 4.8 per cent, resulting in a net loss of 3.5 per cent. This is not the place to discuss this phase of the problem, except to call attention to the fact that care must be exercised in eliminating CO at the expense of CO_2, since the loss is liable by far to exceed the gain. Complete combustion is by no means synonymous with most efficient combustion. The greatest practical value of this method of control consists in its simplicity as well as its adequacy. Three autographic records preferably on the same chart are all that is required to furnish the necessary data. The calculations are of the simplest nature and the method is quite independent of the analysis of the coal and its variable heat value as long as it is true bituminous coal, i.e., with oxygen within the limits of 3 to 12 per cent. The heat brought in by the air is contained in the unavailable heat, hence does not affect the reliability of the control. The loss of available heat is the only loss that need be considered because it is the only loss that is controllable. This method of control fixes the responsibility, inasmuch as it separates the heat loss into two parts, namely, combustion loss controllable by the fireman, and absorption loss controllable by the boiler cleaners.

This may be a bold statement considering the present general state of the art and science of boiler operation, but the author hopes and believes that this method of control is a step in the right direction. If it is not, he wants to be set straight; if the method is fallacious, this is the time and place to disprove the claim he makes for it. So far as the equicalorific fuel unit is concerned the author has no fear that it will be upset. There may be exceptional coals within the prescribed oxygen limits that will not come within the practically allowable limits of the equicalorific heating value, but there will be few if any. The average analysis of the coal used in the five Detroit tests varied 4.75 per cent in ash, 2 per cent in oxygen and 804 B.t.u. in heating value, while the separate analyses of the same coal varied as much as 1000 B.t.u.; whereas the variation in the heating value of the pound-carbon fuel unit as determined from the average analysis of the coal used in these tests differs from the equicalorific heating value by only 372 B.t.u. The heating value of the coal used in the five Milwaukee tests varied 834 B.t.u.; the oxygen not being given in the analysis, the variation in the pound-carbon fuel unit could not be determined, but as found from the analyses of representative samples of Illinois coal, the pound-carbon fuel unit is practically equicalorific. The highest heating value of the coal used in the Detroit tests was 14,493 B.t.u. and the lowest of that used in the Milwaukee tests was 11,483 B.t.u., a difference of over 3000 B.t.u., but, as we have seen, this difference in heating value per pound of coal does not affect the constancy of the equicalorific fuel unit nor the practicability of the heat-loss control formulas based thereon.

The author has placed emphasis on the necessity of getting the attitude of mind of the operating engineer in line with the endeavor of the Fuels Division to reduce the consumption of fuel in the production of steam to a minimum. To make worthwhile progress there must be coöperation from the fireman up to the owner or managing director of the steam-power-producing and coal-consuming plants. The urge for the necessary equipment should come from below and be granted from above. To this end education is necessary at the top and at the bottom as well as in between.

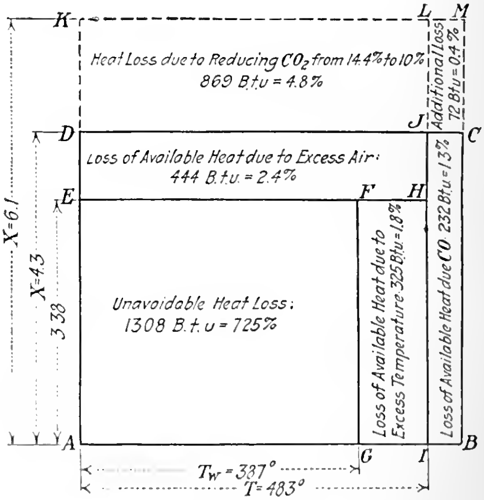

Fig. 4 Heat-Loss Diagram

The ten boiler tests illustrating the application of the author's control formulas show what can be accomplished in the way of economic boiler operation. The average efficiency of boilers in plants the country over is from 15 to 20 per cent below these high standards. The reasons for the slow progress, in the author's judgment, have been: (1) Lack of fundamental control principles which can be readily understood and easily applied by the operating engineer; (2) lack of knowledge and appreciation, by the owners and managers, of the preventable waste of fuel in their plants; (3) lack of coöperation between instrument maker and the purchaser of such instruments; (4) lack of equipment of the necessary instruments; and (5) last but not least, lack of proper instruction to enable the operating engineer to coördinate and interpret the information autographically recorded when such instruments are supplied.

Discussion

Nevin E. Funk[1] opened the discussion of Mr. Uehling's paper as follows: "In Par. 26 the author says: 'If the necessary equipment is provided, any up-to-date operating engineer should by the aid of such equipment and the simplified formulas be able to maintain the highest combustion and absorption efficiency that the structural and operating conditions of his plant (including the quality of the fuel used) will permit, and if maximum combustion and absorption efficiencies are maintained, minimum waste of fuel will necessarily result.'

"That can be done hour by hour or minute by minute by the use of the scheme he has outlined. Of course, it is of some value to know the next day what you have done, but it is far better to arrange the control equipment so that it is possible to know that the coal is burned efficiently at the moment of its burning, but the writer does not believe this scheme has done that.

"The author says: 'If the proper tools are supplied, maintaining absorption efficiency is a simple matter.' That is a very good statement. The writer cannot see, however, that Mr. Uehling has stated the proper tools in this paper. There is an attempt at a statement in another paragraph where the author says: 'in addition to the steam gage and water glass, which are always supplied (because required by law), the necessary instruments, viz., an Orsat, a continuous recording CO_2 meter and indicator, a recording pyrometer and a boiler draft gage have been properly installed.' These are the instruments he needs to check this boiler efficiency scheme. It will be noticed there is no output measurement on the boiler. If the operator does not know the output of the boiler, how does he know the correct draft? The results will be hit or miss. He guesses it by looking at the fire, and if there is more than one boiler, or if there are several men running a bank of boilers, there is a probability that one man may keep a splendid fire above and make the other fellow take the ragged ends, and so it seems that a very important instrument has been left out of Mr. Uehling's statement, that is, a steam-flow meter or a water-flow meter, either one, which shows at what output the boiler is delivering every instant.

"Then, to match up the readings of some of these meters, such as a draft gage, there must be a table on the boiler telling what the draft should be for each output, or some scheme should be used to give a man an indication of his performance during the period of the steam flow.

"These comments have been in a way destructive, but the writer does not want to leave the impression that he feels that this paper is not important, because he thinks it is. He does not believe that the method has given the means of putting in the operator's hands accurate control of good combustion."

A. T. Hutchins[1] presented a written discussion and a curve in which he had plotted gas analyses from the Detroit Edison Co.'s tests, the New York Edison Co.'s tests, and the formula proposed by Mr. Uehling.

F. G. Cutler[2] said that the author had overlooked one phase of the subject, that applied to steel-plant operation, particularly with blast-furnace or by-product gases. With by-product gas the best CO_2 content is around 7 per cent, he said, and with blast-furnace gas it is from 22 to 25 per cent.

Steel for Forge Welding

By FRANK N. SPELLER,[1] PITTSBURGH, PA.

In this paper the principal factors—method of manufacture, chemical composition, fluxing quality, susceptibility to heat and welding temperature—affecting the welding quality of steel are discussed and the average results of 80 tests made on forge welds of hammer-welded pipe are compared with the original material. In addition it is stated that tests have demonstrated that both steel not over 0.15 per cent carbon and minimum tensile strength of 47,000 lb. per sq. in. and that not over 0.20 per cent carbon and minimum tensile strength of 52,000 lb. per sq. in., are satisfactory for forge welding of pipe lines, penstocks, tank-car work and similar construction. In conclusion the writer states that the most important considerations to produce uniformly good results in the forge welding of steel, are suitable material, well-trained operators and adequate facilities for the control of operations.

THE welding quality of steel and the strength and reliability of such welds depend on a number of factors, which include principally method of manufacture, composition, susceptibility to heat, fluxing quality, the mechanical appliances for handling and controlling the work, and the skill of the operator. There are so many factors present affecting the results that it is often difficult to determine which of these predominates in any particular case. This paper discusses particularly the characteristics of steel for forge welding, with brief reference to other factors which enter the problem.

MATERIAL AND WORKMANSHIP

Method of Manufacture. Wrought iron is most easily welded, probably on account of the presence of about one and one-half per cent of easily fusible cinder, which enables the metal to be welded at a comparatively low temperature and protects it from injurious oxidation at high temperature. For this reason wrought iron can usually be welded without much difficulty, but on account of the presence of this cinder internal defects such as laminations and blisters are more likely to occur after the metal has been brought up to the welding heat. What we term "soft welding steel" may be made by the bessemer or open-hearth process and should be made especially for this purpose, i.e., it should have, as far as possible, sufficient of the characteristics of wrought iron to readily form a "welding scale" at the lowest possible temperature. Very highly refined open-hearth steels, "ingot iron" or electric steel, are, as a rule, lacking in this respect and so far have not shown as good welding quality as soft welding steel or wrought iron.

Composition. It is well known that comparatively small quantities of nickel, chromium and silicon interfere seriously with welding. Each of these should be under 0.05 per cent. Carbon has a lesser effect and should preferably be low, certainly under 0.30 per cent for any kind of forge welding. The higher the carbon, the lower the melting and burning points of the steel. By the burning point we mean the temperature at which the grain growth has increased to such a degree as to cause actual disintegration and intergranular oxidation of the metal. Sulphur under 0.05 per cent is not harmful and under certain conditions more may be present without injurious results. Phosphorus up to bessemer limits is beneficial to welding.

Self-Fluxing Quality. On heating iron or steel above 1500 deg. fahr. an oxide scale is formed. The relation between the fusibility of the oxide scale to the temperature at which the metal "burns" is one of the most important factors determining suitability of the metal for welding. This scale consists usually of the magnetic oxide of iron (Fe_3O_4) with a certain percentage of "sonims"[1] from the iron (MnO, P_2O_5, SiO_2, etc.) which tend to make the scale more fusible. The method of manufacture and composition of the steel have much to do with the formation of a suitable welding scale.

[1] Metallurgical Engineer, National Tube Co. Mem. Am.Soc.M.E.

Abridgment of a paper presented at the Spring Meeting, Atlanta, Ga. May 8 to 11, 1922, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. All papers are subject to revision.

[1] Solid non-metallic impurities in steel, H. D. Hibbard, Trans. A.I.M.E., vol. xli, p. 803 (1910).

The range of temperature between the melting point of the scale and the burning point of the metal is about 100 deg. fahr. in good welding steel and distinguishes this class of steel probably more than any other property. In fact, it is this self-fluxing quality which makes possible the commercial welding of iron and steel. Artificial fluxes, such as borax, may be used to lower the melting point of the scale in welding small parts of high-carbon steel, but at present this is not practicable to apply satisfactorily when working on a large scale. The fusion of the scale also affords the operator a definite indication of the welding point, giving him close control over the operation.

Susceptibility of Metal to Heat. When normal wrought iron or steel is heated above the upper critical point (about 1750 deg. fahr. for soft steel) the grain grows at a rate depending on the temperature and time of heating. When a certain grain size is reached, a disintegration of the metal occurs with intergranular oxidation and the metal becomes "burnt." When this occurs, the metal is red-short and cold-short and useless for most purposes. The actual temperature at which iron or steel is burned depends as much on the protective character and fusibility of the welding scale as anything else. High-carbon steels are more susceptible to damage of this kind in welding than the same class of steel of lower carbon, but the carbon is not the only factor, otherwise we might expect highly refined open-hearth steel or "ingot iron" to weld as easily as charcoal iron.

The large granular structure caused by exposure of the metal to welding temperature may be reduced to a fine structure (unless the metal has been excessively overheated) by a certain amount of mechanical forging applied while the metal is cooling or by reheating the metal to about 30 deg. fahr. above the upper critical point, followed by cooling in the air, which with soft steel may be comparatively rapid.

Welding Temperature. To produce intercrystalline union of two pieces of iron it is necessary that the clean surfaces be brought into close contact with a certain pressure. This is possible even at normal temperature with application of sufficient pressure in the case of soft steel, or may easily be done at a temperature slightly above the fusing point of the scale with comparatively little pressure, or at a lower temperature if the fusion point of the scale is lowered by the use of artificial fluxes, such as borax. So that the most favorable temperature for welding depends on the material and mechanical facilities. The usual temperature at which soft steel is found to weld satisfactorily ranges from 2500 to 2600 deg. fahr.

RESULTS OF TESTS

A number of tests of forge welds (80 in all) made on two rings cut from the ends of hammer-welded pipe, compared with the original material taken from the same pipe, about 1/2 in. thick 90 deg. from the weld, gave results which are summarized as follows:

Material Away from Weld—Average transverse tensile test:

Elastic limit, lb. per sq. in.	32150
Ultimate strength, lb. per sq. in.	52790
Elongation in 8 in., per cent	29.7
Reduction, per cent	58.6

Efficiency of Weld—Test pieces machined to uniform thickness:

Average of all tests (80 tests), per cent	92.7
Average at extreme end (40 tests), per cent	90.3
Average 2 in. or more away from end (40 tests), per cent	95.0
Minimum at extreme end, per cent	69.0
Minimum 2 in. or more away from end, per cent	82.3

The above steel before welding ranged in tensile strength from about 47,000 to 62,000 lb. per sq. in.—most of it being under 57,000 lb. and under 0.16 per cent carbon.

SPECIFICATIONS

This brings us to the question of specifications for steel best suited for forge welding. While skillful operators can undoubtedly make a good job of most steels when the carbon does not exceed that of flange quality, it seems desirable, everything considered, to limit the carbon to about 0.15 per cent for important parts where life and valuable property are at stake and a high efficiency of strength of weld is desired.

The present A.S.T.M. specification (A78–21–T) for forge-welding steel (given in an appendix to the complete paper) calls for steel of not over 0.18 per cent carbon having a minimum tensile strength of 50,000 lb. per sq. in. A.S.T.M. Sub-Committee II of Committee A-1 now has under consideration substituting for this two grades of steel having the following chemical and physical properties:

CHEMICAL COMPOSITION	GRADE A	GRADE B
Carbon, per cent[1]	not over 0.15	not over 0.20
Manganese, per cent	0.35 to 0.60	0.35 to 0.60
Phosphorus, per cent	0.04	0.04
Sulphur, per cent	0.05	0.05
PHYSICAL TESTS		
Tensile strength, lb. per sq. in.	not under 47,000	not under 52,000
Yield point, lb. per sq. in.	not under 25,000	0.5 tensile strength
Elongation in 8 in., per cent	not under 26	not under 24

[1] For plates over 3/4 in. thick, 0.02 additional carbon is permissible.

Steel of both grades has been forge-welded and used in large quantities with an assumed weld efficiency of 90 per cent. The tests we have made indicate that this figure is warranted for pipe lines, penstocks, tank-car work and similar construction. A somewhat lower efficiency or higher factor of safety should, of course, be used for boilers and Class A unfired pressure vessels.

BOILER-CODE REQUIREMENTS

With respect to steel for forge welding, Part I, Section I, Par. 186 of the A.S.M.E. Boiler Code requires that:

> The ultimate strength of a joint which has been properly welded by the forging process shall be taken as 28,500 lb. per sq. in., with steel plates having a range in tensile strength of 47,000 to 55,000 lb. per sq. in. Autogenous welding may be used in boilers in cases where the strain is carried by other construction which conforms to the requirements of the Code and where the safety of the structure is not dependent upon the strength of the weld.

Section III, Par. L-29 reads:

> The ultimate strength of a joint which has been properly welded by the forging process shall be taken as 28,500 lb. per sq. in., with steel plates having a range in tensile strength of 45,000 to 55,000 lb. per sq. in. Autogenous welding may be used in boilers in cases where the strain is carried by other construction which conforms to the requirements of the Code and where the safety of the structure is not dependent upon the strength of the weld.

The proposed section on unfired pressure vessels with reference to forge weldings, Pars. 5 and 8, reads:

> The ultimate strength of a joint which has been properly welded by the forge process shall be taken as 65 per cent of the tensile strength of the plate.

This weld efficiency seems rather low for Class A vessels and we believe that it should be still higher for Class B vessels.

In Pars. 2 and 3 of Sections I and III, firebox and flange steel are specified *for all parts* of the boiler. There seems to be a conflict in these specifications between the requirements for steel which may be forge-welded, although apparently the intention is to use a steel of lower carbon for this purpose. This would seem to be in line with the best experience, but inasmuch as flange steel has apparently been successfully used for some time in forge-welded boiler construction where part of the stress is carried by riveted straps, there would seem to be no reason for not continuing this practice when the weld is so reinforced.

FINISHING

After the weld is made, internal strains remain in the metal which should be released by annealing. This may be done by heating the piece uniformly to a red heat (about 1500 deg. fahr.) and allowing to cool in the air. Any objectionable amount of distortion which has occurred in the welding operation should be removed, preferably while the piece is at an annealing heat; otherwise it should be reformed and then annealed. Some operators prefer one form of scarfing, others none at all. Some use roller welding machines, but the majority use power hammers.[1] Good welding has been done with coke fire, producer gas, natural gas and water gas, the last being best adapted for forge welding on a large scale.

To produce uniformly a high weld efficiency the most important considerations are suitable material, well-trained operators, and adequate facilities for control of the work.

[1] Details of mechanical appliances for hammer welding in modern American plants will be found in articles by E. F. Thum in *Chemical & Metallurgical Engineering*, September 21, 1921, October 19, 1921, and November 16, 1921.

The Evaporation of a Liquid into a Gas

By W. K. Lewis,[1] Cambridge, Mass.

The author investigates the mechanism of the evaporation of a liquid into a gas as applied to such processes as are found in gas scrubbers, humidifiers, dehumidifiers, water coolers, air driers, etc. He establishes a formula for calculating the humidity of air from wet- and dry-bulb thermometer readings, and shows that the coefficient of heat transfer divided by the coefficient of diffusion equals the humid heat of the gas.

A LARGE amount of work has been done on the evaporation of water into air at temperatures below the boiling point. The dynamic equilibrium corresponding to the evaporation of water into air counterbalanced by the flow of heat from the air into the water is the basis of wet-bulb thermometry, the most useful method of determining the humidity of air.[2] In 1886 Desmond Fitzgerald[3] pointed out that the rate of evaporation of water into air is a function of the difference in partial pressure between the moisture in equilibrium with the evaporating water and the actual moisture content of the air in contact with it. It is true that Fitzgerald did not assume the rate of evaporation linearly proportional to this difference, but added a small correction term proportional to the square of the difference. Barrows and Babb[4] made a large number of determinations of evaporation from the surface of Maine lakes, and while their experimental determinations were subject to a large percentage variation, none the less their results substantiate this proportionality. More recently Willis H. Carrier[5] has shown that the rate of water evaporation is, within experimental error, proportional to partial-pressure difference. The following is an analysis of the mechanism of such evaporation.

Preliminary Assumptions

For purposes of formula derivation assume a long tunnel through which unsaturated air is flowing at constant mass velocity. The walls of this tunnel are non-conductors of heat. Along the bottom of the tunnel is placed a mat or wick permanently wet with water supplied from below as evaporation takes place above. The water is furnished to this wick at every point at a temperature exactly equal to that of the water on the upper surface of the wick at that point. There is no motion of the liquid water parallel to the axis of the tunnel. The mass velocity of the air over the water is constant and sufficiently low so that heat generated by friction may be neglected.

The unsaturated air entering this tunnel will become humidified in passing through it owing to the evaporation of water. In consequence, the temperature of the air will fall, and if the tunnel be sufficiently long, the water and air will ultimately come to equilibrium.

Notation

In the formula to be derived, the following notation is used:

A = Area of liquid in contact with gas

H = Absolute humidity of gas, or parts by weight of vapor per part by weight of vapor free gas

h = Surface coefficient of conductivity of heat between gas and liquid, or B.t.u. per unit time per unit surface area per unit temperature difference

k' = Coefficient of diffusion, or parts by weight of vapor diffused per unit time per unit area per unit absolute humidity difference

k = Coefficient of diffusion, or parts by weight of vapor diffused per unit time per unit area per unit vapor pressure difference

p = Partial pressure of vapor

P = Total pressure of vapor and vapor-free gas (i.e., barometer)

θ = Time

t = Temperature

r = Latent heat of vaporization

s = Humid heat, or number of heat units necessary to change the temperature of unit weight of vapor-free gas, *plus the vapor it contains*, one degree

W = Weight of liquid evaporated.

Interaction of Water with Air

Now consider for the moment the conditions at any given point along the length of this tunnel. At this point the temperature, absolute humidity, and pressure of water vapor in the air will be represented by t, H and p. Since the apparatus is continuous in its operation these conditions will remain unchanged at this particular point, but will vary from point to point along the tunnel. The corresponding quantities representing the condition of the liquid water in contact with the air at this particular point are t_w, H_w and p_w.

The mechanism of interaction of the water with the air is as follows: There exists over the water what is equivalent to a stationary film of air, which insulates the water from the main body of the air. Through this air film heat is diffusing from the air into the water and through the same film there is diffusing, in the opposite direction, the water vapor formed by evaporation on the surface of the liquid. This evaporation cools the surface of water, and, since it is available from no other source, heat must be supplied solely by diffusion from the air. The heat of vaporization must therefore be quantitatively compensated by the heat flow through the surface film, and the rate of evaporation is limited by the rate of diffusion of vapor through the same film.

From the foregoing one can immediately write the following equations:

$$-\frac{dW}{A d\theta} = k'(p_w - p) \quad \ldots\ldots\ldots\ldots\ldots\ldots [1]$$

$$\frac{dQ}{A d\theta} = h(t - t_w) \quad \ldots\ldots\ldots\ldots\ldots\ldots [2]$$

$$dQ = -r_w dW \quad \ldots\ldots\ldots\ldots\ldots\ldots [3]$$

Whence

$$p_w - p = \frac{h}{k' r_w}(t - t_w) \quad \ldots\ldots\ldots\ldots\ldots\ldots [4]$$

This last equation is the one normally used for calculating the humidity of air from wet- and dry-bulb thermometer readings. In it, variation in r_w is neglected and the term $h/k'r_w$ is assumed constant. For p in millimeters of mercury and t in deg. cent., it equals 0.5. The equation implicitly assumes that the cooling of the air is differential, i.e., so small in the neighborhood of the point in question that the actual changes in temperature and humidity of the air, t and p (or H), are negligible.

Since

$$p = P\frac{\frac{H}{18}}{\frac{H}{18} + \frac{1}{29}} \quad \ldots\ldots\ldots\ldots\ldots\ldots [5]$$

$$t - t_w = \frac{k' r_w}{h} P\left(\frac{\frac{H_w}{18}}{\frac{H_w}{18} + \frac{1}{29}} - \frac{\frac{H}{18}}{\frac{H}{18} + \frac{1}{29}}\right) \quad \ldots\ldots\ldots\ldots\ldots\ldots [6]$$

Where H is small, as is usually the case below 150 deg. fahr., $\frac{H_w}{18}$

---

[5] Am. Soc. Refrigerating Engineers' Journal, May, 1916, vol. 2, no. 6, p. 23.

Paper presented at the Spring Meeting, Atlanta, Ga., May 8 to 11, 1922, of The American Society of Mechanical Engineers. Slightly abridged. All papers are subject to revision.

and $\frac{H}{18}$ are negligible compared with $\frac{1}{29}$, and one may write, as a close approximation,

$$t - t_w = \frac{kr_w}{h}(H_w - H) \quad \text{[7]}$$

where

$$k = 29k' \frac{P}{18}$$

It is obvious that h and k depend on the thickness of the air film and are therefore functions of the velocity of the air. It is, however, equally obvious that if air velocity be increased sufficiently to double the one, the other will double also. The ratio of h/k therefore remains constant, independent of velocity. This explains why the reading of a wet-bulb thermometer is uninfluenced by the velocity of air passing it, provided the velocity is sufficient so that any heat lost by radiation is negligible in comparison with that picked up by conduction.

The Relation $h/k = s$

Now consider the change in humidity and temperature of the air as it moves along the tunnel. Starting at the same point previously considered, the air will drop in temperature by an amount dt and increase in humidity by an amount dH. The heat given up by cooling must correspond to the heat of vaporization of the water picked up, i.e.,

$$-s\,dt = r_w\,dH \quad \text{[8]}$$

whence, assuming constancy of s and r_w,

$$H = -\frac{s}{r_w}t + \text{const.} \quad \text{[9]}$$

Assuming the tunnel indefinitely long, the air will ultimately become saturated at some temperature t_e, and humidity H_e. Since these conditions represent equilibrium between the air and the water, evaporation will cease, and t_e and H_e are therefore the constant, fixed end-points of the process. Inserting these limits,

$$H_e - H = \frac{s}{r_w}(t - t_e).$$

We have now derived two formulas connecting H and t, both applying to this same process of evaporation, i.e.,

$$H_e - H = \frac{s}{r_w}(t - t_e)$$

and

$$H_w - H = \frac{h}{kr_w}(t - t_w)$$

These two expressions must therefore be identical. By the method of undetermined coefficients this can be true only provided the corresponding coefficients are equal, i.e.,

$$\frac{s}{r_w} = \frac{h}{kr_w}, \text{ or } s = \frac{h}{k}$$

and $t_w = t_e$, a constant; and $H_w = H_e$, also constant.

So far the discussion has been limited to water and air. Obviously, however, the same relationships must apply to any liquid and any gas with which its vapor is mixed.

The first of these equations, $h/k = s$, states that the coefficient of heat transfer divided by the coefficient of vapor diffusion through the gas film is constant, and equal to the humid heat of the gas. By means of Formula [1] the ratio h/k can be calculated from the observed wet- and dry-bulb temperatures for any vapor-gas mixture of a known gas humidity. The experimental determinations of wet-bulb temperatures for water-air, water-carbon dioxide, toluol-air and chlorbenzol-air, and calculations for h/k given in Table 1 show that this ratio is in all cases substantially equal to the humid heat of the entering gas, which in this case was identical with the specific heat because the gas which was used was vapor free.

TABLE 1 VALUES OF h/k FOR VARIOUS VAPOR GAS MIXTURES

	h/k calculated from experimental results	Specific heat of gas
Water-air	0.236	0.238
Water carbon dioxide	0.217	0.220
Toluol air	0.238	0.238
Chlorbenzol air	0.218	0.238

We have therefore demonstrated that, granting substantial constancy of s and r_w, and assuming H to be small, the ratio of the coefficient of diffusion of heat to that of any vapor through the gas film on the surface of the liquid is equal to the "humid" heat of the gas. Furthermore, during "adiabatic"[1] evaporation of a liquid into a gas, the liquid being in dynamic equilibrium with the gas, the temperature of the liquid remains unchanged throughout the process and the end-point of the process is reached when the gas has cooled itself to saturation at a temperature identical with that of an ordinary wet-bulb thermometer.[2]

Importance of the Relationship $h/k = s$

The importance of the relationship $h/k = s$ is very great. The term s, the humid heat, may be readily calculated for any case, regardless of whether the problem is primarily one of heat transfer or of diffusion. Hence if the heat-transfer coefficient h has been experimentally determined for a certain type of apparatus operating under definite conditions, the coefficient of diffusion equals h/s, and the capacity of this same apparatus may be predicted when functioning in diffusion processes, e.g., as a gas scrubber. Conversely, if k and s are known for definite conditions, h equals ks; in other words, one can predict the performance of a given apparatus for heat transfer from data upon the same equipment functioning as a scrubber.

These processes of diffusion of heat and of vapor are at the basis of the performance of all such equipment as humidifiers, dehumidifiers, water coolers, gas scrubbers, air driers, light oil stripping columns, and the like. The above relationships make it possible to study the performance of such equipment on a more rational basis than hitherto and to compare the effectiveness of different types of equipment even when the data on the individual types are obtained under widely varying conditions. The Department of Chemical Engineering, Massachusetts Institute of Technology, expects to publish in the near future a series of articles showing various applications of these relations.

Occlusion of Gases in Coal

The great trouble about the analysis of coal and the estimates based upon the analysis is that the analytical processes themselves affect the coal so that the methods of examination are conventional. That concerns the very first quantity determined in any analysis, the moisture, and further, the volatile constituents and the occluded gases. The occluded gases can be determined by pumping off the gas liberated, or by collecting the gas given off in a vacuum, either at ordinary temperature (15 deg. cent. or lower) or at 100 deg. cent. Especially at ordinary temperature the experiments will last many days, and there is evidence that the first liberation of the gas will be followed and accompanied by a reabsorption, and that the establishment of an equilibrium condition will be a slow process depending, among other conditions, on the diffusion of gas from the inner layers up into the first-evacuated surface layers of the coal. Conducting such experiments upon various coals and lignites occurring in New Zealand, A. D. Monro of Canterbury College, Christchurch, found that some of the coals behaved peculiarly. There would be strong spasmodic outbursts of gas, e.g., on the 7th, 22nd, 31th and 36th day, the evolution of gas stopping almost entirely on the intervening days, while in other cases the gas evolution would be much more steady. While the percentage of CO_2 in the gas evolved changed little during the outbursts, the percentage of nitrogen and, to a lesser degree that of oxygen, varied very much. Nitrogen and oxygen generally came off first from the various coals, carbon dioxide and methane more slowly. Most of the methane was liberated only by heating; in mines methane is, of course, slowly evolved without external heating, but the coal may be under considerable pressure and at relatively high temperature *in situ*. Monro suggests that gases are both mechanically retained, and held in solution, probably at considerable pressure; the latter would be more important and would account for the spasmodic outbursts. (*Journal Society of Chemical Industry*, April 29, pp. 129–132T)

SURVEY OF ENGINEERING PROGRESS

A Review of Attainment in Mechanical Engineering and Related Fields

Properties of Steam at High Pressures

By G. EICHELBERG

INVESTIGATION into the values of the heat of vaporization of steam. In particular, the author attempts to establish a relation between the exponents in the adiabatic equation, the heat of vaporization, and the specific heats of the steam, and measure indirectly the specific heats of saturated steam by using this relation.

The recent attempts to employ commercially steam pressures of the order of [illegible] atmos. makes it important to consider the behavior of steam at these pressures. Unfortunately, steam tables fail to agree for pressures in excess of 20 atmos. Because of this it was suggested that the measurements as to the heat of vaporization carried out by the German Institution for Physical and Technical Measurements be extended into this region of values, and this was actually done by Schuele in 1921. The results obtained by him were very different from those previously secured by the present author. At about 20 atmos. there is a difference in the values of the heat of vaporization as found by the two investigators of about 6 large calories, and at about 40 atmos. the difference is 19 large calories. Corresponding differences would of course appear also in the values for saturation volumes of steam as these are connected by thermodynamic laws with the values for the heat of vaporization.

It is claimed, however, that the measurements of specific heat in the region of superheat which Schuele had available, extended only up to 8 atmos. On the other hand, Eichelberg bases his values on the Munich measurements of the specific heats of superheated steam. These values were expressed in the form of an equation from which the various magnitudes of state in the region of superheat could be derived, one after another, in accordance with well-known thermodynamic laws. Furthermore, by means of the equation for the specific heats of water (Knoblauch and Winkhaus) and the condition of equilibrium between steam and water, it became possible to obtain the curve of vapor tension and finally all the magnitudes of state in the region of saturation, in particular, the values of the heat of vaporization.

These latter in the region above 10 atmos. have shown material deviations from the values obtained by Schuele and only further experimentation can show which are correct. Meanwhile, and having regard to the measurement of the specific heats of steam, there are two ways to which to proceed in forming an opinion.

The first of these is based on the variation of the heat content in cases of high superheat and requires that at equal temperatures the heat content shall decrease with increase in pressure. Since the specific volume of steam is smaller than it should have been according to the gas law, but with increase of superheat approaches it asymptotically (in other words, since in the equation $v = \frac{RT}{p} - \Delta$ the member Δ has a negative sign and converges toward zero, so that $\Delta > 0$ and $\left(\frac{\partial \Delta}{\partial T}\right)_p < 0$, it follows that—

$$\left(\frac{\partial i}{\partial p}\right)_T = A\left[v - T\left(\frac{\partial v}{\partial T}\right)_p\right] = A\left[-\Delta + T\left(\frac{\partial \Delta}{\partial T}\right)_p\right] . [1]$$

is always negative.

But the heat content i of steam consists of the heat content i' of the liquid, the heat of vaporization r and the heat of superheat i'', and because of this the variation of r may be tested by taking into consideration the requirement that i must decrease at equal temperature with increase in pressure.

In Table 1 i has been computed for $t = 550$ deg. cent. as the sum of the three magnitudes above referred to with the Schuele values for the heat of vaporization. After a brief falling off in the value of i, it appears that from 6 atmos. up (Fig. 1) there is a rise in value, in contradiction to the condition established above. As the Eichelberg values are derived directly from an equation for i and the values of r are calculated therefrom, the contradiction (lines 5 and 6) does not appear in this case.

Up to 10 atmos. there are available satisfactory measurements of the heat of vaporization (Henning) expressed by an equation proposed by Thiesen (line 7). Within the range to which these measurements apply the three sets of values are in good accord. As it is unlikely that there is an error in i'', it follows that one of the two magnitudes is too large; namely, either the heat of vaporization r as found by Schuele, or the heat of superheat i_u at 20 atmos. the value of error being about four large calories.

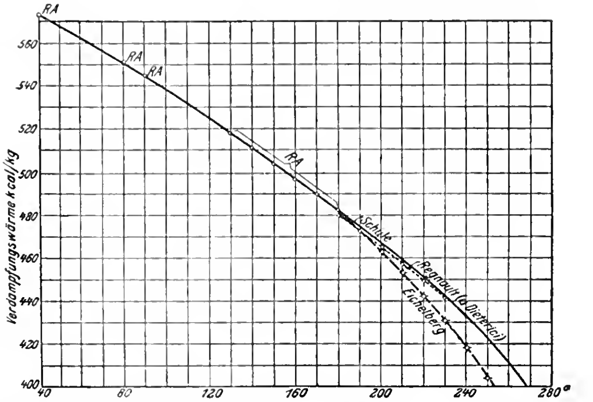

FIG. 1 HEATS OF VAPORIZATION (ORDINATES ARE HEATS OF VAPORIZATION IN LARGE CALORIES PER KILOGRAM; ABSCISSAS ARE TEMPERATURES IN DEG. CENT.)

To ascribe such an error to the value of the heat of superheat would mean, however, that the c_p curve for $p = 20$ atmos., which has been found by careful experiments, must be so displaced as to fall under the present curve for $p = 18$ atmos. without displacing at the same time the corresponding curve for $p = 8$ atmos. This again would mean that in the neighborhood of the limit of saturation the values for c_p at 20 atmos. must be located at least 10 per cent lower, somewhere as indicated by the broken line in Fig. 2. Notwithstanding the difficulty of measuring c_p, however, one would

TABLE 1 HEATS OF VAPORIZATION AND HEAT CONTENTS

p (atmospheres) =	2	4	6	8	10	12	14	16	18	20
1 Heat content of water i'	119.9	143.9	159.4	171.4	181.1	189.9	197.3	201.1	210.2	215.9
2 Heat of superheat i_u (550 deg. cent.)	211.0	202.6	197.8	194.5	192.0	190.4	188.9	187.8	187.0	186.5
3 Heat of vaporization r according to Schuele	525.7	508.7	498.0	489.7	482.6	476.9	471.4	466.6	461.8	457.4
4 Heat content at 550 deg. cent. with r according to Schuele	856.6	855.2	855.2	855.6	856.0	857.1	857.6	858.5	859.0	859.8
5 Heat content at 550 deg. cent. according to Eichelberg	856.8	856.4	856.0	855.6	855.2	854.9	854.5	854.1	853.7	853.3
6 Heat of vaporization r according to Eichelberg	525.9	509.9	498.8	489.7	481.8	474.7	468.3	462.2	456.5	450.9
7 Heat of vaporization r according to Thiesen	525.6	509.7	498.4	489.6	481.9	(475.3)	(469.2)	(463.7)	(458.6)	(453.8)

not expect to find such an error in the classical Munich measurements, which would lead to the belief that the Schuele heats of vaporization obtained by extrapolation based on insufficient experimental values are too high even for 20 atmos. In this connection the author states that Professor Knoblauch, one of those in charge of the Munich tests, assured him that it is inconceivable that the curve for 20 atmos. could, as shown in Fig. 2, be shifted so to appear below the curve for 18 atmos.

The second method of procedure mentioned by the author is of great interest, though not equally compelling. It is based on the slight variations (observed many times before) of the exponent of the adiabatic equation.

The exponent K_s = constant in the adiabatic equation $pv^K = C$ is

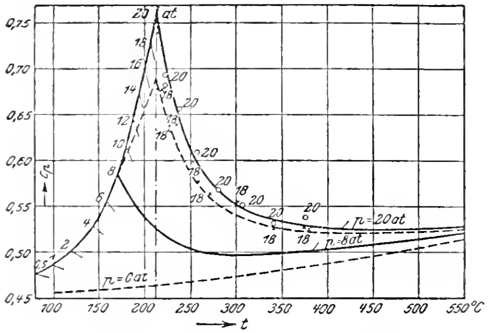

Fig. 2 Specific Heats c_p (At. = Atmospheres; Abscissas in Deg. Cent.)

the product of the exponent of the isothermal equation K_T = constant and the ratio c_p/c_v of the specific heats. It is identical with these latter only in the case of ideal gases, where $K_T = 1$. In the case of steam K_T beginning with the value 1 for $p = 0$, it decreases as we move along the limit of saturation, and at the critical point where $\left(\frac{\partial v}{\partial p}\right) = \infty$ it reaches the value—

$$K_T = -\frac{v}{p\left(\frac{\partial v}{\partial p}\right)_T} = 0$$

Since at the same point $\frac{c_p}{c_v} = \infty$, the value of K_T which it assumes at that critical point is indeterminate.

Numerical solution of the equation for c_p gives Table 2 and Fig. 3, which between them indicate that K_s has a nearly constant value of 1.3. This value has long been used for steam. A similar constancy of value has been observed with respect to the exponent n in the equation T = constant p^n, and this relation permits the following insight into the courses of variation of the heat of vaporization. From the relation

TABLE 2 EXPONENTS OF THE ISOTHERMAL AND ADIABATIC EQUATIONS (ALONG THE LIMIT OF SATURATION)

	K_T	$\frac{c_p}{c_v}$	K_s
$p = 2$	0.977	1.342	1.311
$p = 6$	0.947	1.382	1.310
$p = 10$	0.919	1.420	1.307
$p = 14$	0.891	1.466	1.305
$p = 20$	0.849	1.535	1.303

$$\frac{r}{T} = s'' - s' \qquad [2]$$

when

$$ds = \frac{c_p}{T}\,dT - A\left(\frac{\partial v}{\partial T}\right)_p dp \qquad [3]$$

it follows that

$$\frac{d\left(\frac{r}{T}\right)}{dT} = \frac{c_p}{T} - A\left(\frac{\partial v}{\partial T}\right)\frac{dp_s}{dT} - \frac{c_{fl}}{T} \qquad [4]$$

provided c_{fl} denotes the specific heat of water along the limit of saturation, and all the other magnitudes in the equation likewise refer to the limit of saturation. On the other hand, however, the exponent n may be expressed as follows:

$$n = \frac{Ap}{c_p}\left(\frac{\partial v}{\partial T}\right)_p \qquad [5]$$

If now, from Equations [4] and [5] we eliminate the expression $\left(\frac{\partial v}{\partial T}\right)_p$ which is difficult to determine, we obtain—

$$c_p'' = \frac{T\frac{d\left(\frac{r}{T}\right)}{dT} + c_{fl}}{1 - n\frac{T}{p}\frac{dp_s}{dT}} \qquad [6]$$

or

$$n = \left[1 - \frac{T\frac{d\left(\frac{r}{T}\right)}{dT} + c_{fl}}{c_p''}\right]\frac{1}{\frac{T}{p}\frac{dp_s}{dT}} \qquad [7]$$

In this thermodynamically well-founded equation the following

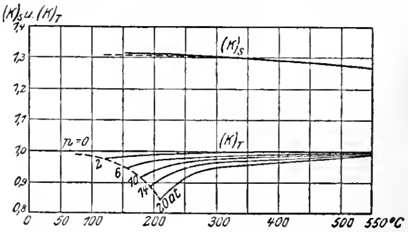

Fig. 3 Specific Heats c_p (At. = Atmospheres; Abscissas in Deg. Cent.)

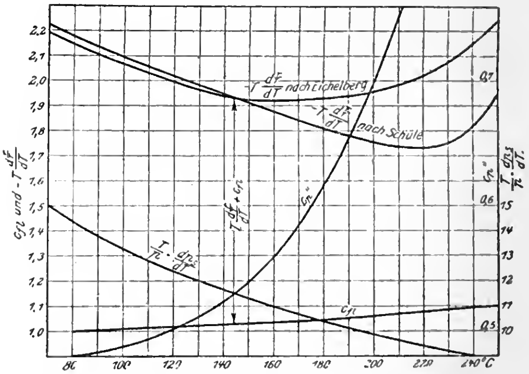

Fig. 4 Auxiliary Curves for Determining the Exponent n (*Und* = and; *nach* = according to.)

magnitudes may be considered as known with a great degree of reliability: $\frac{dp_s}{dT}$, the tangent of the steam-pressure curve up to the critical point; c_{fl}, the specific heat along the limit of liquefaction (up to about 300 deg. cent.), and likewise c_p'', the specific heat at constant pressure at the limit (up to 20 atmos.).

The magnitude $\frac{d\left(\frac{r}{T}\right)}{dT}$, or the inclination of the r curve, is subject to discussion, and with this in view the course of variation of n as found from Equation [7] may be examined.

Table 3 and Fig. 4 furnish the auxiliary magnitudes necessary to compute n; likewise from Fig. 4 the numerator $T\frac{d\left(\frac{r}{T}\right)}{dT} - c_{fl}$

TABLE 3 DETERMINATION OF EXPONENT n

	t_s (deg. cent.) =	80	100	120	140	160	180	200	210
1	c_p	1.00	1.01	1.02	1.02	1.03	1.05	1.06	1.07
2	c''_p	0.48	0.49	0.50	0.52	0.56	0.615	0.70	0.75
3	$\frac{T}{p}\,\frac{dp_s}{dT}$	14.4	13.3	12.4	11.7	11.0	10.4	9.9	9.65
4	$T\,\frac{d\left(\frac{r}{T}\right)}{dT}$ according to Eichelberg	−2.13	−2.07	−2.00	−1.94	−1.92	−1.93	−1.955	−1.98
5	$T\,\frac{d\left(\frac{r}{T}\right)}{dT}$ according to Schuele	−2.17	−2.09	−2.01	−1.94	−1.87	−1.80	−1.76	−1.73
6	Exponent n according to Eichelberg	0.236	0.237	0.238	0.237	0.235	0.234	0.231	0.229
7	Exponent n according to Schuele	0.239	0.240	0.240	0.237	0.227	0.214	0.202	0.195

may be read off as the distance between the two curves. The exponent n (lines 6 and 7 in Table 3) is plotted in Fig. 4 on a large scale. For purposes of comparison the exponent $\frac{K_s - 1}{K_s}$ as given by Table 2 is also plotted in broken lines.

The values of the exponent n computed by means of the values of r obtained by Eichelberg coincide on the whole with the $\frac{K_s - 1}{K_s}$ values, which was to be expected, as K_s and r are both derived from the same c_p equation. All the values of n lie between 0.23 and 0.24, which is in good agreement with the values determined by Hirn and Cazin in exhaust tests, namely, $n = 0.236$.

On the other hand, Schuele's values of r lead to an exponent which lies within the same limits up to 150 deg. cent., but which at 140 deg. deviates from the original direction and at about 210 deg. cent. (which corresponds to about 20 atmos.) falls under 0.200, which would correspond to an exponent $K_s = 1.25$. All observations on steam as well as other vapors would, however, indicate the possibility of only a slight variation of the exponent. If the exponent be assumed to have a value between 0.23 and 0.24 for pressures of the order of 20 atmos. and if this should be confirmed by test, it would be obviously necessary to recognize that values of r which give contradictory results are incorrect. Since Equation [7] appears to be rational, and the error cannot be looked for in the other magnitudes besides r involved in the equation, the same statement would apply for c_p'' with the indicated values of r: it would be incorrect to the extent of 0.2 large calories, or, say, 30 per cent.

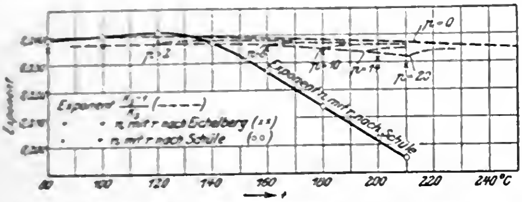

Fig. 5 Exponent n in the Adiabatic Equation $T = p^n$
(*mit r nach* = with the values of r as determined by.)

Finally, attention may be called to the fact that the comparatively sharp inflection in the course of variation of the heats of vaporization as shown in Fig. 4 is per se quite natural, as has been already recognized by Schuele. If, for purposes of comparison, one should plot the heats of vaporization r of various materials with the values of T/T_{crit} the curves obtained thereby would in many instances show an approximate proportionality. In Fig. 6 such a comparison is made for water, carbon dioxide, and ammonia. The latter two curves follow quite closely Eichelberg's r curve which, however, does not mean anything beyond proving once more that Eichelberg's r curve for steam has a rational basis. Such an analogy of curves, on the one hand, does not constitute a positive proof any more than does a comparison of the exponents of the adiabatic equations, at least so long as nothing more certain is known about these latter. On the other hand, however, according to the first criterion indicated above, it is certain that the values of the heat of vaporization extrapolated by Schuele are in conflict with the Munich measurements of specific heats of superheated steam between 10 and 20 atmos.

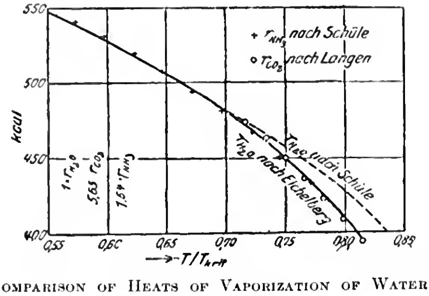

Fig. 6 Comparison of Heats of Vaporization of Water, Carbon Dioxide and Ammonia
(*K cal* = large calories; *nach* = according to.)

It would be very desirable to have this matter cleared up by further experiments. Much would be achieved if only the exponents of the adiabatic equation could be measured at 20 atmos. pressure and saturation, which could be done either by the Hirn and Cazin method or by measuring the velocity of sound in the corresponding medium. For the region above 20 atmos. the precise measurement of r would be of particular interest, together with the measurement of the exponent n or K_s, since then by means of Equation [6] one could obtain very reliable values of the specific heats c_p along the limiting curve which it has been impossible hitherto to obtain by any other method of measurement. Developments in Power-Station Design

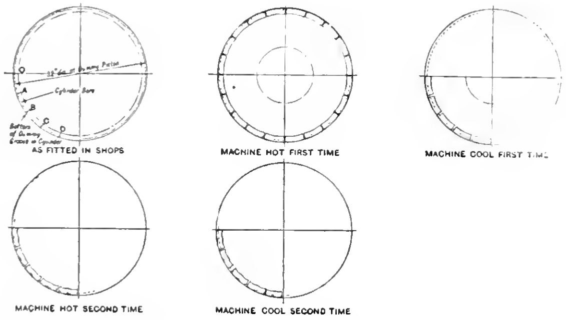
According to a report issued by the Electricity Commissioners (England), electric power is generated very cheaply in the north of England and the most economical steam generating station is that at Carville-on-Tyne. The design of this station involved the solutions of a number of new problems, because of the abnormal steam conditions chosen and a speed of 2400 r.p.m. with 10,000-kw. alternators, which at the time of the design of the station (1915) was unusual. The steam conditions specified were a steam pressure of 200 lb. per sq. in. at the stop valve and a total temperature of 650 deg. fahr. with the additional specification that the steam turbines should be capable of withstanding continuously a temperature of 700 deg. fahr.

The difficulties which had to be overcome in order to operate the turbines at an initial steam pressure of 650 deg. to 750 deg. fahr. were found to be due almost entirely to unequal heating and cooling when starting up and shutting down, and these difficulties were aggravated by the unequal coefficient of expansion of the materials used. On starting up a Parsons turbine from the cold condition, the shroud strip on the blading heats up more quickly than anything else and by its expansion spreads the blades fanwise, the greatest bending stresses being produced at the roots of the outermost blades of a segment or unit. On shutting down the machine, the shrouding strip cools down first, and owing to its contraction the blades are bent in the reverse direction. The greater the circumferential length of the blade segments, the more serious is the effect produced, and if this dilation is sufficiently great, ultimate fracture of the blades at the root is the inevitable result.

In the first of the five 10,000-kw. sets installed in the Carville station, "end-tightened" blade segments composed of manganese

copper and about 6 in. long were used in the high-pressure cast-steel cylinder. The difference in the coefficient of expansion between the dummy packing or the blading material and that of the cylinder and shaft led to trouble, and the sequence of events is shown in Fig. 1. The top left-hand diagram shows a ring of brass strip dummy packing originally calked in at the ordinary temperature of the surroundings in 6-in. segments. On starting up the turbine the brass expanded more than the casing, with the result that the strip was forced out of the groove at the weakest points, namely, at the butt joints *A*, *B*, *C*, etc., the effect being shown in the diagram, Fig. 1. On shutting down the turbine the brass strip cooled more rapidly than the casing, and owing to the larger coefficient of expansion contracted to a greater extent, and definite gaps were left between the segments, as shown in the third diagram. The next time the turbine was started, however, the brass strip again heated up first and expanded more than the casing, and appeared to become so firmly wedged in the grooves that free expansion was restricted, with the result that hogging took place in the middle of the segments, as shown in the bottom left-hand diagram; while on cooling down the brass strip contracted freely and the gaps were widened still more, as shown in the next diagram.



AS FITTED IN SHOPS MACHINE HOT FIRST TIME MACHINE COOL FIRST TIME

MACHINE HOT SECOND TIME MACHINE COOL SECOND TIME

Fig. 1 Diagram Showing the Effects of Heating and Cooling in Steam Turbines

The ultimate effect of these results was the formation of large gaps between the segments, creeping of the segments in their grooves, so that in some cases they were butted close together with a corresponding large gap elsewhere, and general displacement out of the grooves. The cylinder blading behaved in a similar manner, while in the case of the rotating blade rings on the shaft the butted ends of the segments were forced outward, and the blades at the ends became loose. All these troubles were, however, largely overcome by the simple expedient of inserting both blade units and dummy packing strips in short lengths. In the case of the blading the segments were made about $1^1/_2$ times the length of the blades and they were also brazed up solid at the roots, which were accurately faced at the ends, so that creeping was made impossible. The shrouding strip was kept the same length as the blade units, but small gaps were left between adjacent pieces. Dummy piston-packing strip was inserted in lengths of about 1 in., and proved to be entirely satisfactory. During the construction of the later machines for the Carville station further improvements were made.

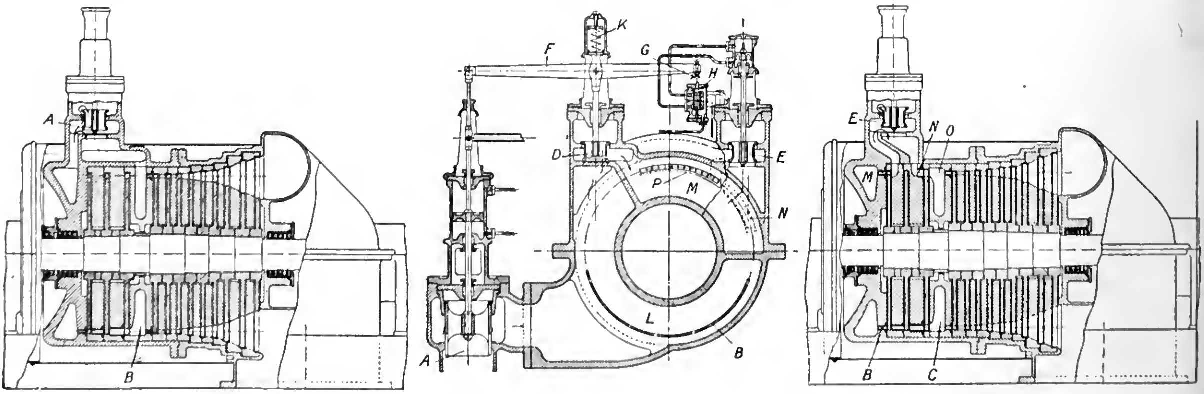


Fig. 2 Original Type of Oerlikon Turbine, and Fig. 3, New Type of Oerlikon Turbine

Steel blade material was adopted, and the individual "lock root" type of blading was introduced into the shafts, each blade unit consisting of a blade and spacing section riveted and brazed together, the root being heavily serrated on both sides. The blade units were then assembled in grooves with parallel sides and with correspondingly heavy serrations, the last blades of each row being inserted through a lantern space, which was finally closed by a serrated steel locking piece calked in position with copper calking pieces. After being assembled into a complete blade ring in the shaft, the shroud strip was brazed on to the blade tenons in short lengths, the adjacent ends slightly overlapping so that in service flexibility is permitted without increasing the steam-leakage area. In the latest Parsons turbines the blade units are produced in one piece, a blade root and a spacing section being combined by a special process which does not involve expensive milling out of the solid nor casting the blades into the roots. The experience obtained at Carville has enabled perfect "end-tightened" reaction blading to be produced, and it is claimed to be quite suitable for the high steam temperatures which are now coming into use.

The success of the first Carville unit was such that several other similar sets were built. Recently two 10,000-kw. tandem machines of similar design, but without water-cooled rotors, and running at 3000 r.p.m. were installed and are run under the same steam conditions as those at Carville, and several other sets are either being installed or are under construction. It is of interest to note that while originally the specified steam temperature was 650 deg. fahr., this temperature was subsequently increased to 706 deg. fahr. owing to the efficiency of the superheaters and the absence of trouble with the turbines. The turbines are of the Parsons type.

The experience with these turbines has shown that when the electrical conditions permit, it is now easier and better to build a 15,000-kw. set for 3000 r.p.m. than for 1500 r.p.m.

One of the most recent turbine improvements is due to the Oerlikon Company, which has introduced a special method of admitting extra steam during times of overload. Steam turbines are usually required to deal with an overload of, say, 25 per cent for a specified period, which may range from one-half to two hours, and, generally speaking, the steam consumption while this overload is being carried exceeds that which is experienced while the machine is running at the normal full load for which it has been designed. The method of admitting the additional steam varies to a great extent in different makes of turbines. In the Oerlikon turbine, which has pressure stages, it was originally customary to introduce the overload steam into the second or one of the following stages, as shown in Fig. 2. Steam passed from the steam chest through the high-pressure section into the intermediate steam chamber

B, and from there into the low-pressure portion of the turbine, where there is full peripheral admission; while in the high-pressure portion there is only partial admission. At all loads up to full load the overload valve *A* remains closed, but when the load exceeds the full normal value the valve opens and admits steam to the low-pressure portion. A table is given in the paper which shows the increase in the steam consumption under overload conditions.

With the boiler plant available it was not possible to maintain the same steam conditions at all loads, the temperature of the steam in both the tests being higher during the overload tests than it was when the machines were running at other loads; but in arriving at the percentage increases given due allowance was made for that fact. Up to full load the steam consumption per kilowatt-hour decreases as the load increases, but after full load has been reached the consumption rises. Similarly, the efficiency of the turbo-generator increases up to full load and drops on overload. The steam consumption on overload is not of great importance when the overloads are infrequent and are of short duration, but in view of the fluctuations of load on the supply system, a turbine of the type shown—Fig. 2—would not, the makers contend, usually be worked at full load, as the variations in the load on the system would involve the by-pass valve being opened at fairly frequent intervals. Variations in steam pressure and vacuum have also to be taken into account, and the normal load under working conditions would hardly exceed 90 per cent of the full load. With the Oerlikon Company's patented arrangement for the admission of steam into turbines, however, the heat drop during the overload period can be entirely utilized. The steam passes from the main inlet valve into the throttle valve *A*—see Fig. 3—and the quantity of steam admitted to the turbine varies according to the load. The steam chest, as the drawing shows, occupies only a portion of the circumference, and the bank of nozzles *B* is designed to deal with the quantity of steam which the turbine requires for full load. This steam passes through the high-pressure part of the machine, which consists of three pressure stages, and flows into the intermediate steam chamber *C*, and from there into the low-pressure wheels, where there is full peripheral admission; while in the high-pressure part there is only partial admission. In the first and third stage of the turbine there is a separate bank of nozzles for the passage of the overload steam. As soon as the turbine is subjected to an overload and the normal supply of steam is no longer sufficient to enable the turbine to develop the output required, the two overload valves *D* and *E* open automatically. The central lever *F*, which is fitted with an adjustable screw *G*, opens the valve *E* by pressing on a pilot valve *H*, which causes the valve *E* to open by supplying oil under pressure to a piston. When the pilot valve has reached its lowest position the control lever *F* pivots about the screw *G*, and the overload valve *D*, which is normally held down by the spring *K*, is lifted. The additional steam passes from the steam chest *L* through the valve *D* into the steam chamber *M*, and from there it passes into the nozzle segments *P* and into the first turbine wheel. It is then led through the overload valve *E* to the nozzle segments *N* in the third stage of the turbine, and from there into the third set of wheels, where its energy is utilized. In the intermediate chamber *O* it joins the main supply of steam and flows through the low-pressure portion of the turbine.

The results obtained with this system of supplying extra overload steam to turbines have met all expectations. The fundamental difference between the old and new arrangements lies in the fact that in the latter case the efficiency steadily rises up to an overload of 140 per cent. Tests made on a 1500-kw. machine have also confirmed this result, and with this new arrangement for admitting overload steam it is not only possible to run the turbine at its full capacity, but also run it at overload for the full period as determined by the heating of the generator. In the case of back-pressure turbines working on overload the advantages of the new system of admitting overload steam are even greater than those which are obtained when the system is applied to ordinary turbines, as the total heat drop is smaller. All the Oerlikon turbines are now provided with this improved arrangement, and some of them are coupled to generators which are capable of carrying the overload continuously. (Serial article in *The Engineer*, vol. 133, no. 3459, Apr. 14, 1922, pp. 406–409, illustrated, *dgA*)

Short Abstracts of the Month

CONVEYING MACHINERY

Steel-Band Conveyors. Description of steel-band conveyors of the rolled linkless type as built by a German concern (Sandviken). This band is very thin (0.8 to 0.9 mm. or 0.031 to 0.035 in.) and consequently flexible. At the same time it is sufficiently stiff laterally to permit of spreading the material over a great width. The surface of the band is hardened to reduce wear. The end sheaves and supporting rollers may be made smaller than the width of the band; hence they may be made of large diameter, thus reducing the cost and power consumption.

The upper working strand of the band may be guided either on rollers or on slides. The lower strand is always supported on rollers. Graphite is usually used as a lubricant. Some data as to design are given in the original article. As regards drive, the steel-band conveyor does not essentially differ from other types. The speed of the band may vary from 60 to 90 m. (196 to 295 ft.) per min., depending upon the capacity.

It is claimed that such a steel band does not easily rust and that it is suitable for transport of wet material, such as clay, beet-root shavings, pulp, etc. When such sticky material is handled a special band cleaner is suspended above the lower strand near the end sheaf, pressing against the latter by means of springs. The original article illustrates the charging arrangements and also a unit used in a steel plant for transporting granulated blast-furnace slag and ore. Synthetic and Electric-Furnace Cast Iron

Electric Cast Iron. Abstracts of four papers presented at a meeting of the American Electrochemical Society in Baltimore, April 27, 1922, and which cover the historical, economic, metallurgical and "sane" phases of the subject.

Geo. K. Elliott presented a paper on Cast Iron as Produced in Electric Furnaces. The first use of the electric furnace for gray cast iron in regular production seems to have been made by the Lunkenheimer Co., Cincinnati, Ohio, in the summer of 1917, the cupola being utilized in the melting period and the electric furnaces for refining.

The primary factor justifying the employment of the electric furnace as the second step in a duplexing process lies in its ability to refine and superheat the metal, two things which cannot be done in the cupola. On cast iron the electric furnace is capable of delivering without too great attention metal superheated to any degree, reduced in sulphur as required, deoxidized, and with carbon, silicon and manganese adjusted to the desired standards (this applies especially to the furnace with basic bottom). Phosphorus cannot be altered in cast iron by the electric furnace in commercial practice. The electric furnace is at its best when coupled with the chemical laboratory in an intimate manner.

The advantages of superheating lie in the increased fluidity of the iron. Greater fluidity not only permits the use of low-phosphorus iron, but in other metals assures solid castings through freedom from blow holes, shrink holes, slag inclusions and the like. Superheated metal increases the effectiveness of risers by lengthening the period of fluidity, which is their only period of activity as feeders, and thereby obviates to a large degree the internal shrinkage that comes from fluid contraction of the metal. Abetted by superhot metal the efficiency of the ordinary riser becomes surprising.

Jas. L. Cawthorn in a paper on Synthetic Cast Iron discussed methods of production of cast iron from machine-shop scrap. He stated that when this is melted in either an acid or basic electric furnace with 75 lb. of good coke per ton, it will come down with about 2.5 per cent carbon and well deoxidized. Melting under a carbide slag in a basic furnace does not change the carbon, man-

ganese or phosphorus, but reduces silicon practically to zero and sulphur to half. Acid-furnace melting without special slag, which is cheaper and simpler, brings down metal unchanged in sulphur and phosphorus; about 50 per cent of the manganese goes out in the slag and a little silicon may be picked up from the lining. If more carbon is needed it can be added by stirring it into hot, clean metal; for example, by poling, and the author described a useful test depending on the hardness of the test bar.

W. E. Moore gave a paper on History of Electric Cast-Iron Melting. The paper is, however, a good deal broader than its title.

It is stated that electric iron can be kept uniform in hardness and strength and under exact control for the particular application desired. The iron runs 50 to 90 per cent stronger than either cupola gray-iron castings or air-furnace malleable castings. Further, since electric iron may be rendered fluid by superheat, it is unnecessary to keep the phosphorus content high, low phosphorus adding to the resistance of the castings to shock.

In a case where the most careful cupola practice made bottle-machine molds which would hold their polish for four hours only, similar electric-furnace iron molds lasted from three to four times as long.

Table 1 was presented as giving the operating costs of iron furnaces. The figures of this table were, however, seriously questioned in the discussion. The electric furnace is said to offer superior metal for making white-iron castings to be malleableized or for making chilled castings, such as crusher wearing plates, chilled wheels, chilled rolls, etc. For electric iron castings charcoal pig may be eliminated entirely, with better results than before.

TABLE 1 OPERATING COSTS OF IRON FURNACES

	Cupola melting		3-Ton leectric furnace
Borings, 1500 lb. at $4			$ 3 00
Foundry pig, 1000 lb. at $20	$10.00		
Machinery scrap, 1000 lb. at $14	7.00	500 lb.	3.50
Per ton mixture average	$17.00		6 50
Melting loss, 8 per cent	1.36	4 per cent	0.68
	18.36		7.18
Coke, 1/6 ton at $8	1.33	50 lb.	0.20
Blower power and slags	0.50		
Additions			0.20
Power, 400 kw-hr. at 1½ cents per kw-br.			6.00
Electrodes, 10 lb. carbon at 6.5 cents			0.66
Refractory repairs	0.50		0.20
Labor	1.25		0.80
Total cost of iron "at spout"	$21.94		$15.24

In a paper entitled Synthetic and Electric Pig Iron Sanely Considered, Robt. Turnbull claimed that the manufacture of synthetic pig iron is a logical operation for iron foundries having electric furnaces and making either gray-iron or steel castings. In countries where coke is expensive, pig iron from scrap in an electric furnace may prove cheaper than electric-furnace production from ore.

The question of cost of production of cast iron in an electric furnace raised a lively discussion. E. L. Crosby told of a foundry in Detroit which could buy borings at $8 per ton and use them for 100 per cent of the charge. The current consumption was 600 kw-hr. per ton under eight-hour operation, or 500 to 525 kw-hr. per ton for sixteen-hour operation. With current at 1.8 cents per kilowatt-hour, molten iron from borings cost $23.60 per ton, whereas cupola iron made right alongside cost $25.00 per ton, the number of rejections of castings being far less with electric iron than with cupola iron. On the other hand, the claim put forward by W. E. Moore that electric iron can be made at $15 per ton was vigorously opposed by several speakers.

As part of the discussion Dr. Richard Moldenke read a translated abstract of an article from a German publication (*Giesserei-Zeitung*) describing the practice of a German foundry using the cupola-electric furnace duplexing process, and giving an itemized cost of operation in German units. (American Electrochemical Society papers abstracted through *The Iron Age*, vol. 109, no. 18, pp. 1203–1205, and *Chemical and Metallurgical Engineering*, vol. 26, no. 18, pp. 820–822, *gc*)

Cobalt-Tungsten Alloys, Karl Kreitz. Data of extensive experiments with alloys of these two metals, as a result of which experiments it was found that the alloys may be divided into five groups as follows: Those containing up to 40 per cent of tungsten have a mixed crystal structure; from 40 to 45 per cent tungsten, a eutectic matrix with primary mixed crystals; from 45 to 70 per cent tungsten the mixed crystals disappear and the crystals of a cobalt-tungsten combination take their place; from 70 to 80 per cent tungsten the alloys have an unstable structure, indicating the appearance of excess of tungsten; finally, alloys containing more than 80 per cent of tungsten, consisting of a homogeneous matrix embodying primary crystals, or possibly mixed crystals with a high content of tungsten.

From the investigation it would appear that only alloys containing about 10 per cent of tungsten may have a practical importance, for example, for use as a material for metal-cutting tools. The Brinell hardness varied from 185 to 282 with the increase of tungsten from 0 to 97 per cent, the variation being quite gradual. On the other hand, however, the increase of tungsten reduced the ability of the alloy to resist corrosion when in contact with sea water. (*Metall und Erz*, vol. 19, no. 6, Mar. 22, 1922, pp. 137–140, 1 fig., *e*).

Y Alloy (Aluminum-Copper-Nickel-Magnesium). Data on an alloy described in a recent report to the Alloys Research Committee of the British Institution of Mechanical Engineers, entitled Some Alloys of Aluminum.

The alloy contains about 4 per cent copper, 2 per cent nickel, 1.5 per cent magnesium and remainder aluminum. When properly cast and heat-treated it has a strength of 47,000 lb. per sq. in., and when rolled and heat-treated 54,500 lb. per sq. in., with an elongation of 24 per cent in 2 in.

The original article gives instructions as to the casting of this alloy. Its physical properties may be materially improved by heat treating. Chill castings are given a 6-hr. anneal at 530 deg. cent., then quenched in boiling water and aged. This treatment increases the tensile strength from 28,000 lb. to about 47,000 lb. per sq. in. with 6.5 per cent elongation in 2 in.

Data on correct forging and rolling practice and physical properties of rolled Y alloy after heat treatment are given in the original article. One of the remarkable properties of this alloy is its great resistance to corrosion, which is greater than that of high-strength aluminum alloys. (*Chemical and Metallurgical Engineering*, vol. 26, no. 17, Apr. 26, 1922, pp. 785–787, 6 figs., *de*)

FOUNDRY

Making Castings Without Feeding Heads. Abstracts of two articles, one in a British and the other an American publication. The first article reports the work of E. Ronceray, a French foundryman, who delivered a lecture at a meeting of the London section of the Institute of British Foundrymen, April 16, 1922.

The principle involved in the pouring of castings by this method is to run them from their thinnest section, so that the metal will freeze almost simultaneously throughout the mass of the casting, and to run the metal at such a rate that freezing will take place within as short a time as possible after the completion of the pour, thus reducing to the practical minimum the amount of liquid contraction in the period after the mold has been poured. By these means a casting can be poured with a runner or runners of relatively extremely small area, the total weight of the metal not employed in the actual casting being reduced to an almost insignificant amount compared with the weight of the casting. With the rate of pouring thus controlled, the metal first poured, as it cools and contracts, is said to feed itself from the metal poured afterward while pouring is still in progress.

It is claimed that with this method of casting not only a greater part of the melting scrap is eliminated but also sounder castings and a smaller proportion of wasters is produced. (*The Metal Industry* (London), vol. 20, no. 18, May 5, 1922, p. 417, *dp*)

Another instance of casting without a riser is described from American practice, with reference to the experience of the author in 1916 in connection with casting copper bands in sand. After some trouble a successful attempt was made to cast large copper bands weighing 30 lb. with a gate weighing only 1.75 lb. without using either risers or chills. The bands cast by this system are said to be clean and solid. To do this the copper was poled till brought to a good tough pitch. It was then poured at about 2500 deg. fahr. and just hot enough so that the head would not swell. At another time

similar castings were made by the author of 98 per cent copper and 2 per cent nickel mixture in sand without risers or chills. (Casting Copper Without a Riser, by Nelson F. Flanagan, *The Metal Industry* (New York), vol. 20, no. 5, May 1922, p. 182, 1 fig., *dp*)

HYDRAULICS (See Pumps)

INTERNAL-COMBUSTION ENGINEERING

Schuele's Tests of a Holzwarth Gas Turbine

Thyssen-Holzwarth Oil and Gas Turbines, Prof. W. Schuele. Tests made by Professor Schuele with the Holzwarth gas and oil turbine have led him to the conclusion that so far only that turbine satisfies the conditions imposed by the operating functions and work in modern plants. It is claimed that a thermodynamic efficiency of 45 per cent is attained with the Holzwarth process at a compression ratio of three as against a ratio of twelve in the piston gas engine. It is really the efficiency of compression that goes far to determine the comparative overall efficiencies of the gas turbine and reciprocating engine.

Another important consideration is the temperature condition in the unit. In the Holzwarth turbine the time during which the high temperatures prevail is short and is followed by a period of low temperature, which makes the Holzwarth explosion turbine as safe as a piston engine. It is said that the combustion turbine cannot operate without this rhythmical change of temperatures.

As compared with the steam turbine the gas turbine is remarkable from the fact that it requires but one stage for its drop of pressure from 230 lb. to atmospheric pressure, a ratio of sixteen. In the steam turbine the jet works uniformly, while in explosion turbines it works like a shot with decreasing jet velocity. Fortunately, this does not matter much, as is shown by Figs. 1 and 2. In Fig. 1 *BHC* represents the *p*-*v* diagram of the Holzwarth turbine working with a compression pressure of 2.2 atmos. and an explosion pressure of 17.3 atmos. abs. While the pressure decreases during the expansion from 17.3 atmos. abs. to 7.3 atmos. abs., the part of the energy marked with vertical lines has been transformed into kinetic energy and only the small balance below *MN* is left.

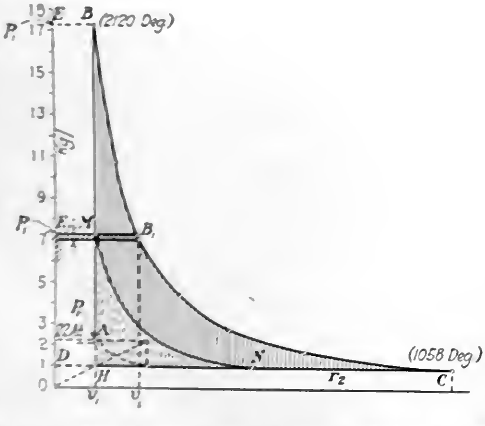

Fig. 1 Pressure-Volume Diagram of the Holzwarth Explosion Turbine

Fig. 2 shows that the jet velocity decreases slowly until about 90 per cent of the total energy is transformed into kinetic energy. During transformation of the last 10 per cent, however, which is not of much importance, the jet velocity decreases at a more rapid rate, and the efficiency of the one-stage turbine is therefore not much lower than that of a similar steam-turbine wheel. The shocks which the wheel blades have to stand in the Holzwarth turbine are, of course, much greater than with steam turbines.

Schuele made tests with a vertical 1000-hp. experimental gas turbine and found an efficiency of 25 per cent with the engine developing 1200 hp.

In this connection attention may be called to an article entitled Thermodynamic Bases for Determining Efficiency to be Expected from Gas Turbines, by H. Schmolke, abstracted from a German publication in Mechanical Engineering, March, 1922, pp. 187–190. This article is also largely based on the experience with the Holzwarth turbine and tests of Prof. Schuele. (Chapter from a German book translated by Hans Holzwarth, the inventor of the turbine, and published in *Motorship*, vol. 7, no. 5, May, 1922, pp. 351–53, 9 figs., *d*)

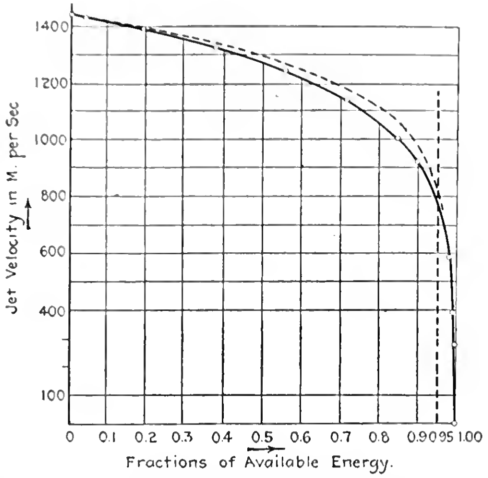

Fig. 2 Variation of Jet Velocity in the Holzwarth Explosion Turbine

MACHINE DESIGN AND PARTS (See Power Transmission)

MACHINE TOOLS

Abbreviations for Machine Designers

Methods of Machine-Tool Design, A. L. De Leeuw, Mem. Am.Soc.M.E. Among the things discussed in this article are a set of symbols (Fig. 4) which the author used as a sort of designer's shorthand. They are merely simplified, one might say skeletonized, indications of various machine parts and might be useful for preliminary sketches. Fig. 3 shows an arrangement of a gear mechanism represented by means of these symbols. There is a pulley with friction clutch, the clutch being keyed to a shaft. To this same shaft is keyed a pair of sliding gears which can mesh with two stationary gears on another shaft, and to this second shaft is keyed a bevel gear driving another bevel gear on a third shaft on which is keyed a worm driving a worm wheel. (*American Machinist*, vol. 56, no. 17, Apr. 27, 1922, pp. 617–620, 3 figs., *p*)

MARINE ENGINEERING

Voyage Around the World of Motorship "William Penn." On March 19 the *William Penn* completed her maiden voyage around the world of 28,500 miles. She is the first large American motorship suitable for deep-sea cargo trade. On her return to New York the propelling machinery was found to be in perfect condition, requiring no repairs. The exhaust and inlet valves of the main engines were changed only once, which was at the middle of the voyage. All work on the main engines was done by the engineer personnel when in port and all similar work on the auxiliary engines and machinery was done while under way at sea. There was no involuntary stopping of the vessel at any time throughout the voyage.

The two main engines are six-cylinder, $29^1/_8$ in. by $45^1/_4$ in. They were originally designed to run at 115 r.p.m. and deliver together 4500 i.hp., but because of the full form of the *William Penn* the power was cut down by reducing the revolutions to 108, corresponding to an output of 4200 i.hp. and a speed of 11.5 knots. In addition there are three auxiliary Diesel engines each direct-coupled to a 65-kw. generator for supplying current to the various electrically driven engine-room and deck machinery. At sea only one of the auxiliary engines was required and carried a load of about 55 kw.

The mean sea speed from New York to London was 11.01 knots with a mean fuel consumption of 13.06 tons per day (exclusive of donkey boiler). The longest non-stop run was from Singapore to Suez, 4943 nautical miles, taking nearly 18 days with a mean sea speed of 11.48 knots and mean total consumption of main and auxiliary engines of 13.41 tons per day, equivalent to a consumption per indicated horsepower of 0.3025 lb.

The original article gives a comparison between the *William Penn* and the electrically driven ship *Eclipse*, which, while not entirely strict, appears to be in favor of the motorship. It is also pointed out that there are several sister ships of the *William Penn* equipped with either steam turbines or reciprocating engines which have been laid up for the past year or more due to their inability to operate at a profit, while the *William Penn* sailed in April for the Far East again, carrying chiefly heavy or dead-weight cargo consisting mostly of structural steel and loaded down to the full-draft marks. With this class of cargo she is able to carry about 1000 tons more than an equivalent steamer, this amount representing the additional fuel and fresh water which the steamer has to carry.

On the way out the vessel encountered severe storms, and it became necessary to slow down to prevent losing the deck cargo. On the return trip the vessel was not fully loaded, although the cargo was of a bulky nature, consisting of hemp, copra, rattans, tapioca, coffee, etc. (*Marine Engineering and Shipping Age*, vol. 27, no. 5, May, 1922, pp. 313–314, 1 fig., *dc*)

MEASURING INSTRUMENTS

The Rotameter. Description of a new device for measuring the rate of flow of any gas or liquid through a pipe per unit of time. This device, the rotameter, consists essentially of a vertical transparent tube with a bore tapering toward the lower end and within which there is a circular, top-shaped float. The stream of gas or liquid flowing through the tube lifts this float, and the quantity passing through is directly read from an accurately calibrated scale fixed to or engraved on the tube. The accuracy of the apparatus lies in the peculiar construction of the float which is kept in rapid rotation by the steam of gas or liquid flowing past it. The float does not touch the walls of the tube and the instrument is assumed to be frictionless. The rotational movement of the float is much more sensitive to disturbance than the vertical movement and there is a continuous check upon the accuracy and proper functioning of the instrument. After long use the float and tube may become fouled and when a certain degree of fouling is reached the float will cease to rotate, thus giving warning that the instrument requires cleaning. It is stated, however, that the rotation ceases long before the accuracy of the vertical motion of the float, and consequently of the readings, is appreciably affected. (*Iron and Coal Trades Review*, vol. 104, no. 2826, Apr. 28, 1922, p. 612, 1 fig., *d*)

POWER-PLANT ENGINEERING (See also Railroad Engineering)

British Steam-Turbine Drive for Textile Mills

A Steam-Turbine Mechanical Drive for Textile Mills. Description of a unit designed by the Metropolitan-Vickers Electrical Co., Ltd., Manchester, England. The intention is to employ machines in sizes varying from about 800 to 2000 b.hp., which is a range that should cover the requirements of textile mills. The condenser is located immediately below the turbine exhaust, but the height from basement to ceiling is only 15 ft.

As regards efficiencies, it is stated that for a turbine of 1500 hp. the makers are prepared to guarantee that the steam consumption will not exceed 10 lb. per b.hp-hr. with steam at 180 lb. pressure, superheated 180 deg. fahr. and a vacuum of 28.5 in. This is equivalent to, say, 9 lb. per i.hp-hr. for a steam engine.

The condenser pumps are to be driven by ropes from the main turbine and a small steam engine is provided for driving them until the turbine is up to speed, after which the engine is cut out by means of a clutch. Where electricity is available for starting purposes, a small motor could be used instead of the steam engine.

Where there is a demand for steam at a pressure of 20 or 30 lb. for heating, drying, boiling, etc., the use of a turbine is economical as it takes very little more heat to raise steam to a pressure of 180 lb. than it does to raise low-pressure steam to 30 or even 60 lb. for heating. On the other hand, steam in expanding from 180 lb. to, say, 30 lb. can be made to do a great deal of useful work in passing through the turbine.

Where the whole of the exhaust from the turbine can be utilized irrespective of the load on the generator, a back-pressure turbine is usually installed; but the instances in which this type of turbine can be employed are limited, since it generally happens that the demand for heating steam is irregular and does not coincide with the demand for power. In other words, whereas with a back-pressure turbine there is a direct connection between the amount of steam available for heating purposes and the work which can be done by the turbine, there are other and more numerous schemes of power plant in regard to which the amount of power required and the demand for heating steam bear no relation to each other. A turbine is therefore required which will give either heating steam or electric power independently, and as the demand for either varies. These requirements are met by the reducing-pressure turbine, which consists of a back-pressure turbine and a low-pressure turbine arranged within one casing and having one shaft. The chief merit of this combination is that it possesses the advantages of an ordinary high-pressure turbine, in that low-pressure stages are provided, through which all surplus steam which has not been discharged into the heating mains can be economically expanded to condenser pressure.

It is of the utmost importance from the point of view of economy that the heating-steam pressure to be maintained by the turbine should be reduced to the minimum pressure which will suffice for the particular heating process under consideration. In the great majority of heating schemes the important point to bear in mind is that the energy dissipated in the process of heating is derived from the latent heat of the steam and not from the sensible heat. When this principle is grasped it will be seen that the back pressure against which the turbine is required to work should be as little as possible above the pressure which corresponds to the temperature required at the point where heating takes place. The loss of energy—and, therefore, of fuel—which results from raising the pressure in the heating mains above the necessary minimum is out of all proportion to any small increase obtained in the heating capacity of the steam.

The article compares the steam turbine and the reciprocating steam engine from several viewpoints, such as steam consumption, mechanical losses, radiation losses, etc., the comparison being on the whole in favor of the steam turbine.

A typical Metropolitan-Vickers reducing-pressure turbine is shown in diagrammatic form in the original article. In this illustration the steam chest and valve gear are shown attached to the top half of the cylinder. This is merely for the sake of facilitating an inspection of their functions. (*Mechanical World*, vol. 71, no. 1843, Apr. 28, 1922, pp. 307–309, 4 figs., *dc*)

POWER TRANSMISSION

Causes of Vibration and Chattering in Geared Drives

Nodal Arrangement of Geared Drives, Dr. J. H. Smith. In power-transmission systems consisting of shafts and toothed wheels it was often found that the gearing chattered. With the introduction of gear wheels running at high speeds the chattering conditions became very pronounced in certain cases. In certain motor cars there are ranges of speed in which it is impossible to secure quiet running without the aid of special appliances; in electric tram-car systems the phenomenon of rail corrugation appears and leads to serious trouble, but the most serious trouble is met with in the geared drives of turbine-propelled ships. The difference in the three cases apparently arises from the difference in size of the rotating masses employed.

Conditions are often particularly bad in double-reduction-gear systems. Occasionally a double-geared ship is produced which appears to give complete satisfaction, while occasionally a roarer is turned out which is found to be unsatisfactory even at half speed.

Various methods have been suggested for the reduction or elimination of chattering and its concomitant phenomena, such as increase in the amount of oil; reduction in pitch of teeth; shortening or lengthening of teeth; increase in the width of the teeth; and finally, adding flywheels and elastic couplings at various points of the drive. The author attempted to carry out a more or less complete mathematical investigation of the causes that led to the chattering. It is believed that the results of this investigation will point out the only possible solution of the problem.

The mathematical part of the paper is not suitable for abstracting and only some of the conclusions arrived at can be reported here.

In the first place, the author established the fact that there is a certain critical speed and defines it as a speed of revolution such that the amplitude of the fluctuating tooth-pressure torque is equal to the transmitted torque. At this speed parting of the teeth will occur. As the speed of the drive is gradually increased, the external periodic action will gradually search out the critical speeds of the system, and if any continuous running is allowed at any one of these synchronizing conditions, dangerous oscillations and chattering may occur. If the equation defining these conditions has (as it may have) a large number of roots lying within the range of the speeds of revolution of the various shafts, there will be a large number of critical speeds.

From a further investigation of the subject the author arrives at the conclusion that the effect of adding either a single mass or an elastic connection to a simple system of gears will increase the number of degrees of freedom of the system, and hence increase greatly the number of critical speeds.

In investigating the effect of tooth-form irregularities it is found that the searching periodic irregularities may be looked upon as a series of fundamentals for frequencies equal to the speeds of various shafts corresponding to inaccuracy in the centering of the wheels, together with a series of harmonics which it would be rather difficult to define, but which, in the upper limit, have periodicities corresponding to the number of contacts per minute. The author states that he knows of the case of a periodic variation in the thickness of the teeth every twelve teeth in a newly cut primary wheel. Periodic variations of tooth thickness are often observed in the worn gear wheels of motor cars.

It does not seem feasible at present to determine analytically the critical speeds arising from irregularities of teeth, as we have no information on the values of these periodic irregularities. If the degree of accuracy of gear cutting were known, the problem could be solved in the same way as that employed by the author for the effect of periodic torques. As this cannot be done, he attempts to solve it in a different way, and comes to the following statement of conditions best adapted for avoidance of the critical speeds which may arise from high-periodicity irregularities of the teeth of gear wheels in elastic-shaft geared drives.

The shafts must be made as flexible as possible and the ratio of the moment of inertia of the mass attached to any shaft to its attendant wheel must be as large as possible.

In the case of the low-periodicity irregularities arising from

varieties of pitch, inaccuracy of centering, etc., the only possible means of avoiding critical speeds may be stated as follows:

The system adopted must be such that it possesses the least number of possible free vibrations and the periodicity of these free vibrations must be as low as possible so as to be outside the range of all disturbances.

In order to simplify a proposed elastic-shaft geared drive, with the object of securing an arrangement which shall have the least number of possible critical speeds, and therefore the least chance of coincidence of any of these with any impressed periodic actions arising either from the action of unknown internal irregularity or known and unknown external periodic disturbances, a certain amount of ingenuity is required. No common line of procedure can be chosen which will be suitable for the most general arrangement. When designing a drive one may have to study the peculiarities of the known disturbing elements, and in some cases it may be necessary to split these elements into their component parts. In all such cases the component parts will consist of a fundamental and a series of harmonics having periodicities that are simple multiples of the periodicities of the main feature of the disturbance. Such considerations will lead to the formation of a family of periodicities. An arrangement of the drive will then have to be made of such a nature that the possible critical speeds are so placed that synchronism does not occur between any one of them and any member of the family of the impressed periodicities. General considerations on a question such as this are of course always difficult to deal with, but after carefully considering the possible variations of the numerous elements with which we are concerned in elastic-shaft geared drives, the author is led to the opinion that the required reductions are best secured by: (1) Simplifying the system; (2) tuning the system; (3) making the elasticities and masses of certain shafts dynamically similar; (4) adjusting the phases of the disturbance; (5) attempting the elimination of high periodicity disturbances by lowering the pitch of the possible free vibrations of the system; (6) arranging the periodicities of the disturbance in a definite and simple family; and (7) reducing the moments of inertia of the wheels of the attendant train to the least possible value.

The difference in behavior of single-reduction and double-reduction systems would appear to be partly explained as arising from the simple nature of the former. In a single-reduction arrangement there are only one-half the number of tooth connections, and hence, roughly speaking, only one-half the number of possible critical speeds and smaller critical-speed ranges than in the corresponding double-reduction arrangement. With the present haphazard method of designing them, the single-reduction arrangement has a far better chance of success than the corresponding double-reduction type. It should not be necessary to dwell on this aspect of the question; the mathematics given in the paper should make it quite clear, for example, that any arrangement having two or more masses attached at different points to any shaft must either be cut out, or precautions must be taken to bind the masses together so that they behave practically as one solid mass. The suggested use of a flywheel on the propeller shaft is without doubt a mistake; it would increase the degrees of freedom of the system and hence the number of possible critical speeds. Any change in the moments of inertia of the propeller or of the shaft dimensions would not increase the number of possible critical speeds, and is therefore not objectionable. It may be observed also that all elastic shafts in the gear box must be cut out; that is, the driver and drive wheels mounted on any shaft must be bound as rigidly together as possible. In short, our systems must be reduced to a one-mass shaft system, and if this is done we have simplified the system in a general way as far as it is possible.

It is often possible to make a group of shafts, together with their attached masses and transmitted torques, dynamically similar, and in such cases the behavior of all the shafts in the group becomes identical and they can be treated as one individual shaft. In this way the number of tooth connections is reduced from the number appearing in the group of shafts to the number appearing in one shaft, and hence the critical ranges will be the same for all members of the group. The simplest conditions to be satisfied in such a reduction are first that the shafts of the group are tuned to the same free periodicity; second, that the masses mounted on the shafts are identical; and third, that the torques transmitted by the shafts are the same. The simplification dealt with here will be of importance when the external disturbing periodic couples can be reduced to one couple action on one shaft.

In certain cases the phase of the disturbing periodic couples will be known with a fair degree of accuracy, and hence by an adjustment of various shafts it will be possible to arrange that these couples cancel each other when taken in pairs. In such arrangements the shafts considered will have to be tuned to the same periodicity and assembled in an appropriate manner. As an example of this, it might be stated that the simplest nodal arrangement which could be devised, if the elimination of the fluctuating torque arising from propeller-blade disturbance is the important consideration, would consist of twin propeller shafts connected to one gear box and suitably assembled.

The author suspects that in many cases angular oscillations have been occurring in turbine rotors, and have been so pronounced as to give rise to appreciable fluctuating couples. If such periodic torques are possible it would appear that they can only be tuning down the possible free vibrations of the system in question to the lowest pitch.

As a general conclusion on simplification the author states that the tuning or nodalizing of any gear drive is the most direct and important dynamical means of attacking the problem when it is proposed to reduce the number and magnitude of the possible critical-speed ranges.

In order to illustrate the use of the equations and conclusions deduced analytically, the author deals in a broad way with two simple problems in which the arrangement of gears and elastic shafts consists of two prime-mover shafts geared to one propeller shaft, which is the common form of arrangement used in ship propulsion. He also gives what he calls a critical-speed diagram. This part, though interesting, cannot be abstracted owing to the lack of space. (Paper before The Institution of Naval Architects (British), read April 6, 1922, and abstracted through *Engineering*, vol. 113, nos. 2936 and 2937, Apr. 7 and 14, 1922, pp. 438–440 and 467–469, 1 fig., *tmA*)

PUMPS

Pipe Friction and Pump Efficiency. Discussion of a paper by W. Brazenall read previously before the Mining Institute of Scotland. The speakers point out the great losses of money in collieries through the use of inefficient pumping installations. The *Iron and Coal Trades Review*, vol. 104, no. 2826, Apr. 28, 1922, p. 611, *p*)

New Vacuum Pump, H. Vigneron. While the new pump is built on the same basic principle as the Gaede vacuum pump, using an eccentric rotation of a heavy cylinder in a hollow cylindrical chamber, it is capable of producing a vacuum equal to 0.0001 mm. of mercury and of doing this in one unit, i.e., without the intervention of an auxiliary pump.

The original article describes and illustrates the details of this pump. In tests made in exhausting a container having a volume of 13 liters (3.43 gal.) the pump running at 225 r.p.m. produced the following vacuums: at the end of 30 min. a pressure of 0.00786 mm. of mercury; at the end of one hour 0.00119 mm., and at the end of two hours 0.00092 mm. of mercury. (*La Nature*, no. 2504, Apr. 1, 1922, pp. 197–199, 3 figs., *d*)

RAILROAD ENGINEERING

Superheater Flue-Hole Liners. The author advocates copper liners in the firebox tubeplates of superheater boilers as a means of combating the difficulties arising from deterioration of tube holes and the constant leakage produced thereby. He describes in some details the manufacture of liners and their fitting into the tubeplate as well as the tools used.

As an example of the value of these liners is cited the case of a heavy passenger engine used on the main line between London and Carlisle with superheater tube holes of the firebox tubeplate $4^{3}/_{8}$ in. in diameter. There was, however, constant trouble with leaky tubes, necessitating frequent rolling and rerolling which resulted in rapid deterioration of the plate, so that in February, 1915, after one year

and ten months' service, it became necessary to fit a new firebox tubeplate. This new plate lasted for a year and eight months and the engine had to be returned to the shops for repairs in December, 1916. By this date smoke-tube-hole liners had been introduced and eleven of them were fitted in the tubeplate of the boiler. After a run of approximately 71,000 miles the engine was again in for repairs in December, 1917, that is, after two years and eight months' time, and the condition of the tubeplate was such that it was decided to take these eleven liners out and equip the plate with a full set of twenty-four. The new plate remained in service until September, 1919; that is, the liner-equipped plate had a life $2^1/_2$ times that of the former plate not so equipped. These liners have also done good service in engines fitted with steel fireboxes and have been successfully applied to the repair of cracked tubeplates. (*The Railway Engineer*, vol. 43, no. 507, April, 1922, pp. 134–135, 12 figs., *d*)

Locomotive Types from a Transportation Viewpoint, J. F. Porterfield. The items going to make up the cost of freight-train operation, except crew wages, do not materially decrease with the increase of locomotive capacity. From various estimates the increased cost of maintaining the large 2-10-2 type compared with the cost of the 2-8-2 or Mikado type, works out at about 20 per cent with a decrease of about 10 per cent in mileage, these items with the increased cost of ownership being about equal to the saving in crew wages.

There is a useful field for the large locomotive where grades exceed 0.5 per cent, and particularly where the preponderance of traffic is in the heavier commodities not requiring preferential movement. On train districts with easier grades where the traffic is fairly well divided between the heavier and lighter commodities the Mikado-type locomotive is the proper type to use. The Mikado type is also better adopted to movement of high-class freight. All of these statements are supported by the author by various calculations.

On the whole, he comes to the conclusion that because of the increased cost of maintenance and of ownership and the decrease in efficiency of the extremely large types of locomotives, careful study and consideration should be given to the grade and traffic conditions, the train frequency or road capacity, the terminal expense required to reduce or increase trains, and other operating conditions before making an investment in locomotives of the larger types. Consideration should also be given to increasing the hauling capacity and productive time or mileage of the existing types, as well as reducing the fuel cost of their operation. (Paper before the Western Railway Club, Apr. 17, 1922, abstracted through *Railway Review*, vol. 70, no. 16, Apr. 22, 1922, pp. 565–566, 1 fig., *pc*)

Flexible-Pipe Feedwater Connections Between Engine and Tender. The connections were made on consolidation-type locomotives on the Bangor and Aroostook. At first there was a single large pipe line on the center line of the locomotive through which both injectors were fed, but this type of connection met with the objection that a failure of the pipe would entirely cut off the feedwater supply and cause a complete engine failure. Because of this the arrangement was changed so as to provide a separate connection for each injector.

At the tender end the connections are attached to plates riveted to the bottom of the tank, and the upper joints are each connected by a short nipple to one of the tank wells. This arrangement with the connections apply directly to the tank instead of to the tender frame is intended to eliminate the possibility of leakage, resulting from slight shifting of the tank.

Connections of this type with feed lines 2 in. in diameter have been in service for several months during the past winter, during which time the locomotives have averaged about 30,000 miles with no maintenance required to the feedwater line. The severe climatic conditions prevailing during the winter months on this line require almost constant use of the heaters when the injectors are not working, and it is estimated that the same service would have required at least one and probably two renewals of the ordinary hose connections. (*Railway Age*, vol. 72, no. 18, May 6, 1922, p. 1070, 1 fig., *d*)

Springs and Draft-Gear Design Data for Freight Cars

Springs, Draft Gears and Other Problems in Car Design, Prof. Louis E. Endsley. In the design of a freight car there are two distinct problems to be taken into consideration. One is the direct vertical load, and the other is the shock or pressure produced between two cars whenever they come together at varying speeds.

None of the parts above the springs should receive shocks from a direct vertical load, and by shocks is meant here that force which is produced by the springs going solid.

The author believes that springs should be designed with a greater capacity than is now done is some instances, and the capacity of springs should not be less than 200 per cent of the normal weight of the car and lading, with the car standing still, and 250 per cent would probably be even better.

In tests made by the author on the Pennsylvania Railroad in 1914, he found that with 200 per cent spring capacity in trips of the experimental car between Pittsburgh and Alliance many solid impact blows were delivered between the bolster and the side frame. Another set of springs which were 300 per cent of the normal load never went solid and there was only one impact recorded that was over 225 per cent of the normal load.

The use of springs of greater capacity would not only protect the car better but would also reduce materially the breakage of springs. The parts of the car which are below the springs, namely, the side frames, need extra weight in them. In tests which the author made to determine the effect of the impact blow upon the side frame after the springs went solid, he found that it takes only a little more energy than that necessary to close the springs to cause some very excessive forces.

Draft-gear problems with modern solid steel cars are not considered to have been entirely solved. They would have been, however, if a draft gear had been used in each car that would never go solid without a pressure above the coupler and still strength but this is not a fact, as we have never yet been able to keep our switching speeds below the impact point.

The old wooden underframe for freight cars was in a better condition to withstand stresses than the modern steel underframe, because it gave two inches as compared with the give of one inch for the steel frame. On the other hand, however, railroads are now willing to permit an increase in draft-gear travel.

Steps should be taken to keep the draft-gear capacity up so that we can keep in the service longer the old and medium-weight cars. If our old cars have an impact capacity of only 600,000 or 700,000 lb., and we design cars with a new underframe that has a capacity of over 1,000,000 lb. and these cars come in contact, without an adequate draft gear in each of them, there is not much doubt which one of the cars is going out of commission. As long as we keep together two cars of equal strength they will stand a great many impact blows in the switching after the draft gear goes solid, but when they come into contact with cars of greater capacity the old cars will go out of commission very fast; while if we should design the new cars with a draft gear and arrangement that would take care of a reasonable switching speed, we would keep in service many cars which are now going out of service. Today we have draft gears which will take care of switching speeds between $3^1/_2$ and 5 miles an hour when new, but unless they are kept under repairs, the speed at which they will protect the car will be reduced considerably. (Abstract of an address before the recent meeting of the Virginia Section of The American Society of Mechanical Engineers. *Railway Review*, vol. 70, no. 17, Apr. 29, 1922, pp. 591–594.)

ROLLING MILLS

Power Required to Roll Wrought-Iron Bars, Edwin L. Fletcher. Results of tests in reducing 3-in. billets to $^1/_2$-in. round, of particular interest because of the comparative scarcity of published information on rolling wrought iron, where the conditions are somewhat different from those obtaining in the rolling of steel.

The heat loss between the roughing mill and the merchant mill is much more serious in rolling wrought iron than in rolling steel,

and proper timing at this point may easily cut the scrap loss in half.

Under modern conditions the spacing between roughing and merchant mills may be as high as 32 ft. centers and the billets weigh from 100 to 135 lb. The original article gives data as to power consumed over a number of days of rolling of the product of eight puddling furnaces for wrought-iron bars to meet the requirements of railroad shops and chain makers. (*The Iron Age*, vol. 109, no. 17, Apr. 27, 1922, p. 1144, *e*)

SHIPBUILDING (See Power Transmission)

SPECIAL PROCESSES

Anderson Process for the Hot Rolling of Gears

The Hot Rolling of Gears, Reginald Trautschold. Description of a process devised more than ten years ago by H. N. Anderson, Mem. Am.Soc.M.E., and now practiced by the Anderson Rolled Gear Company.

In previous attempts at hot rolling of gears only one of the operating shafts of the rolling apparatus was positively driven, which produced a slip between the die roll and the blank, with the resulting distortion of the teeth of the molded gear and lack of accuracy in tooth spacing.

Mr. Anderson conceived the idea of positively driving both shafts and accurately synchronizing their rotation by means of suitable timing gears, and it was found that the gears were such that no finishing of the teeth was necessary. He was awarded for this development the John Scott Legacy Medal by the Franklin Institute in 1915.

In the actual process of rolling gears the blank heated to a temperature of from 2000 to 2100 deg. fahr. is mounted on the work arbor of the rolling machine and securely clamped in place by means of a powerful auto-manipulator. The arbors carrying the die roll and the heated blank are actuated by suitable heavy timing gears and the die and blank are rolled together in synchronized contact under a rolling pressure of from 10 to 20 tons. At the start of the rolling the die is clear of the blank, but advances gradually until the teeth of the die have penetrated the blank their full depth. As the rolling is done as a rule at speeds varying from 400 to 700 r.p.m., the advance of the die roll per revolution is very slight. This insures a thorough kneading and working down of the metal of the blank and permits easy flow of the metal as it is displaced and built up by the die.

During the rolling operation the die is cooled by a stream of water directed against its face at a point opposite to that in contact with the blank. As the entire rolling consumes less than 15 sec., this cooling prevents the temperature of the die from rising above that easily bearable by the hand. The chilling effect of the cold, wet die roll on the hot blank causes a rapid contraction of the latter and loosening of the forging scale as it is formed. The loosened scale is then thrown free by the centrifugal force due to the high speed of rotation of the blank. Because of this in the finished gear the teeth are not only perfect in shape but are highly polished on all contact surfaces.

In order to attain the highest degree of precision in the form of the teeth molded, machines designed for the production of the most accurate gears are equipped with additional mechanism for frequently and automatically reversing the rotation of the die and blank. This frequent reversing or oscillation, at somewhat reduced speeds, varying from 80 to 200 r.p.m., is maintained during the forming of the molded teeth and until the die is within 0.01 in. of full penetration. The action then automatically reverts to high-speed direct rolling for the planishing effect. The oscillating methods tend to effect displacement and building up to a somewhat more equal and constant degree on both sides of the teeth than if rolling in one direction is maintained, thereby producing a more perfectly symmetrical tooth form.

Herringbone gears may be produced as accurately and cheaply as the other types by using a compound die roll. For the production of all types of bevel gearing the crown-gear form of tooth is used and in many cases the crown-gear type of die roll. If, however, the gear to be rolled is to be of a given number of teeth of a certain pitch, such as the standard pitches now in general use, its diameter is also definitely fixed. As the diameter of a crown-type die roll is established by the length of the conical element of the gear to be rolled, it is apparent that the circumference of the crown-gear die roll may not be commensurably proportional to that of the blank. The crown-gear die roll would not, therefore, accommodate a full number of teeth of the given pitch, but this may be overcome by the use of a flat bevel die roll, shortening the diameter of the die until it is commensurably proportional to that of the gear blank.

All die-roll faces are somewhat narrower than those of the gear blanks, thus producing gears partly or wholly shrouded. Consequently, if it is desired to strengthen the weaker member of a pair of gears, the shroud may be left on, either entirely or partly, or the shrouds on the two gears may be so proportioned as to equalize the strength of the two and greatly increase that of the combination. The increase in strength cannot well be definitely established, but considering also the greater inherent strength of rolled teeth, it is probably a conservative assumption that shrouded gears can be proportioned and rolled which possess double the strength of ordinary cut gears of the same pitch.

The greater inherent strength of rolled gears is due to the effect on the structure of the metal of rolling at high temperature and under high pressure. This pressure and the thorough kneading action of the die teeth while the metal is in a plastic state, in addition to building up and compressing the metal into the formed teeth, gradually breaks up the normal coarser crystalline structure and produces a dense, thoroughly worked metal of almost fibrous characteristics. The minute crystals are rearranged in a truss formation following the periphery of the finished gear, thus tying the teeth to the body of the gear and equalizing the structural strains. In fact, the reduction of internal structural strains is so marked that no distortion whatever occurs in subsequent heat treatment of the gears and it has even been found unnecessary to use any clamps for the purpose of holding the gear true when quenching.

The modified metal structure also materially increases the hareness and wearing qualities of the gear teeth and assures a mord uniform result from case-hardening or other heat treatment. Exacting laboratory tests, confirmed by service tests under the most severe operating conditions, have shown an average superiority for rolled gears of 25 per cent in strength and 20 per cent in hardness, as shown in the tables.

	Machine-cut gears	Hot-rolled gears
Normal Condition:		
Yield point	6470 lb.	7918 lb.
Ultimate strength	12250 lb.	13645 lb.
Hardness	22	26
Case-Hardened:		
Yield point	13529 lb.	14750 lb.
Ultimate strength	17250 lb.	19130 lb.
Hardness	87	85
Depth of case	0.027 in.	0.035 in.

It is stated that the gear-rolling method is more economical than the usual machining process.

The problem of ultimate perfection of the process thus became primarily one of developing a system of die rolls which would form perfect and efficient gears with a high degree of accuracy at low cost and which could be redressed when necessary without affecting the precision of form of the molded teeth. The perfection of such a system of dies and their adaptation to use on a practical and efficient machine operating on the principle evolved have now made feasible the commercial production of gears by a true molding process. CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society.

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A.S.M.E.

Research Résumé of the Month

A—RESEARCH RESULTS

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a resume of research results with formulas or curves where such may be readily given, and to report results of non-extensive researches which in the opinion of the investigators do not warrant a paper.

Coal. THE IGNITION TEMPERATURE OF COAL. See *Fuels, Gas, Tar and Coke A9-22.*

Electrolysis A1-22. ELECTRODEPOSITION OF IRON. In view of the extended use of electrodeposition of iron for many industrial purposes the Department of Scientific and Industrial Research, Westminster, London, S. W. 1, has considered it advisable to issue the present bulletin which embodies the results of research carried out by W. E. Hughes, with the assistance of grants made by the Department.

The contents of the report are arranged under the following headings:

Division 1: Descriptive. (*a*) General note on the description of the deposits; (*b*) Series I, on the effect of temperature; (*c*) Series II, on the effect of current density; (*d*) Series III, on the effect of mechanical movement.

Division 2: Theoretical. (*a*) The crystallization of substances in general; (*b*) application to electrodeposited metal; a consideration of the results of the experiments of the Series I, II, and III. Some remarks on deposits (1) from other iron solutions; (2) of other metals. General conclusions; (*c*) workshop application.

Appendix. Bibliography comprising references to publications on: (*a*) the electrodeposition of iron and phenomena connected therewith; (*b*), the properties of electroltyic iron; (*c*), works of reference relating to the electrodeposition of iron.

The bibliography will be of use to those desiring general information upon the subject, as well as to research workers. The report is copiously illustrated by microphotographs. Copies of the report may be obtained by addressing His Majesty's Stationery Office for the Department of Scientific and Industrial Research, Imperial House, Kingsway, London, W. C. 2. Price per copy 6s. 6d. (By mail, 6s. 8½ d.)

Expansion A1-22. THERMAL EXPANSION OF A FEW STEELS. Scientific Paper No. 433 of the Bureau of Standards on this subject was prepared by Wilmer Souder and Peter Hidnert. Thermal-expansion data on 28 samples of iron and steel are given. One sample of vacuum electrolytic iron and one of gray cast iron are included. A specimen of hardened steel has been tested to show the dimensional changes incident to heat treatment or drawing. Twenty-two curves and a 2-page table are used to summarize the results.

The average expansion of the specimen of electrolytic iron is 12.0×10^{-6} for the range 25 to 100 deg. cent.

For 25 steels:

11.2×10^{-6} for the range 25 to 100 deg. cent.

14.2×10^{-6} for the range 25 to 600 deg. cent.

Above the critical region the values usually jump to approximately 23×10^{-6}.

The values on cooling are not very different from those on heating; the transformation regions are displaced as usual.

The contraction and expansion reversals within the critical regions vary from a few microns per meter, if any at all, for a 3.7 per cent silicon steel, to almost 2000 microns per meter for a 1.2 per cent chrome steel (C. 0.35; Cr., 1.17; V. 0.14).

The critical region was found to extend over a temperature interval of from less than 6 deg. cent. for electrolytic iron to something over 100 deg. cent. for a special 1.1 per cent manganese steel. These differences in dimensional changes and extent of critical region are suggested as a means for determining the tendency toward cracking or warping when parts of specimens are quenched at unequal rates. This rate is always different, depending upon the size, shape, etc. The specimen of cast iron showed irregularities and considerable permanent growth upon heating, the growth being especially rapid at temperatures above 650 deg. cent.

A brief review of some of the previous work on expansion is included. Copies may be obtained by addressing the Superintendent of Documents, Government Printing Office, Washington, D. C. Price 5 cents per copy.

Forest Products A1-22. TECHNICAL NOTES. For the past three years and more the Forest Products Laboratory of the U. S. Forest Service has issued technical data sheets (8×10½ in.) which cover a variety of subjects of special interest to the manufacturer, dealer and user of lumber, wood and wood products.

Many of these Technical Notes are of interest to mechanical engineers. A few of the subjects are therefore listed below by way of illustration. A-3, How to Make Factory Roof Timbers Last Longer; B-3, Metal Strapping on Wooden Boxes; B-9, Preparation of Stock for Bending; B-10, The Nailing of Boxes; 92, When to Heat Wood Before Gluing; 98, Fuel Value of Wood; 101, Comparative Value of Timber Cut from Live and Dead Trees; 105, What Is Dry Rot? 106, Making Wood Fire-Resistant with Paint; 110, Saving Mine Timbers from Decay; 130, Tie Renewals in Relation to Average Life; 134, The Crate Corner; 149, Strength of Screw Fastenings in Plywood; 121, Automatic Control of Humidity in Shops; and 122, Comparison of Five Different Types of Glue.

Fuels, Gas, Tar and Coke A9-22. THE IGNITION TEMPERATURE OF COAL. Bulletin No. 128 of the University of Illinois Engineering Experiment Station, just issued, is a careful study of this subject by Ray W. Arms.

In his introduction he states that there is no definite temperature at which coal bursts into flame. The phenomenon of flame from coal is due to the combustion of volatile matter driven off from the coal, the character of such matter varying under different conditions; hence the temperature at which the coal flames varies widely and is dependent upon surrounding conditions, and therefore the flaming temperature of a coal does not serve as an indication of the ignition point. Strictly speaking, it is the true ignition point, but since it varies so widely its evaluation is meaningless.

The first purpose of this investigation, therefore, was to establish some definite point along the line of this process of heating which could be called the ignition temperature. In the effort to locate such a temperature heating curves were drawn to show the rate at which the coal increased in temperature when assisted by an outside source of heat. After a study of these curves the point at which the coal assumed a uniform glow was chosen as the most logical ignition temperature, not only because this point was found to be rather definite in the heating curve, but also because it could be checked in various types of apparatus by different means of temperature measurement and control, and by different operators.

Mr. Arms' five conclusions are:

1 The "ignition temperature" of coal means nothing unless it is applied to some definite point in the process of heating the coal, which can easily be determined and duplicated.

2 The temperature at which the coal glows seems to be the most logical point to choose as the ignition temperature. It is easily observed, can be duplicated with a fair degree of accuracy, and marks the beginning of visible combustion.

3 The glow point is probably affected by the oxygen content of the coal, and perhaps by other agencies made active by weathering.

4 The glow point is not affected by ash, moisture, size of particles, slight variations from the normal air supply, or rate of heating.

5 There is no indication at present that the glow point bears any direct relation to the liability to fire while in storage. Perhaps if a series of tests were made on the glow points of freshly mined coal new information would be brought to light which would lead to the discovery of some more definite relation between glow point and the firing qualities of the coal.

Internal-Combustion Engines A1-22. THE BACKGROUND OF DETONATION. This is the subject of Technical Note No. 93 recently prepared by the National Advisory Committee for Aeronautics. It has for its object the discussion of a phase of this question which so far has received but little attention. The effect of the temperature and pressure of the charge before combustion is especially considered, as it is believed that a careful study of this "background" can throw considerable light on results that have been obtained in investigations of detonation both at the Bureau and elsewhere.

The circumstances under which detonation occurs are described, and the effects of varying conditions in the engine are discussed. The work of Harry R. Ricardo in England receives a great deal of attention, and it is believed that additional facts have been deduced from the data which he obtained.

It is shown that compression and explosion pressures, scavenging, and the operation of the ignition system all play a prominent part in the phenomenon of detonation. The influence of changes in fuel characteristics is believed to lie outside the province of this paper and is not taken up in any detail.

Preignition and detonation are conceded to be entirely independent phenomena, and it is shown that overheating troubles are more likely to be from preignition than from detonation. Curves and diagrams illustrating various phases of the subject are presented, and the whole forms a valuable contribution to the study of the internal-combustion engine. Those desiring copies should write directly to the above-named committee at 2722 Navy Building, Washington, D. C.

Iron and Steel A2-22. THERMAL EXPANSION OF A FEW STEELS. See *Expansion A1-22.*

B—Research in Progress

The purpose of this section of Engineering Research is to bring together those who are working on the same problem for cooperation or conference, to prevent unnecessary duplication of work and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

Automotive Vehicles and Equipment B2-22. Power Loss in Automobile Tires. The rubber laboratory of the Bureau of Standards is equipped with a special dynamometer for determining, among other things, the power loss in automobile tires. A great many of the standard makes of tires have been tested on this dynamometer, and valuable data are being obtained concerning the percentage of the power of an automobile engine which is absorbed by the tires under various conditions.

Some interesting figures have already been secured as a result of this work. For instance, an average 4-in. fabric tire, under conditions of normal load and air pressure, will absorb approximately 0.90 hp. due to rolling resistance at a speed of 25 miles per hour. Under the same conditions, the power loss in a 4-in. cord tire is approximately 0.60 hp., while a 5-in. cord tire represents a loss of 1.20 hp. The extent to which different parts of the tire contribute to the power loss has also been investigated. It is estimated that from 80 to 85 per cent of this loss is in the carcass, the tread contributes 10 to 15 per cent, and the tube probably less than 5 per cent.

Boilers B1-22. Specifications for Refractories. See *Refractories B1-22.*

Corrosion B3-22. Resistance of Chromium Steels to Atmospheric Corrosion. For resisting corrosion by water and air, a considerable amount of chromium in a steel is necessary, and alloys of this general type were found much more resistant than were those of low chromium content. These latter steels, however, were found much more resistant than the simple carbon steel or "pure" iron. Hardening the chromium steel by heat treatment retarded corrosion by water and air as it did in the acid tests. This was true, in particular, for the steels of high chromium content, while variations in heat treatment produced very little difference in resistance to corrosion in specimens lower in chromium. Adhering patches of oxide scale upon the surface were found to have a very noticeable effect in accelerating the rate of attack of the chromium steels.

The alloy containing a high percentage of nickel, as well as chromium, found to be attacked the least by acid, also proved much more resistant to atmospheric corrosion than most of the chromium steels tested, although it was far surpassed by certain of the high-chromium materials.

In most cases corrosion of the chromium steels consisted in an attack at small isolated spots rather than in a general tarnishing and coating of the surface. This, in view of the fact that adhering particles of scale accelerate the corrosive attack of a steel to a very marked degree, suggests that the presence of inclusions or other defects within the material may be responsible in large measure for the character of the resulting surface pattern.

The character of the service should govern the type of "non-corrodible" steel to use. For example, if resistance to severe acid attack is the principal requirement, a high-chromium steel is the least suitable of all the materials tested. However, most classes of service require fairly satisfactory performance under a variety of conditions. Thus, for example, cutlery steel must withstand *both* acid and atmospheric corrosion as well as possess certain necessary mechanical properties, "forgeability," hardness, etc. No single type of non-corrodible steel appears to be suitable for each and every purpose which may arise. Address Dr. S. W. Stratton, Director, Bureau of Standards, Department of Commerce, Washington, D. C.

Non-Ferrous Metals B1-22. Spectroscopic Analysis of Bronzes. An examination of five bronzes for impurities for the purpose of establishing the spectrographic method for quantitative estimation of small amounts of aluminum and silicon which are detrimental in bronze or brass castings has been recently undertaken by the Bureau of Standards. A progress report on this practical application of spectrum analysis was presented at the Nonferrous Metals Committee Meeting on April 24.

Refractories B1-22. Specifications for Refractories. At the last meeting of the Bureau of Standards Advisory Committee on specifications for refractories, it became evident that additional investigation would be necessary to determine what test requirements are most effective in drawing the line between satisfactory and unsatisfactory brick for furnace linings in stoker-fired boilers. As a result preparations are being made to conduct an extended series of tests, including a 72-hour reheating test at 1450 deg. cent. A prominent consulting engineer is coöperating with the Bureau in this work and in addition to gathering information as to the suitability of different brands of brick, is arranging to have a quantity of samples representing about 20 brands shipped to the Bureau of Standards by the users.

Rubber and Allied Substances B1-22. Power Loss in Automobile Tires. See *Automotive Vehicles and Equipment B2-22.*

F—Bibliographies

The purpose of this section of Engineering Research is to inform the profession of bibliographies which have been prepared. In general this work is done at the expense of the Society. Extensive bibliographies require the approval of the Research Committee. All bibliographies are loaned for a period of one month only. Additional copies are available, however, for periods of two weeks to members of the A.S.M.E. These bibliographies are on file at the office of the Society.

Forest Products F1-22. Preservation of Mine Timber. This bibliography, prepared by R. R. Hornor for the Bureau of Mines, consists of six closely typewritten pages 8×10½ in. in size. It is known as Serial No. 2343 and may be obtained by addressing H. Foster Bain, Director, Department of the Interior, Bureau of Mines, Washington, D. C.

Petroleum and Allied Substances F3-22. A List of Recent Articles. This bibliography lists under eleven headings the literature on this subject which was published during the months of March and April. The compiler is E. H. Burroughs, Bibliographer of the Bureau of Mines. It is one of the Bureau's Reports of Investigations, Serial No. 2348.

Wood Products (other than Cellulose and Paper) F1-22. Preservation of Mine Timber. See *Forest Products F1-22.*

Second Revision of A.S.M.E. Boiler Code, 1922

A HEARING is held by the Boiler Code Committee at least once in four years, at which all interested parties may be heard, in order that such revisions may be made as are found to be desirable, as the state of the art advances. The year 1922 becomes the period of the second revision, the first revised edition of the Boiler Code having been issued in 1918. The Boiler Code Committee plans to hold a Public Hearing in connection with the next Annual Meeting of the Society in December, 1922, to which the membership of the Society and everyone interested in the steam-boiler industry will be cordially invited to attend and present their views.

In the course of the Boiler Code Committee's work during the past four years, many suggestions have been received for revisions of the Power Boiler Section of the Code, as a result of the interpretations issued and also of the formulation of the Locomotive Boiler and Miniature Boiler Codes. In order that due consideration might be accorded to these recommendations, the Committee began in the early part of 1921 to devote an extra day at each of its monthly meetings to the consideration of the proposed revisions. As a result of this many of the recommendations have been accepted and revisions of the paragraphs formulated.

The revisions which have met the approval of the Boiler Code Committee are here published. It is the request of the Committee that these revisions be fully and freely discussed so that it may be possible for anyone to suggest changes before the rules are brought to final form and presented to the Council for approval. Discussions should be mailed to C. W. Obert, Secretary to the Boiler Code Committee, 29 West 39th St., New York, N. Y., in order that they may be presented to the Boiler Code Committee for consideration.

The revisions here published are limited to the paragraphs appearing in the 1918 Edition of the A.S.M.E. Boiler Code, and the paragraph numbers refer to the paragraphs of similar number in that edition. For the convenience of the reader in studying the revisions, all added matter appears in small capitals and all deleted matter in smaller type.

Par. 9 Revised:

9 Cross pipes connecting the steam and water drums of water-tube boilers, headers, cross boxes and all pressure parts of the boiler proper over 2-in. pipe size, or equivalent cross-sectional area, shall be of wrought steel, or cast steel of Class B grade, as designated in the Specifications for Steel Castings, when the maximum allowable working pressure exceeds 160 lb. per sq. in. THE USE OF BESSEMER STEEL IS PROHIBITED FOR THE PRESSURE PARTS OF BOILERS. Malleable iron may also be used when the maximum allowable

Note: Matter deleted, in smaller type; matter added, in small capitals.

working pressure does not exceed 200 lb. per sq. in., provided the form and size of the internal cross-section perpendicular to the longest dimension of the box, is such that it will fall within a 7 in. by 7 in. rectangle.

Par. 12 Revised:

12 Cast iron shall not be used for nozzles or flanges attached directly to the boiler for any pressure or temperature. CAST IRON SHALL NOT BE USED [nor] for boiler and superheater mountings such as connecting pipes, fittings, valves and their bonnets, for steam temperatures of over 450 deg. fahr.

Par. 20 Revised:

20 The minimum thicknesses of tube sheets for FIRE-TUBE [horizontal return tubular] boilers, shall be as follows:

When the diameter of tube sheet is

42 In. or under	Over 42 in. to 54 in.	Over 54 in. to 72 in.	Over 72 in.
$^3/_8$ in.	$^7/_{16}$ in.	$^1/_2$ in.	$^9/_{16}$ in.

Par. 25 Revised:

25 *Chemical Composition.* The steel shall conform to the following requirements as to chemical composition:

		Flange	Firebox
Carbon		Plates $^3/_4$ in. thick and under—NOT OVER [illegible] 0.25 per cent Plates over $^3/_4$ in. thick—NOT OVER [illegible] 0.30 per cent	
Manganese		0.30–0.60 per cent	0.30–0.50 per cent
Phosphorus	Acid.	Not over 0.05 per cent	Not over 0.04 per cent
	Basic.	Not over 0.04 per cent	Not over 0.035 per cent
Sulphur		Not over 0.05 per cent	Not over 0.04 per cent

Par. 29 Revised:

29 *Modifications in Elongation.* *a* For material over $^{11}/_{16}$ in. in thickness: From the figure representing the percentage of elongation required as determined in accordance with Par. 28 *a*, there shall be deducted an amount equal to four times the difference between the ordered thickness in inches and $\frac{3}{4}$ [$^{11}/_{16}$] in., except that the minimum elongation required shall in no case be less than 20 per cent.

b For material $^1/_4$ in. in thickness, the elongation shall be measured on a gage length of 6 in.

Par. 36 Revised:

36 *Marking.* *a* Each shell plate shall be legibly stamped by the manufacturer with the melt or slab number, name of manufacturer, grade and the minimum tensile strength of the stipulated range as specified in Par. 28, in TWO [three] places, [two of] which shall be located NOT LESS THAN [at diagonal corners about] 12 in. from the edge [and one about the center] of the plate, or at TWO [a] points selected and designated by the purchaser so that AT LEAST ONE [the] stamp shall be plainly visible when the boiler is completed.

b Each head shall be legibly stamped by the manufacturer in two places, about 12 in. from the edge, with the melt or slab number, name of manufacturer, grade, and the minimum tensile strength of the stipulated range as specified in Par. 28, in such manner that the stamp is plainly visible when the boiler is completed.

c Each butt strap shall be legibly stamped by the manufacturer in two places on the center line about 12 in. from the ends with the melt or slab number, name of manufacturer, grade, and the minimum tensile strength of the stipulated range as specified in Par. 28.

d The melt or slab number shall be legibly stamped on each test specimen.

Add the Following to Par. 36:

e IT IS PERMISSIBLE TO TRANSFER, WITHOUT IMITATION, THE MARKINGS ON THE PLATE UNDER AUTHORITY OF AN AUTHORIZED INSPECTOR IN CHARGE; SAID INSPECTOR TO PUT HIS PRIVATE MARK AFTER THE TRANSFERRED STAMP.

f IF, DURING FABRICATION IN THE BOILER SHOP, REMOVAL OF BOTH GROUPS OF THE PLATE MANUFACTURER'S STAMPS CANNOT BE AVOIDED BECAUSE OF THE CUTTING OR PUNCHING OF NECESSARY HOLES IN THE PLATES, ONE GROUP OF SUCH STAMPS MAY BE TRANSFERRED TO A PERMANENT POSITION BY RESTAMPING UNDER THE SUPERVISION OF AN AUTHORIZED STATE, MUNICIPAL OR INSURANCE COMPANY INSPECTOR. WHEN STAMPS ARE TRANSFERRED THE PLATE MANUFACTURER'S NAME SHALL NOT BE IMITATED. THE INSPECTOR SHALL PUT HIS PRIVATE STAMP BESIDE THE TRANSFERRED GROUP AND A RECORD OF THE TRANSFER AND THE INSPECTOR'S STAMP SHALL BE NOTED ON THE DATA SHEET. A GROUP OF STAMPS CONSISTS OF THE MANUFACTURER'S NAME, MANUFACTURER'S TEST IDENTIFICATION NUMBER, GRADE AND TENSILE STRENGTH.

Par. 48 Revised:

IV PERMISSIBLE VARIATIONS IN GAGE

48 The gage of each bar shall not vary more than 0.01 in. from that specified.

Par. 180 Add following paragraph:

THE FACTOR OF SAFETY USED IN DETERMINING THE MAXIMUM ALLOWABLE WORKING PRESSURE CALCULATED ON THE CONDITIONS ACTUALLY OBTAINED IN SERVICE SHALL NOT BE LESS THAN 5.

Par. 182 Revised:

182 The distance between the center lines of any two adjacent rows of rivets, or the "back pitch" measured at right angles to the direction of the joint, shall have the following minimum values:

a If $\frac{P}{[\mathrm{D}]\mathrm{d}}$ is 4 or less, the minimum value shall be $2[\mathrm{D}]\mathrm{d}$;

b If $\frac{P}{[\mathrm{D}]\mathrm{d}}$ is over 4, the minimum value shall be:

$$2[\mathrm{D}]\mathrm{d} + 0.1\,(P - 4[\mathrm{D}]\mathrm{d})$$

where

P = pitch of rivets in outer row where a rivet in the inner row comes midway between two rivets in the outer row, in.

P = pitch of rivets in the outer row less pitch of rivets in the inner row where two rivets in the inner row come between two rivets in the outer row, in. (It is here assumed that the joints are of the usual construction where the rivets are symmetrically spaced.)

$[\mathrm{D}]\mathrm{d}$ = diameter of the rivet holes in.

Par. 194 Revised:

194 *Domes.* THE REQUIREMENTS OF PARS. 187 AND 188 SHALL APPLY TO RIVETED LONGITUDINAL JOINTS OF DOMES EXCEPT THAT FOR DOMES 24 IN. AND LESS IN DIAMETER FOR PRESSURES EXCEEDING 100 LB., THE LONGITUDINAL JOINTS MAY BE LAP-RIVETED IF THE FACTOR OF SAFETY IS NOT LESS THAN 8. [The longitudinal joint of a dome 24 in. or over in diameter shall be of butt and double-strap construction, irrespective of pressure. When the maximum allowable working pressure exceeds 100 lb. per sq. in., the flange of a dome 24 in. or over in diameter shall be double-riveted to the boiler shell.]

THE FLANGE OF A DOME 24 IN. OR OVER IN DIAMETER SHALL BE DOUBLE-RIVETED TO THE BOILER SHELL. WHERE THE FLANGE OF THE DOME IS USED FOR REINFORCING OR ATTACHING IT TO THE SHELL, THE DIAMETER OF THE DOME SHALL NOT EXCEED ONE-HALF THE DIAMETER OF THE SHELL OR BARREL OF THE BOILER. [The longitudinal joint of a dome less than 24 in. in diameter may be of the lap type, and its flange may be single-riveted to the boiler shell provided the maximum allowable working pressure on such a dome is computed with a factor of safety of not less than 8.]

The dome may be located on the barrel or over the fire-box on traction, portable or stationary boilers of the locomotive type up to and including 48 in. barrel diameter. For larger barrel diameters, the dome shall be placed on the barrel.

Flanges of domes shall be formed with a corner radius, measured on the inside, of at least twice the thickness of the plate for plates 1 in. thick or less, and at least three times the thickness of the plate for plates over 1 in. in thickness.

Par. 201 Revised:

201 *Structural Reinforcements.* When channel irons or other members are securely riveted to the boiler heads for attaching through stays, the transverse stress on such members shall not exceed 12,500 lb. per sq. in. In computing the stress, the section modulus of the member shall be used without addition for the strength of the plate. The spacing of the rivets over the supported surface shall be DETERMINED BY THE FORMULA IN PAR. 199 USING 135 FOR THE VALUE OF C [in conformity with that specified for staybolts.]

If the outstanding legs of the two members are fastened together so that they act as one member in resisting the bending action produced by the load on the rivets attaching the members to the head of the boiler, and provided that the spacing of these rivets attaching

the members to the head is approximately uniform, the members may be computed as a single beam uniformly loaded and supported at the points where the through braces are attached.

PAR. 205 REVISED

205 The distance from the edge of a staybolt hole to a straight line tangent to the edges of the rivet holes may be substituted for p for staybolts adjacent to the riveted edges bounding a stayed surface. When the edge of a FLAT stayed plate is flanged AND RIVETED, THE DISTANCE FROM THE CENTER OF THE OUTERMOST STAYS TO THE INSIDE OF THE SUPPORTING FLANGE SHALL NOT EXCEED THE PITCH OF THE STAYS, p, PLUS THE INSIDE RADIUS OF THE FLANGE [p shall be measured from the inner surface of the flange, at about the line of rivets to the edge of the staybolts or to the projected edge of the staybolts.]

PAR. 206 REVISED:

206 The MAXIMUM PITCH p AS GIVEN IN PAR. 199 [distance between the edges of the staybolt holes] may be INCREASED BY THE STAYBOLT HOLE DIAMETER WHERE [substituted for p for] staybolts ARE adjacent to a furnace door or other boiler fitting, tube hole, handhole or other opening.

PAR. 212*c* REVISED:

c A FURNACE FOR A VERTICAL FIRE-TUBE BOILER, 38 IN. OR LESS IN OUTSIDE DIAMETER, WHICH REQUIRES STAYING, SHALL HAVE THE FURNACE SHEET SUPPORTED BY ONE ROW OF STAYBOLTS, OR MORE, THE CIRCUMFERENTIAL PITCH NOT TO EXCEED 1.05 TIMES THAT GIVEN BY THE FORMULA IN PAR. 199 AND IN TABLE 4.

THE LONGITUDINAL PITCH BETWEEN THE STAYBOLTS, OR BETWEEN THE NEAREST ROW OF STAYBOLTS AND THE ROW OF RIVETS AT THE JOINTS BETWEEN THE FURNACE SHEET AND THE TUBE SHEET OR THE FURNACE SHEET AND MUD RING, SHALL NOT EXCEED THAT GIVEN BY THE FOLLOWING FORMULA:

$$\mathrm{L} = \frac{(220 \times \mathrm{T}^2)^2}{(\mathrm{P} \times \mathrm{R})}$$

EXCEPT WHEN THIS VALUE IS LESS THAN THE CIRCUMFERENTIAL PITCH, IN WHICH CASE THE LONGITUDINAL PITCH MAY BE AS GREAT AS THE ALLOWABLE CIRCUMFERENTIAL PITCH

where

L = LONGITUDINAL PITCH OF STAYBOLTS
T = THICKNESS OF FURNACE SHEET IN SIXTEENTHS OF AN INCH
P = MAXIMUM ALLOWABLE WORKING PRESSURE IN LB. PER SQ. IN.
R = OUTSIDE RADIUS OF FURNACE, IN INCHES.

THE STRESS PER SQUARE INCH IN THE STAYBOLTS SHALL NOT EXCEED 7500 LB. AND SHALL BE DETERMINED IN THE WAY SPECIFIED IN PAR. 212*d*.

PAR. 212*d* INSERT NEW SECTION AS FOLLOWS:

d FOR FURNACES OVER 38 IN. IN OUTSIDE DIAMETER OF VERTICAL FIRE-TUBE BOILERS AND OTHER TYPES OF FURNACES AND COMBUSTION CHAMBERS NOT COVERED BY SPECIAL RULES IN THIS CODE, WHICH HAVE CURVED SHEETS SUBJECT TO EXTERNAL PRESSURE, THAT IS, PRESSURE ON THE CONVEX SIDE, THE STAYING, BOTH CIRCUMFERENTIAL AND LONGITUDINAL, SHALL BE PROVIDED FOR IN ACCORDANCE WITH THE FOLLOWING FORMULA:

$$\mathrm{P} = \frac{\mathrm{CT}^2}{p^2} + 250\,\frac{\mathrm{T}}{\mathrm{R}}$$

WHERE p AND THE VALUE OF C ARE AS GIVEN IN PAR. 199, p SHALL NOT EXCEED 2T, AND p^2 SHALL NOT EXCEED 0 008CTR.

THE STRESS PER SQ. IN. IN STAYBOLTS SHALL NOT EXCEED 7500 LB., BASED ON A TOTAL STRESS OBTAINED BY MULTIPLYING THE PRODUCT OF THE CIRCUMFERENTIAL AND LONGITUDINAL PITCHES BY $\left(\mathrm{P} - 250\,\frac{\mathrm{T}}{\mathrm{R}}\right)$.

PAR. 217 REVISED:

217 The net area to be stayed in a segment of a head may be determined by the following formula:

$$\frac{4(\mathrm{H} - d - 2)^2}{3}\sqrt{\frac{2\,(\mathrm{R} - d)}{(\mathrm{H} - d - 2)} - 0.608} = \text{area to be stayed, sq. in.}$$

where

H = distance from tubes to shell, in.
d = distance DETERMINED [given] by formula in Par. 214.
R = radius of boiler head, in.

PAR. 243 IN THE CONSTANT C FOR MORISON FURNACES, CHANGE TO READ AS FOLLOWS:

C = 15,600 a constant for *Morison furnaces*, when corrugations are not MORE [less] than 8 in. from center to center and the radius of the outer corrugations is not more than one-half that of the suspension curve.

PAR. 247 REVISED:

247 Where NO RULES ARE GIVEN AND it is impossible to calculate with a reasonable degree of accuracy the strength of a boiler structure or any part thereof, a full-sized sample shall be built by the manufacturer and tested to destruction in the presence of the Boiler Code Committee or one or more representatives of the Boiler Code Committee appointed to witness such test. IN SUCH A STEEL-PLATE OR CAST-STEEL STRUCTURE, THE PRESSURE CORRESPONDING TO THE YIELD POINT SHALL BE ACCURATELY DETERMINED AND THE MAXIMUM ALLOWABLE WORKING PRESSURE SHALL NOT EXCEED THAT OBTAINED BY DIVIDING THIS PRESSURE BY 2.5. SUCH STRUCTURES WHEN OF CAST IRON SHALL BE TESTED TO THE BURSTING POINT.

PAR. 250 REVISED:

250 A fire-tube boiler WITH TUBES UNDER 5 IN. DIAMETER shall have [both ends of] the tubes [substantially] rolled and beaded, or rolled and welded at the firebox or combustion-chamber end, AND ROLLED AND BEADED AT THE OTHER END. IN THE CASE OF TUBES UNDER $1^1/_4$ IN. DIAMETER, THE TUBES MAY BE EXPANDED BY THE PROSSER METHOD IN PLACE OF ROLLING. IN THE CASE OF TUBES 5 IN. IN DIAMETER AND OVER, THE TUBES SHALL BE SECURED BY RIVETING OR OTHER APPROVED METHOD AT BOTH ENDS.

PAR. 252 REVISED:

252 The ends of all tubes, suspension tubes and nipples of water-tube boilers and superheaters shall project through the tube sheets or headers not less than $^1/_4$ in. nor more than $^1/_2$ in. before flaring. WHERE THE TUBES ENTER AT AN ANGLE, THE MAXIMUM LIMIT OF $^1/_2$ IN. SHALL APPLY ONLY AT THE POINT OF LEAST PROJECTION.

PAR. 253 REVISED:

253 *Drilling of Holes.* All rivet holes and staybolt holes and holes in braces and lugs shall be drilled [full size] or they may be punched not to exceed $^1/_4$ in. less than full diameter for material over $^5/_{16}$ in. AND NOT EXCEEDING $\frac{5}{8}$ IN. in thickness, and $^1/_8$ in. less than full diameter for material not exceeding $^5/_{16}$ in. in thickness [and then drilled or reamed to full diameter.] FOR FINISHING THE RIVET HOLES, THE plates, butt straps, braces, heads and lugs shall be firmly bolted in position by tack bolts for FINAL drilling or reaming TO FULL DIAMETER [all rivet holes in boiler plates except those used for the tack bolts.] THE FINISHED HOLES MUST BE TRUE, CLEAN AND CONCENTRIC. HOLES SHALL NOT BE PUNCHED IN PLATE OVER $\frac{5}{8}$ IN. THICKNESS.

PAR. 259 REVISED:

259 A manhole reinforcing ring when used, shall be of steel or wrought-iron, and shall be at least as thick as the shell plate THICKNESS REQUIRED BY PAR. 180.

PAR. 260 REVISED:

260 Manhole frames on shells or drums when used, shall have the proper curvature, and on boilers over 48 in. in diameter shall be riveted to the shell or drum with two rows of rivets, which may be pitched as shown in Fig. 21. The strength of manhole frames and reinforcing rings shall be at least equal to the tensile strength (REQUIRED BY PAR. 180) of the maximum amount of the shell plate removed by the opening and rivet holes for the reinforcement on any line parallel to the longitudinal axis of the shell through the manhole, or other opening.

PAR. 268 REVISED:

268 *Threaded Openings.* ALL PIPE THREADS SHALL CONFORM TO THE AMERICAN PIPE STANDARD AND ALL [a pipe] connections 1 in. in diameter or over shall have not less than the number of threads given in Table 8.

If the thickness of the material in the boiler is not sufficient to give such number of threads, the opening shall be reinforced by a pressed steel, cast steel, or bronze composition flange, or plate, so as to provide the required number of threads.

When the maximum allowable working pressure exceeds 100 lb. per sq. in., A NOZZLE OR SADDLE FLANGE [connection] riveted to the boiler to receive a flanged fitting shall be used for all pipe openings over 3 in. pipe size.

Par. 299 Revised.

299 [Nozzles and] *Fittings.* Flanged cast iron pipe fittings used for boilers, [parts,] for pressures up to and including 160 lb. per sq. in., shall conform to the American Standard given in Table [s] 16 of the Appendix, FOR PRESSURES UP TO 50 LB. and Table 17 FOR ALL HIGHER PRESSURES AND FOR STEAM, FEED AND BLOW-OFF PIPES UP TO THE STOP VALVE, except that the face of the flange of a safety valve as well as that of a safety valve nozzle, may be flat and without the raised face.

(Note. Balance of paragraph remains unchanged.)

Par. 307 Revised

307 *Blow-off Piping.* A surface blow-off shall not exceed 1½ in. pipe size and the internal and external pipes, when used, shall form a continuous passage, but with clearance between their ends and arranged so that the removal of either will not disturb the other. A properly designed brass or steel bushing SIMILAR TO OR EQUIVALENT OF THOSE [as] shown in Fig. 22, or a flanged connection, shall be used.

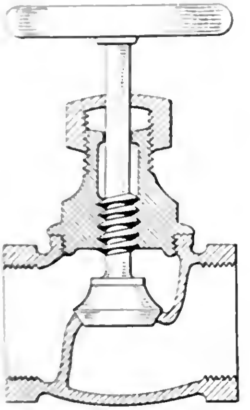

Fig. 22½: Type of Globe Valve

Par. 308 Revised:

308 Each boiler shall have a bottom blow-off pipe, fitted with a valve or cock, in direct connection with the lowest water space practicable; the minimum size of pipe and fittings shall be 1 in. and the maximum size shall be 2½ in. STRAIGHTWAY GLOBE VALVES OF THE ORDINARY TYPE AS SHOWN IN FIG. 22½, OR VALVES OF SUCH TYPE THAT DAMS OR POCKETS CAN EXIST FOR THE COLLECTION OF SEDIMENT, SHALL NOT BE USED ON SUCH CONNECTIONS. [Globe valves shall not be used on such connections.]

Par. 314 Revised:

314 *Feed Piping.* The feed pipe of a boiler shall have an INTERNAL DIAMETER NOT LESS THAN ¾ IN. [open end or ends inside of the boiler.]

Par. 325 Revised:

325 Lugs or brackets, when used to support a boiler of any type, shall be properly fitted to the surfaces to which they are attached. The shearing and crushing stresses on the rivets used for attaching the lugs or brackets shall not exceed 8 per cent of the strength given in Pars. 15 and 16. WHERE IT IS IMPRACTICAL TO USE RIVETS, STUDS WITH NOT LESS THAN 10 THREADS PER INCH MAY BE USED. IN COMPUTING THE SHEARING STRESSES, THE AREA AT THE BOTTOM OF THE THREAD SHALL BE USED. [For traction or portable boilers, studs with pipe threads may be used.]

Fig. 32 Revised:

A Change dimension line to center of stayrod.
D Change dimension line to center of staybolt.
F Change dimension line to center of door ring rivet.
H Give eighth sketch in drawing the designation "H."

Par. 423 Change Second Section to Read as Follows:

A bevel-seated 3½ in. valve WITH [is marked by the manufacturer] 0.11 in. lift HAS A [and] discharge capacity AT [for] 400 lb. pressure OF [=] 4840 lb.; hence two such valves would be required.

Par. 424 Change Second Section to Read as Follows:

A bevel-seated 2½ in. valve WITH [is marked by the manufacturer] 0.08 in. lift HAS A [and] discharge capacity AT [for] 275 lb. pressure OF [=] 6350 lb.; hence two such valves would be required.

Fusible Plugs.

Interesting Discussion at Atlanta Sessions

American Welding Society Assists in A.S.M.E. Spring Meeting Session on Welded Pressure Vessels—Professional Divisions on Fuels, Machine Shop, Management, Materials Handling, Power and Textile Coöperate in Program

SIX of the A.S.M.E. Professional Divisions coöperated in providing the technical sessions at the Atlanta Spring Meeting. The papers were all in hand by March 15 and this insured the printing and issue of the papers two weeks before the meeting. The resulting carefully prepared discussion added greatly to the interest and value of the technical sessions.

In accordance with the procedure of the past few years, a running account of the discussion is given in this issue of MECHANICAL ENGINEERING. Complete discussion will appear in the Transactions of the Society.

TEXTILE-MACHINERY SESSIONS

UNDER the auspices of the Textile and Machine-Shop Practice Divisions sessions were held on Tuesday and Wednesday mornings, May 9 and 10. At the first meeting two papers were presented: Cotton-Ginning Machinery, by S. E. Gillespie, and Maintenance of Textile Machinery, by E. H. Marble. On Wednesday three papers: Weaving Machinery, by L. B. Jenckes; Extraction of Oil from Vegetable Matter, by Jos. Davidson, and Modern Shop Practice in the Building of Revolving Flat Cards, by F. E. Banfield, Jr., were considered. All of these papers have been recently published in MECHANICAL ENGINEERING. H. M. Latham presided on both occasions.

In discussing Mr. Gillespie's paper, W. E. Caldwell[1] stated that the usual operating troubles encountered by cotton ginners are due to the too frequent use of set screws and clamped joints by the gin manufacturers instead of keys, to overloaded belts produced by the use of small pulleys and low belt speeds, and finally, to fans and their piping arrangement. The margin of safety on peripheral speed of fans in modern practice is too low. Air-blast gins have apparently been developed to accommodate the fans now on the market, whereas a fan should be designed to better meet the requirements of ginning systems. A fan somewhat on the order of the cupola blower, which has a better pressure-volume characteristic than the usual volume fan, as well as greater efficiency, might be advantageously employed, although the efficiency is relatively unimportant considering the low annual load factor of ginning plants. He asked whether the belt distributor had any real advantages over the pneumatic elevator, considering power saving, greater simplicity, ease of operation and saving of time between bales.

In another written discussion of this paper, A. W. Merkel[2] compared the single- and double-rib huller gins and presented figures on the power requirements of air-blast and brush gins. He also pointed out that while cotton gins are classed as agricultural implements, which as a class usually do not demand close machine work, the ribs, saws and space blocks which separate the saws, are parts necessitating accurate machining.

After the reading of the paper by Mr. Marble, the discussion was opened by R. A. Packard[3] who stated that the time must soon come when the lubrication of textile bearings will be done on a more efficient basis and while ball bearings on textile machinery are filling a great need today, the question as to whether they should supplant babbitt or brass friction metals is still unsettled.

W. H. Holby[4] discussed the subject from the ball-bearing manufacturer's viewpoint and in summing up his comments claimed that ball bearings require very little attention; that they effect a considerable saving in horsepower, varying with the application and type of machine; that savings in lubrication and maintenance costs are often sufficient to justify the entire expense of ball-bearing equipment, and that ball bearings improve the quality of the textile product.

The incorrectness of the idea that ball bearings are the cure for all operating troubles was then set forth by A. F. MacIntyre,[5] who advocated a specific remedy determined for and applied to each case rather than a general one for all ills.

Speaking from the viewpoint of the textile-machinery manufacturer, F. E. Banfield, Jr.,[6] said that there were certain bearings well suited for the application of ball bearings while others were not. On cards, ball bearings are not desirable since the properly designed plain bearing is simpler and will give less trouble in the long run. The average mill management puts too little importance on the subject of lubrication, whereas the life of a textile machine depends almost wholly upon the life of its bearings. Mr. Banfield placed roller bearings in the category of ball bearings, but considered them better suited for lineshafts, trucks, cranes or bearings subject to heavy loads and severe working conditions.

SECOND SESSION

The Wednesday session was opened by the presiding officer, Mr. Latham, who read abstracts from Mr. Jenckes' paper and described slides shown in connection therewith. In the discussion, C. H. Fish[7] questioned whether velvets are woven double and cut, since then, strictly speaking, it is not velvet but some type of plush. The distinct difference between the two is that plush is cut with a knife and not necessarily woven double and cut from the loom, while velvet, being much finer fabric, is cut as it is woven.

Mr. Davidson supplemented his paper with a detailed account of the development, operation and construction of his high-pressure yielding-plunger pump which gives a greater efficiency in oil extraction and saving in press cloth than with the hydraulic method. The discussion which followed centered around the cotton seed and the use and extraction of its oil on a commercial basis. The author stated that to every 1500 lb. of unginned cotton there was 1000 lb. of seed and the cotton-seed oil industry is secondary to the textile business in the cotton districts. From 1000 lb. of cotton seed 150 lb. of crude oil is obtained, and with the refining loss 6 to 10 per cent the net amount of refined oil is about 130 lb.

After explaining that picking or removing seed, leaf and other foreign matter from ginned cotton is the first process through which cotton is put in the mill and that carding is simply a further cleaning process to take out any short fly or staple which is undesirable in the making of a good yarn, Mr. Banfield presented his paper. He covered his subject very thoroughly and showed numerous slides. In the discussion, Mr. Fish called attention to the omission of mention of the old American drop card which was in use in this country prior to the production of revolving flat cards.

MATERIALS HANDLING SESSION

THE Materials Handling Division held its session on Tuesday morning, May 9, with R. M. Gates presiding. Only one paper, that entitled Material Handling Equipment as Used in the Iron and Steel Industry, by F. L. Leach, was scheduled. As the author is in India the paper was presented by F. L. Estep,[8] a former associate. The paper will be published in a future number of MECHANICAL ENGINEERING.

Mr. Estep read the entire paper and interspersed detailed ex-

planations of interesting features. He called attention to the soaking-pit crane and the charging machine. In the combination rail and structural mill described in the paper where the rolling of rails is one problem and the rolling of shapes another, he pointed out the equipment arrangement in complete units of angle table, cut-off, throw-off, skid table, gag straightener, double enders and double drillers. The mechanical doubler, which does the work more accurately than manual labor and has thereby been instrumental in reducing the cost of ten-sheet metal, received special comment.

Discussion Questions Answered

In answering questions raised in the discussion Mr. Estep said that he doubted if a machine could be invented to open the packs, since this is a problem of 75 per cent rolling and 25 per cent heat and the human element was needed. In a steel plant the wages are on a tonnage basis and therefore all equipment should be designed and constructed to meet the practical requirements of the workers and not to meet theoretical conditions. Handling and moving is a large item in the cost of manufacturing steel and steps are being taken to reduce it.

Stafford Montgomery[9] asked about economical methods for conveying and storing large quantities of many sizes of light tubes in the finished condition between drawing operations, also whether steam locomotives can be economically eliminated from the yard proper of a steel company and electrical power used. In reply Mr Estep stated that three or four methods can be applied in the handling of tubes between departments and storage between operations. A tube mill, as a rule, does not have overhead cranes in a big building but monorails can be installed which will quickly carry a good tonnage of hot or cold material. Or if it is cold tonnage, it can be handled with a magnet and a monorail. In regard to the question of steam against electricity, he said that the overhead-trolley system would interfere with the plant operation and a third-rail system, nine times out of ten, would be too expensive. Difficulties in the way of maintaining and safeguarding would offset the saving in operating economies.

E. L. Shaner[10] was of the opinion that the handling equipment in iron and steel plants could be divided into two classes, the largest of which is comprised of heavy and intricate machinery that requires the attention of engineers who specialize in that equipment. On the other hand, there are many operations which require simple mechanisms and hand labor, and the reduction of handling costs on these operations is of great interest to iron, steel, electrical and metallurgical engineers.

FIRST GENERAL SESSION

At the First General Session of the Spring Meeting, Edward R. Fish[11] presented in the absence of the author a paper on The Accuracy of Boiler Tests, by Alfred Cotton,[12] and C. C. Trump[13] a paper on Using Exhaust Energy in Reciprocating Engines which appeared in the June issue of Mechanical Engineering. Interest in the second paper was stimulated by the presence of Dr. Johann S. Stumpf, co-author of the paper and originator of the uniflow engine, who had investigated the principles set forth in the paper. The discussion of Mr. Cotton's paper appears directly after his paper in this issue, page 430. Earl F. Scott, of Atlanta, Manager of the Society, presided at this session.

Mr. Trump presented his paper with the aid of lantern slides which illustrated the important points he wished to bring out, and then introduced Dr. Johann Stumpf. Dr. Stumpf spoke of the uniflow locomotive which Mr. Trump had mentioned in presenting the slides. The uniflow locomotive, he said, had been in successful operation for a year. He described how he had changed completely the exhaust as usually designed, and told in considerable detail of the effect of an exhaust port designed to remove steam from the cylinder in the time available. He also spoke of the application he was making of this principle to a 6-cylinder automobile gas engine.

J. S. Coon[14] mentioned the hydraulic-ram analogy; and C. E. Coolidge[14a] told how the power of the Liberty motor had been increased by lengthening the exhaust pipe. J. T. Wikle[15] asked about the possibility of muffling a gas engine equipped with such an exhaust pipe. Mr. Trump pointed out that the exhaust pipe of such a design was in effect a muffler, and, in reply to a question by Roland B. Hall,[16] said that the gain in power of an ordinary steam engine had not been decided upon, as so far the only actual example in operation was that of the locomotive. The success with the locomotive pointed to gains in power at heavy load of over 10 per cent and at light loads of 3 per cent.

In answer to a question by Mr. Scott, Dr. Stumpf said that the greatest possibilities for gain lay with the gas engine rather than the steam engine, because the exhaust loss was larger.

In answer to a question about the gas turbine, Dr. Stumpf said that he considered the subject a serious one, and that he had the "most sincere pity for engineers who have to get up a gas turbine."

In answer to a question by Mr. Weaver, Mr. Trump said that the design of the exhaust nozzle was similar to the design of the turbine nozzle. It is simply to produce the velocity under the conditions of difference of pressure which exist during the exhaust period, this difference changing from instant to instant. In a multiple-cylinder engine the velocity can be used to produce a suction on another cylinder, but this is impossible in single-cylinder engines.

Donald B. Prentice[17] wrote that the paper suggested a fertile field of research for college laboratories.

FUEL SESSION

At the Fuel Session of the Spring Meeting three papers were presented: Reduction of Fuel Waste in the Steel Industry, by F. G. Cutler;[18] Boiler-Room Performance and Practice at Colfax Station, Duquesne Light Company, by C. W. E. Clarke,[19] and The Control of Boiler Operation, by E. A. Uehling.[20] Mr. Fred R. Low presided at the session. The first two of these papers have appeared in recent issues of Mechanical Engineering; Mr. Uehling's paper is published in this issue. A brief abstract of the discussion at the meeting follows.

Discussion of Mr. Cutler's Paper

Following the presentation of the paper by the author, a written discussion by F. J. Crolius[21] was read. He said that the author's suggestion of a method of balancing elements so that the smallest amount of added fuels will be consumed was an excellent one, but that there is at present no steel plant designed or operating with this objective in view. Fuels have always been an incident in production, he said, and conclusions based on present-day practice were of small value. He showed that, using figures of the best present-day practice, there is a deficit in the heat balance, although it is quite fair to assume that an ideal plant, designed with heat and power conservation in view, might be operated without firing additional fuel.

The author's suggestion of better-designed heating furnaces, while excellent for a projected plant, he said, was difficult to accomplish and hardly justified in the matter of investment. There was no question that heating furnaces, as usually operated, violated combustion laws, although these losses were small compared with others. Much might be done, he said, toward improving the conditions of operation which could result in saving heat.

R. S. Sage[22] and E. Pragst[23] presented a written discussion in which they said that apparently those primarily interested in the power and blowing plants of the steel industry are confronted with two entirely different classes of problems: one in plants where there is available an excess of gas, etc., above power and blowing requirement, so that the design of these machines need not be influenced by the question of plant thermal economy, and the other in plants where there is a shortage of by-product fuel or would be unless high thermal economy is possible. The writers then mentioned some of the advancements made in generating-station design which had direct bearing on steel plants belonging to this second class.

F. L. Estep[24] wrote that conditions in steel plants were far from being ideal, and that one of the outstanding features of the subject was that there was generally more to be gained by proper operation of existing equipment than by the installation of additional equipment. He criticized some of the author's figures which he thought were somewhat out of line with blast-furnace practice in general throughout the country. He thought an efficiency of 65 per cent more generally obtained than one of 60 per cent, that 1250 deg. was too high a hot-blast temperature, and that the assumption of 55 cu. ft. of air per lb. of coke left little margin for leakage. In the author's table of horsepower, the figures for total gas and total boiler horsepower seemed higher than in ordinary practice. He believed that net tons of coke consumed was a better basis than tons of iron produced for figuring expected horsepower. He thought the subject a very timely one and one which had not been discussed sufficiently.

Walter N. Flanagan[25] wrote that the use of blast-furnace gas was the keystone of power economy in the steel plant, as it was easier to maintain high efficiency when burning blast-furnace gas than when burning coal. A good burner was essential to efficient combustion, and a good gas cleaner was another source of saving. Dry-cleaning methods offered the greatest savings, he said, because the sensible heat in 400-deg. gas was worth $22,000 per furnace per year in equivalent coal. Coke breeze screened out of the blast furnaces was being used successfully in plants. When burned in underfeed stokers, coke would produce slightly more than half as much steam per pound as good coal.

W. Trinks[26] wrote that there was danger that the conclusions drawn from the author's paper might be generalized and that readers might gain the impression that an economical blast furnace and steel plant could operate without coal and still use steam blowing equipment. The coke consumption of 2500 lb. assumed by the author was high for northern plants, he said, where 1800 lb. per ton of pig iron was a more reasonable figure. The effect of such a reduction in coke consumption was to decrease both the quantity and the heat value of the gas. As regards open-hearth furnace practice, he said, northern plants were using approximately equal quantities of hot pig iron and scrap, so that a ton of pig iron would certainly produce at least 1.5 tons of steel, which would result in a greater heat demand. The total effects would show a net deficiency of over 17 million B.t.u. per ton of pig iron, which must be supplied by the burning of coal. As the matter stands today, he wrote, he knew of no low-coke-ratio plant with blooming and finishing mills in which the blast-furnace and coke-plant fuel sufficed for the whole plant, unless gas blowing engines were used.

The author replied to the discussion as follows: "Mr. Crolius apparently overlooked the intention of this method of comparison of blast furnaces. He goes into some detail in showing that one plant will vary from another, and how this difference will be caused, depending on the type of equipment used.

"That is one view of the comparison, it is true, but there is no reason why the same plant cannot be compared day by day by the method suggested in the paper.

"He also stated that he did not believe it would be advisable to improve existing heating furnaces. In that respect I beg to differ very strongly with Mr. Crolius, as we have found that it is very necessary to improve the existing heating furnaces.

"Mr. Trinks brings out a formula in which he shows that the heat available from the gas per ton of iron varies materially with the coke consumption and is less than that given in the paper. The only difference between the figures is that the author uses 2500 lb. and Mr. Trinks 1800 lb. of coke per ton of pig iron. The author believes that the average lies between these figures and that 2500 lb. is closer to the average coke consumption of all furnaces in operation.

"Mr. Trinks also mentions the fact that in some open hearths a large percentage of scrap is used. This may be true for the particular furnaces that he has in mind, but if this ratio is maintained, practically one-third of the pig-iron steel would have to go back into scrap in order to make some more open-hearth steel.

"In regard to the point raised by Mr. Estep as to the omission of the allowance for leakage, the author's position is that leakage bears the same relation to inefficiency in either gas or coal, and it does not make any difference to the whole gas-furnace plant whether the gas inefficiency is in the boilers or stoves; or in throwing it away in the top of the furnace. The whole question resolves itself into how much can be got out of the surplus gas. We all differ in our assumptions. The figure of 55 cu. ft. per lb. of coke includes an allowance of probably 10 per cent of the theoretical figure, which is between 50 and 55 in most cases, and 55 includes a percentage for leakage."

Discussion of Mr. Clarke's Paper

Nevin E. Funk[27] opened the discussion of Mr. Clarke's paper by stating that one of the basic principles of power-plant design was that the simplest control consistent with best results should be obtained. This led him to criticize the use of two motor drives on the clinker crusher. He was convinced, from his own experience, that best results were obtained by continuous operation of the rolls, the speed varying with stoker speed. It was possible, he said, to eliminate the necessity of using water in the clinker-crusher pits. He said that the pits in the Colfax plant were too shallow to operate without water, and that the V-shaped sides acted as the buttress for an arch across which clinker would flux and hang unless cooled by water.

He asked if there might not be a possibility of error in the figures for the efficiencies of No. 8 boiler in September and No. 5 boiler in January and February. If such efficiencies could be maintained for a while, he asked, why not all the time with careful operation?

He spoke of the low superheat mentioned by the author and offered as an explanation the suggestion that in a low-set boiler secondary combustion might play a considerable part. With the advent of the more efficiently designed furnace, the heat available at the superheater, as well as the heat transfer rate, would be reduced, and more surface or a rearrangement of gas passages would be necessary to obtain the results expected.

B. N. Broido[28] said that the performance of the boilers at Colfax was of interest because of the large number of 1500- and 2000-hp. boilers now being installed or under consideration. The design of boilers had changed very little, he said, in the last few years, and it seemed that all efforts were being concentrated in the improvement of accessories. He discussed the subject of superheaters in considerable detail.

T. E. Keating[29] said that the paper showed what could be accomplished with modern high boilers and underfeed stokers without the aid of such heat reclaiming apparatus as economizers and air preheaters. He pointed out that the figures represented operating performance and should not be compared with a boiler test, in the common interpretation of the term. He discussed the combustible in the ash and the relation between mechanical and thermal conditions in stoker operation. He showed that time required for boilers to reach the point of maximum efficiency had

been reduced from over seven to under two days, and the effect this had on average monthly efficiency.

D. Robert Yarnall[30] discussed the measurement of hot boiler feedwater, saying that his experience had showed him that the V-notch-weir method of measurement was extremely dependable, because it was accurate at low as well as at high rates of flow, because it compensated automatically for variations in temperature and because of the hydrometer action of the float which operates the recording mechanism.

The author replied to the discussion in part as follows: "In reference to the comments of Mr. Funk about the double drivers on clinker grinders, these grinders are about 30 feet wide, and at the time of designing them it was thought best to drive both sides. The clinker operation resulting from this design has justified the designers' ideas on that subject.

"As to the speed of the rolls, we never have been able to run the rolls slowly enough Running the rolls even as slowly as four revolutions an hour is quite fast. The rate of speed of the clinker grinder depends entirely on the ash bed over it. If it is ground at too great a speed, the clinker grinder is burned out. We expected to make an improvement in the use of water in the pits. It has been found absolutely necessary to maintain flowing water in the pits to avoid losses in efficiency and other troubles due to clinkers.

"To touch again on the comparative efficiency of boilers No. 5 and No. 8, we have had an actual difference in this plant of over 10 per cent between adjacent boilers. When ferretted out, we find a certain type of ram, which is less efficient than another, and when we consider these high efficiencies we find many things to consider in stoker temperature. The boilers are not identical, neither are the efficiencies identical. In any boiler plant the size of this, two or three per cent difference in efficiency can be found in the boilers if operated at the ratings given. The man who is running a particular boiler has something to do with this difference. We have never found any of the meters on the boilers with an inaccuracy of over one per cent. The average difference in accurate value of the meters by actual test has been about 0.07 and never over 1 per cent.

"The superheat is low in the original boilers, due to heat absorption through the machine prior to the superheater.

"As to the lowering of oxygen in the barometric heater, we are trying some experiments of putting a slight vacuum on the barometric head, to see what can be done in the way of dilution which will remove the air, and also in heating the feed tank where most of the absorption takes place.

"At the time the plant was built coal was selling at $2.35 at Pittsburgh. We realized that the price of coal was going up, so that $3.50 was the rate assumed for a period of ten years. At that rate, and with the construction costs prevailing at that time, the economizers would begin to pay for themselves when coal reached $7.00 a ton.

"There were two questions regarding oxygen elimination. The oxygen elimination in that heat-balance system involves two factors, which are more accidental than otherwise. It is perfectly natural that there would be a lower value than the theoretical in a cycle in operation.

"Another feature is the time element which is necessary for absorption. We have no special means for oxygen elimination other than what occurs due to the heating, which drives out the oxygen. We are now trying some means of infiltration which will lower the heat further.

"In answer to Mr. Hutchins' comments on the maximum boiler rating, these boilers operate normally from 130 to 210 per cent of rating during the day of 24 hours. We have run them on test as high as 313 per cent for four or eight hours, but the average would be around 175 per cent.

"For February, March and April the total output of the plant was estimated at 97,575,100 kw-hr., and the load factor was 77.5 per cent. This station is operating on the base load as much as possible and the B.t.u. rate per kw-hr. average output, for the months of February, March and April, was 18,713.

"In answer to Mr. Trinks' comment as to air and coal control, some persons think that coal and air can be controlled automatically. It cannot be done. The air is controlled automatically, and the coal by hand.

"In answer to Mr. Bailey's comment regarding the overheating of the superheaters, in the new location it would be impossible to overheat the superheater by any change which did not bring about additional stresses over and above those of the cycle for which the superheater is planned, and if there was an element causing an increase in temperature it would cause overheating in the metal.

"As to Mr. Carter's question on the measurement of flue gases, we use mercurial pyrometers for these readings. We have tried others, but not with satisfactory results.

"In answer to Mr. Davis' question, the baffles are the standard B. & W. baffles, brick-backed, with cast-iron supports. We are going to try these baffles on some additional boilers. We use only the cast-iron baffles. We do not use any poured baffles."

SECOND GENERAL SESSION

At the Second General Session of the Spring Meeting, held on the morning of May 10, four papers were presented: Centrifugal Castings, by Leon Cammen; The Muscle Shoals Plant and the Nitrogen Supply, by Major J. K. Clement, presented by George A. Orrok; Heat Losses from Bare and Covered Wrought-Iron Pipe at Temperatures up to 800 Degrees Fahrenheit, by Russell H. Heilman, and the Evaporation of a Liquid into a Gas, by W. K. Lewis. Major Clement's paper appeared in the June issue of Mechanical Engineering. The papers by Mr. Heilman and Professor Lewis are published in this issue, while Mr. Cammen's paper will appear in an early number. W. S. Finlay, Jr., Manager of the Society, presided. A brief account of the discussion follows.

Discussion of Mr. Cammen's Paper

W. M. Corse wrote that engineers should be interested in centrifugal casting because commercially it was so practical. The speed of production far exceeded that of ordinary sand molding, he said, and the quality of the product was superior.

James B. Ladd[31] regretted that the author had not emphasized the extreme difficulty of making successfully castings by the centrifugal process. He felt that no engineer should undertake to develop the process without knowledge of these difficulties. It should be noted, he said, that a commercially perfected centrifugal process not only produced a product competitive in cost and quality with like products by other processes, but usually the centrifugal product was of superior quality.

Discussion of Major Clement's Paper

In the discussion which followed his presentation of Major Clement's paper, Mr. Orrok[32] said that his experience had shown that water-power plants would pay interest whenever the cost was less than $120 per kilowatt of machinery installed. He had known of plants costing as high as $500 per kilowatt. These plants had begun to pay interest only after the original investment had been written off, that is, after the original stockholders had lost their money. Since the increase in the price of coal, it was possible, he said, to pay as high as $200 per kilowatt and compete with steam plants, but $400 per kilowatt could not be invested with profit. Muscle Shoals, he said, was a very costly water-power development. At the present time no one could say what the cost of the plant would be, but it was his opinion that it would be in the neighborhood of $400 per kilowatt.

W. S. Finlay, Jr.,[33] chairman of the meeting, spoke of the necessity of keeping the Muscle Shoals plant so that it might be available in case of war.

Mr. Orrok said that the South was full of by-product industries, but he had heard no discussion of ammonium sulphate. Ammonium sulphate, he said, was pretty well known; it was produced regularly and at present commanded ready sale. Other nitrogenous compounds in the by-products from the distillation of coal, cyanides, are almost invariably thrown away. He did not have personal knowledge of one plant in which there was an attempt made to save the cyanides. An amount of cyanide is allowed to escape today in the United States equivalent to double

the output of the Muscle Shoals plant in fixed nitrogen, but commercially it is not worth saving.

There is one other point of view that should be remembered in connection with the Muscle Shoals plant. That plant was designed three or four years ago. Today it is practically ancient history. The process has developed so much that if the plant were to be used it would have to be reconstructed. If the plant waits another four years it will probably have to be rebuilt entirely, and by 1930 fixed nitrogen will probably be made in a very differently designed plant.

Dr. Stumpf spoke of the plant built in Germany during the war for the manufacture of nitrogen products. Since the end of the war it had been reconverted in an astonishingly short period for the manufacture of fertilizers.

The discussion of Mr. Heilman's paper appears directly after his paper in this issue, page 437.

The paper on The Evaporation of a Liquid into a Gas was presented by title. Written discussion was presented for record in the Transactions of the Society.

MANAGEMENT SESSION

On Thursday morning, May 11, the Management Session was held under the auspices of the Management Division with L. P. Alford, Vice-President of the Society, in the chair.

After the Committee on Management Terminology, which is made up of representatives from the Society of Industrial Engineers, Industrial Relations Association of America, National Association of Cost Accountants, Taylor Society, American Institute of Accountants, and the Management Division, rendered its report, the two papers, Management Applied to Textile Plants, by George S. Harris, and The Southern Worker—His History and Character, by Frank H. Neely, were presented. The former was published in the June issue and the latter in the May issue of Mechanical Engineering.

Both papers were discussed together. J. A. McPherson[34] believed that a good part of the success of the southern mills was due to the close contact of the management with the employees, while in a written discussion, Charles H. Eames[35] predicted that the management of the textile mills of this country will continue to be more and more in the hands of broadly trained manufacturers who are essentially textile engineers. He termed managerial ability as an amalgamation of natural intelligence, educational training, personality and experience.

C. M. Bigelow[36] believed that the success of a mill was greatly dependent upon a properly maintained mechanical department, having an adequate storage of repair parts, mechanical supplies, etc., and a gang of repair men who could promptly handle emergency repairs, but whose overhead cost would be absorbed by continuous work along routine repairs, machining of repair parts, etc. Mr. Bigelow differed with the author and considered that too much emphasis is put on the technical ability of the department heads and not enough on their purely managerial responsibilities.

In a written discussion Frank B. Gilbreth[37] stressed the points that there is one best way for performing any operation and that the various conditions in the textile mills have not been properly studied in general in order to produce superintendents by which one best way may be discovered and put into effect.

In the last of four written discussions read by Prof. Eaton Webber of the Georgia School of Technology, E. A. Lucey[38] advocated a study of conditions and individual training of the workers by a specialist. Although this training is expensive, it pays for itself from the start and later dividends by establishing a better understanding between the management and the employees. Also after this instruction in the best way to do the work, the difference in the amount of work done between the poorest and the best workers should not be over 15 to 20 per cent.

Frederick McDonald[39] called attention to the recently published book entitled Waste in Industry, which placed 50 to 80 per cent of the waste on management and charged the latter with responsibility for improvement. He also urged the training of the mental equipment of workers and a realization that management is not only the problem of the men at the head of the organization, but of every individual who directs some one under him as well.

C. H. Fish[40] pictured the transition during the past twenty years in the nationality of the labor in the northern cotton mills and the utter impossibility of treating the present-day conglomeration of nationalities and classes in the same way as the southern worker. Also since the northern mills were built first, the southern manufacturer has avoided their mistakes and shortcomings.

In the closures, Mr. Harris pointed out the need of standardization before the American manufacturer could compete in foreign markets and the wonderful opportunity before the Society to accomplish the task through its officers and committees. Mr. Neely was opposed to involving workers, who were usually of inferior mental capacity, in the responsibilities of management, but considered it very much better to develop the managerial control.

POWER SESSION

At the Power Session held on Thursday morning, May 11, D. W. Mead presiding, three papers were presented, namely: Economics of Water-Power Development, by C. A. Mees; Power Development in the Southeast, by Chas. G. Adsit, and Hydroelectric Power-Plant Design, by John A. Sirnit. Mr. Mees' paper appears in this issue. Mr. Adsit's paper was published in the May issue of Mechanical Engineering and Mr. Sirnit's paper will appear in an early number.

In a written discussion of Mr. Mees' paper L. A. Magraw[41] pointed out that steam-power plants could be developed in units as the demand grew while water-power plants are constructed complete in the beginning with the result that often heavy losses are sustained by the latter during the early period of operation when the load is considerably less than the capacity of the plant. Regulatory bodies have not given the proper consideration to these deficits and instead of determining the allowed revenue upon replacement cost, new, less depreciation, have attempted to determine the cost in prewar times plus the additions since that time. Then from this historical value of the property is deducted the accrued depreciation arrived at by comparing the physical condition of the plant at the time of the rate inquiry with a similar plant new. This is simply an arbitrary way of reducing the value of the property for rate-making purposes and has no relation to the market and economic conditions in the territory, which should fix the rates.

A. A. McLeod[42] in referring to written instructions for employees, said in his experience that the way to get the best service is to aid the employee in every possible way to discover the fact that he has a brain and then he will use it.

Geo. A. Orrok[43] considered it unfortunate that Mr. Mees adheres to the idea of primary and secondary power. Primary power cannot be sold or used as no one today has a 100 per cent load factor. Those having to do with pulp making or metallurgical projects may have an 85 or 87 per cent load factor, but most plants must be content with a 50 per cent load factor and this is not primary power or even secondary power. Mr. Orrok stated that kilowatt-hours and not kilowatt-years are the units of sale of power.

Chairman Mead emphasized the importance of the economic advisability and justification of any water-power project. These must be established before the project is built.

In closing Mr. Mees called attention to the value of written instructions not only to employees but also to the person preparing the instructions. He decried the use of any other unit but the kilowatt hour for the sale of power, but he reiterated the fact that

there are two classes of power: one that must be available at any and all times, and the other in which there is some latitude in delivery.

Hydroelectric Power Development

In connection with the presentation of his paper, Chas. G. Adsit showed some airplane views of the water-power development and a moving picture of a portion of the construction of the Burton Dam. This is a cyclopean dam with gravity section, 1220 ft. long and about 125 ft. high. Its reservoir has a shore line of about 63 miles and contains 5,500,000,000 cu. ft. of water. This water now falls 608 ft. and delivers about 55,000,000 kw-hr. but will eventually fall 1220 ft. Another reservoir with a 24 mile shore line contains 1,400,000,000 cu. ft. and on present development has 15,000,000 kw-hr. capacity. The Tallulah Falls diversion dam is 360 ft. long and 116 ft. high and is built on a radius of 900 ft. A tunnel, 12 by 14 ft., runs a mile and a half through a mountain with a fall of 12 ft. and ends in penstocks that drop to the Tallulah Falls plant of 108,000 hp. capacity. A new development under construction at Tugelo will have a dam 150 ft. high and in the plant will be four 20,000-hp. turbines and four 12,500-kw. generators.

In the discussion which followed Oscar G. Thurlow[41] pointed out the valuable location of the Muscle Shoals hydroelectric power project for serving a region which, compared with other sections of the Southeast, has suffered in its industrial development because of lack of power. There is a market now available for the disposal of the primary power and a chemical plant to use a great part of the secondary power, so that with a general distribution of the Muscle Shoals power an industrial advance in this region would naturally follow.

F. P. Cummings[42] gave the details of the emergency in 1921 which the power companies of Tennessee, Georgia and the Carolinas were only able to meet through the interconnecting of the systems, and finally how the leasing for one year of the 60,000-kw. Government power plant at Sheffield, Ala. has insured power service to many industries that might otherwise have been compelled to curtail their production during the low-water period, and provided power services for industrial expansion in this territory.

Prof. C. S. Brown[43] decried the power that was being lost every day at Muscle Shoals because of its incomplete development and Mr. Orrok commented on the mean flow of the Tennessee River and the total fall of water available there.

Mr. Adsit, in his closure, reiterated the statement in his paper that Muscle Shoals is good for about 100,000 hp. in primary power and an undeterminable amount of secondary power, and said that the minimum flow of the Tennessee River is probably around 5500 second-feet.

The last paper of the session was given by Mr. Sirnit, who described his subject as an improvement in the design of an hydroelectric power plant which will not only give more kilowatts but kilowatt-hours without any additional cost. By ingenious application of the kinetic energy of the water, action similar to an ejector is obtained, and the normal tail water is raised at the same time the head on the machine is increased. The details of tests of models of the Thurlow suppressor then followed and in conclusion a description of the development now under construction incorporating the idea.

Mr. Adsit commended this new application of the idea and believed that engineers would eagerly await the operation of the plant.

SYMPOSIUM ON WELDING

THIS symposium was arranged under the joint auspices of the A.S.M.E. Boiler Code Committee and the American Welding Society to supplement the public hearing on the proposed code for unfired pressure vessels held at the Annual Meeting last December. Four papers were selected for presentation. These papers were: Strength of Electrically Welded Pressure Containers, by R. J. Roark; Some Principles of the Construction of Unfired Pressure Vessels, by S. W. Miller; Steel for Forge Welding, by F. N. Speller; and Tests on Welded Cylinders, by E. A. Fessenden and E. J. Bradford. The dire need of a code was indicated by the numerous communications, acknowledging meeting announcements sent to interested manufacturers and individuals, which urged action. Mr. Roark's paper was published in the April issue, and Mr. Miller's in the June issue; Mr. Speller's is printed in this issue of Mechanical Engineering and the fourth will appear in a later number.

Edward R. Fish, who presided at the session, is Chairman of the A.S.M.E. Boiler Code Sub-Committee on Air Tanks and Pressure Vessels. In his opening remarks he reviewed the status of welding pressure vessels.

The discussion at this session was of such general interest and so much new material was submitted that a more complete treatment of the discussion will be presented in the August issue of Mechanical Engineering than is customary with meeting discussions.

Stainless Steel

Below is given a brief list of references of Stainless Steel supplied to Mechanical Engineering by the Engineering Societies Library as data that might prove of value to its readers:

The Engineer and World Problems

America and the Rehabilitation of Europe was the general topic of the twenty-sixth Annual Meeting of the American Academy of Political and Social Science held in Philadelphia May 12 and 13. For the six sessions, various aspects were discussed under the subtopics: The Industrial and Financial Situation in Europe and Its Remedies; To What Extent is America's Prosperity Dependent on the Rehabilitation of Europe; America and the Debts of Europe; America and the Political Situation in Europe; Is America's Coöperation Indispensable to European Rehabilitation; America's Relation to the European Situation.

Alfred D. Flinn

Men and women from Europe and many parts of America were the speakers and treated the subjects from first-hand knowledge. Large audiences of thoughtful persons listened intently to all the papers and discussions.

Diplomats, business men, bankers, statisticians, representatives of Labor and the press, men experienced in governmental service, a manufacturer and an engineer, alike, presented, in the main, the economic and political phases of the topic. Russia and the Genoa Conference received much attention, as well as payment of international debts, upbuilding of mutual confidence among peoples, and stabilization of industrial, political and financial conditions.

In a broad way, all the papers were of interest to engineers. With one notable exception, however, the speakers referred but incidentally to the parts of the engineer, the scientist and the educator in the solution of present-day world problems. In the main, the speakers dealt with the mechanisms of industry, trade and government to the exclusion of fundamental principles, such principles as were dealt with being, for the most part, the rules of trade. Only by scant implication was there recognition of the mighty mental forces newly developing the world's resources, both physical and intellectual, through science and technology, or of man's increasing endeavors to know and use more effectively both his mental and physical capacities. Counting-room, rather than laboratory, supplied the tests for acceptability of proposed solutions of the world's problems.

The notable exception to which reference was just made, was the address of Dr. B. Stepanek, Minister at Washington of the Czecho-slovak Republic. He appealed for the establishment in Central Europe of a great American university and library as a center from which could be given out the best products of American culture, a source of correct information about America and of the best American ideas. He pleaded, also, for some influential alliance of the engineers of all countries—a World Federation of Engineers—through which this constructive type of mind could be brought more effectively into the service of the nations. He suggested that at an early date, there should be an international conference of such men, rather than of politicians and of statesmen, bound by tradition and self-seeking nationalism—a conference of constructively-minded men who could take fresh views of the world's condition, deal scientifically with fundamental causes, and suggest impartial, far-sighted plans for continuing progress.

But the politician yet holds the reins of government. Will he give the engineer a chance to contribute in any large measure to the direction of national and international affairs? What can the engineer do by way of preliminary demonstration of his capacity to deal with problems which need the engineer's loyalty to facts, power to analyze, and enthusiasm for construction, but which are not amenable to slide rules and instruments of precision? It is certainly noteworthy that a man, trained to diplomacy from his youth and who has devoted his life to that calling, should so insistently urge participation of the engineer in present-day problems of state. Is he not right, for have not the engineers and scientists, by their wonderful advancement of physical and intellectual development of the world, brought about social and industrial conditions with which statesmen and politicians are not yet prepared to deal?

How can Dr. Stepanek's remarkable suggestion, repeated on several occasions, be put into effect? Why not a "trial trip," in the parlance of the marine engineer, a joint convention of the great national American societies of engineers in Europe in the summer of 1923, to meet engineers of all the countries of Europe for discussion of such of the world problems as may be most vulnerable to engineering attack?

The meetings of the Academy were important and cannot fail to have widespread effect upon public opinion in the course of time. In the future, engineers should have places on the program and do their share in studying such subjects as the Academy selects for its meetings.

Alfred D. Flinn.[1]

Coöperation in Standardization—An Opportunity for Engineers

As a direct result of the report of the F.A.E.S. Committee on Elimination of Waste, Secretary Hoover instituted a countrywide program of simplification in sizes and varieties of commodities in general use, such as paving brick, axeheads, shot-gun loads, etc. To carry out this work properly, he established the Division of Simplified Practice in the Department of Commerce and placed at its head W. A. Durgin, formerly of the Commonwealth Edison Company of Chicago.

The American Engineering Standards Committee was organized in 1918 by the national engineering societies for the purpose of coördinating the standardization activities of the various engineering groups and industrial associations of this country. It also furnishes a valuable contact with the standardization work of foreign countries. This Committee has now developed into an organization with one hundred and sixty coöperating bodies and has established a noteworthy plan of procedure that provides for the absolute autonomy of the member bodies in standardization work. The success of the Committee's plan of procedure is fully demonstrated by the rapid increase in number of member bodies and by the fact that, to date, twenty standards have been approved and fifty standardization projects are in process.

To insure coöperation between these two organizations having

---

[1] Mr. Flinn, Secretary of the United Engineering Society, was appointed Honorary Vice-president to represent the A.S.M.E. at the Twenty-sixth Annual Meeting of the American Academy of Political and Social Science.

similar objects but different fields, as will be explained later, Mr. Durgin has been appointed a member of the American Engineering Standards Committee and A. A. Stevenson, a former chairman of the American Engineering Standards Committee, has been appointed as a member of an Advisory Committee to the Division of Simplified Practice.

The American Society of Mechanical Engineers is coöperating with the American Engineering Standards Committee through its delegation of three representatives. E. C. Peck, Chairman of this delegation is also Chairman of the A.S.M.E. Standing Committee on Standardization.

It is obvious, that to carry out an economical program of standardization, there must not be duplication on the part of this new activity of the Department of Commerce with the established American Engineering Standards Committee. It is well recognized that in the field of standardization the American Engineering Standards Committee is the logical body. This field embraces all projects which are of special interest to engineering and associated industries. The Division of Simplified Practice agrees not to enter this field. It desires to develop, however, a field of broad usefulness by reducing the number of sizes and by simplifying the varieties of manufactured articles in common use.

On May 4, Secretary Hoover invited the American Engineering Standards Committee to solicit the coöperation of its member bodies in a canvass to determine what simplification of manufactured products is most needed and most desired at this time. On May 22, the American Engineering Standards Committee unanimously accepted this invitation and voted to urge the immediate and active coöperation of the member bodies in carrying on this canvass. In accord with this action of the American Engineering Standards Committee, the Standardization Committee of the American Society of Mechanical Engineers met on June 13 jointly with some of the Society's members who served on the Waste Committee. This joint body recommended to the Council of the Society that immediate steps be taken to secure the suggestions desired by Secretary Hoover from the membership of the American Society of Mechanical Engineers. To this end the Society's membership has been addressed through the eleven Professional Divisions. Prompt replies have been requested as it is desired to place the suggestions of the membership in the hands of the Department of Commerce as soon as possible. Publicity has also been given in the June 22 issue of the *A.S.M.E. News*.

Every reader of Mechanical Engineering should realize his personal obligation to use his knowledge and experience in securing suggestions of manufactured products that will permit of simplification or standardization. This request of Secretary Hoover should be an incentive to the engineering profession to contribute a service it is eminently fitted to render. Give thought to the common manufactured articles that you touch and see daily and consider the possibilities of simplification or standardization. Send in the results of your study at once and you will have assisted materially in this sincere effort of the Secretary of Commerce to reduce in some measure the present wastes in industry.

Science for the Layman

As the life of the engineer is spent in applying the principles of science to the improvement of our condition, he should, above all others, be interested in the wide dissemination of accurate information concerning science among laymen, and should therefore give a hearty welcome to the recently published "Outline of Science." Here is a popular account of the essentials of present-day science, long enough to cover the outline, yet not long enough to be tiresome, eminently readable without attempting to be sensational, and amply and intelligently illustrated. The work is edited by J. Arthur Thomson, regius professor of natural history in the University of Aberdeen, whose standing vouches for the accuracy of the text.

After the flood of books of "popular" science that has recently emanated from so many unskilled pens, it is a pleasure to call attention to one that reports the latest opinions of authority, in a form suitable for young and old alike.

Harrison W. Craver.

Making a Start in Government Reorganization*

The continuance of great Government expenditures has shown the impossibility of cutting appropriations and payrolls to any great extent except by substituting sound business methods for wasteful and extravagant procedure. The first step needed in effecting this improvement must be to make thorough reorganizations, grouping under distinct departments those functions or activities which are of similar character or should logically be coördinated.

The business administrative methods of the Federal Government have no satisfactory provision for planning a department. Each bureau covers as much ground as is permitted by its construction of the authority received by it. The result is that many bureaus duplicate the work of others by doing much the same type of work. For instance, in the engineering and construction work of the Federal Government there are twenty-seven different agencies engaged in building construction, sixteen in road construction, nineteen in hydraulic construction, twenty-two in engineering research, twenty-five in surveying and mapping, six in coast fleets, sixteen in work on rivers, ten in public-land functions, and fifteen in chemical investigations.

Obviously there is need of a controlling agency to allocate specific work to each bureau, make it operate within prescribed limits and insure that its work supplements that of the others. This state of affairs is typical of conditions existing in other Government activities.

Engineers in touch with Government business methods and knowing the waste resulting from present practice, have for many years discussed plans for bringing together into one existing Department, all the commonly known Public Works. As a result, delegates from seventy-four engineering, technical, and business societies, with a combined membership of over one hundred thousand met at Chicago in April, 1919, and founded the National Public Works Department Association. Its object was to establish in the Federal Government a systematic, businesslike organization to carry out public works, similar to that in use by private concerns and by practically all other important nations.

The Association, whose task has been taken over by the American Engineering Council of the Federated American Engineering Societies, proposed no radical reorganization, additional Government Department or Cabinet officer. It advocated that the Department of the Interior be changed into the Department of Public Works, that bureaus in other Departments engaged in public works be transferred to this Department, and that Interior Department bureaus not so engaged be placed elsewhere.

The adoption of such a plan is essential to the success of a budget system in national works. It would reduce taxes by cutting down overlapping activities, and minimizing the duplication of work. The proposal serves the interest of no class, has no politics and is absolutely non-partisan.

A bill known as the Jones-Reavis Bill, providing for these changes, has been introduced in Congress and is securing general support.

Howard Monroe Raymond Heads Armour Tech.

On May 23, 1922, the Board of Trustees of Armour Institute of Technology announced the appointment of Dr. Howard Monroe Raymond as President of that institution. Dr. Raymond has served as Acting President of the Institute since the death of Dr. Frank W. Gunsaulus last year, and has also been Dean of Engineering since 1903.

President Raymond is well known in the educational and engineering world through his activities at the Institute during the past twenty-seven years. He is a graduate of the University of Michigan and a member of leading engineering and scientific societies.

His appointment to the presidency of this rapidly developing engineering college assures to its students and alumni a continuation of progressive plans for the future of the institution.

---

* Extracts from a Statement by Francis Blossom, Chairman during the War of the Board of Review of Construction of the War Department, and Representative on the American Engineering Council of The American Society of Mechanical Engineers.

Ambassador Jusserand and Secretary Hoover Attend Engineers' Dinner

In furtherance of its desire to cultivate camaraderie between French and American engineers, the American Section of the Société des Ingénieurs Civils de France entertained at dinner on May 29 the members of the deputation of American engineers who carried the John Fritz Medal last year to Eugene Schneider.

The dinner was given at the University Club in Washington. Herbert Hoover, Honorary President of the American Section of the Société, presided. The guests included, Ambassador Jusserand of France and the presidents and secretaries of the four Founder Societies, the United Engineering Society, the Federated American Engineering Societies, the Engineering Foundation, and the John Fritz Medal Board of Award. Dean Dexter S. Kimball, President of the American Society of Mechanical Engineers, was represented by Leon P. Alford. Regrets were received from Dr. Ira N. Hollis, Robert A. Cummings, F. L. Hutchinson, Dr. Wm. McClellan, and Dr. F. B. Jewett.

In speaking of the work of engineers, Ambassador Jusserand pointed out a marked difference between American and French engineers. The former have at their command colossal natural resources, the latter but limited resources. This has tended to make Americans careless. "They rush into their work with full steam on," he said. "All is hustle and bustle; they want results regardless of effort or expense; they waste their resources in reaching their ends. The French engineer is careful and cautious; each step is carefully calculated: there is nothing to waste, and hence nothing is wasted. And I believe," he added, "that in the end neither has much the advantage." "I think it is shameful the way you treat your locomotives. You build them strong and powerful; you put any driver into them and he runs his engine simply as a powerful machine to get results, and when the results are secured, the engine goes to the scrap heap. Our engines are built like a watch. They are cared for as a race horse, each by its own driver who is as careful of it as of any live thing, and who regards it as his child to be watched and cared for and tended through a life that may continue for many years."

"It is a mistake for us to send our young men just out of college to get their early practice training in this country. Your conditions are so different from ours; so it would be a mistake to send your young men to us. But after each has had training in his own country long enough to become acquainted with local conditions, then the study abroad is most valuable, in order that each may have the opportunity of learning those things which may be adapted to his own home conditions."

Aimé Dumaine, President of the American Section of the Société, then read several cables from France, among them one from the President, felicitating the Section on its happy idea of holding this joint meeting, and another from Marshal Foch, the only member of all societies represented, congratulating the Societies on this occasion, which he hoped would be the forerunner of many more similar gatherings.

M. Dumaine spoke of the friendship and respect which had grown up during the war between the engineers of the two countries. "Nothing must come to destroy this," he said, "and by our united action we can not only preserve it, but we can develop the same feeling between other professions and between the people at large.

"Ambassador Jusserand has been working for twenty years to establish and maintain an international good will which engineers now feel, and this may be made permanent through the International Organization of Engineers which we hope to form."

Mr. Hoover spoke of the criticisms which the people of each nation directed toward the other during normal times. "Do not take these criticisms too seriously," he said. "Some of them may have point, most of them have not; but I venture to say that in time of stress, if it ever comes again, we shall be found marching shoulder to shoulder with the same righteous end in view."

Ambrose Swasey, speaking for the members of the deputation, recited the many instances of hospitality shown its members when abroad. He said in part, "I trust that the American Section of the French Société will grow in numbers and influence. I trust that the French Sections of the American Societies will do the same, all to the end that there shall be just one great society, making for the peace of the world. We are handicapped by our ignorance of your language, but this is a small difference; while our tongues may not synchronize, our hearts are in perfect attune."

John R. Freeman, President of the American Society of Civil Engineers, pointed out to what great extent American engineers were indebted to the early French engineers for the mathematical formulas still in use, for our knowledge of hydraulic engineering, for city planning, and recently for the development of reinforced concrete construction.

J. Vipond Davies, President of the United Engineering Society, then offered the use of the Engineering Societies' Building in New York to the American Section of the Société for such purposes as it might require, and President Dumaine gratefully accepted this mark of courtesy.

Mr. Hoover, in bringing the dinner to a close, suggested that the most useful and constructive thing that could be done at this time was to bring into association men of similar callings. "In our association of engineers," he said, "there are no secrets. Their experiences, their skill and their inventions are freely interchanged and form a common bond. United they should and will form an irresistible force for the peace of the world, either by moral suasion or by making war too terrible to contemplate. Individually, or as relatively small units, we are impotent; by association only can the work be done. An international organization is not only possible, but it is practicable. We know that the French engineers have a hearty welcome here; we know that we are welcome over there, and when this new organization is formed, there will be no 'Article 10.'

The Longstreth Medal Awards

The Edward Longstreth Medal, awarded by the Franklin Institute for inventions of high order and for particularly meritorious improvements and developments in machines and mechanical processes, was presented to Joseph F. Keller of Brooklyn, N. Y., and Samuel T. Freas of Trenton, N. J., in the Hall of the Franklin Institute in Philadelphia on April 19, 1922. The Medals and accompanying Certificates are presented to "gentlemen whose inventions have been examined by the Committee on Science and the Arts and found worthy of recognition by the Institute."

The award was made to Mr. Keller for his invention of the Keller automatic die-cutting machines. These machines were described by their inventor in a paper he presented at the Annual Meeting of The American Society of Mechanical Engineers, of which he is a member, in December, 1920. The Institute believed that credit should be given to Mr. Keller for having met a recognized need for increasing die production and reproduction by methods which have resulted in easier, quicker and better production by less skillful operators and a reduction of the costs. Mr. Keller's invention which consists of a cutting tool with a tracer following a pattern, successfully overcomes the difficult problem of retaining sensitiveness with ability to do heavy cutting.

The Edward Longstreth Medal

Mr. Freas received the award for his invention of the "interlocking" tooth saw. The outstanding feature of this device is an unusual but very simple combination of wedges which holds the teeth firmly in place in spite of the intense stresses set up when doing heavy work. The excellence of his design has resulted in the extended and successful commercial use of the saw.

Presentation was made by Dr. Walton Clark, President of the Franklin Institute.

The *Majestic*, World's Largest Liner, Makes Its First Visit to New York

THE White Star liner *Majestic* docked in New York for the first time in May. Not only is she the largest liner afloat, but she will very likely continue to have this distinctive position for some time to come. The *Majestic* is the result of the prewar competition for size and speed in Transatlantic liners, and with the altered economic conditions and present high constructional costs, her equal will probably not be built for some time. Interest in the *Majestic* was doubtless increased by the fact that her sister ship, the *Leviathan*, (formerly the *Vaterland*) had recently been sent to Newport News to be refitted for Transatlantic traffic.

Originally built to the order of the Hamburg-Amerika Line at the Elbe shipyard of Blohm and Voss, Hamburg, and christened the *Bismarck*, work on her was well in hand when the outbreak of war came, and was continued till about the middle of 1916. After that time little progress was made, and about that period all copper pipes were removed and replaced by pipes of steel, which have for the most part been retained.

By the Versailles Treaty it was provided that vessels under construction should be completed by the Germans as designed and handed over to the Reparations Commission. The *Bismarck* was one of some twenty-five ships allotted to Great Britain, representing a gross tonnage of 225,000 tons. The White Star Line purchased the *Bismarck* from the Reparation Commission, and renaming her the *Majestic*, began nearly a year ago to supervise her completion.

The Majestic has an overall length of 956 ft., and is 100 ft. broad, with a gross tonnage of over 56,000 tons, and a displacement of 64,000 tons when loaded to her marks. Her height from keel to boat deck is 102 ft., and the look-out man in the crow's nest is perched 180 ft. above the water line. A special feature in the design of the *Majestic* is the arrangement of her decks. Above the five steel decks, which run from end to end of the ship, there are four steel-plated erection decks which cover at least half her length. The boiler casings, instead of passing up the centre of the vessel, are divided and placed towards the sides of the ship, and are then carried up above the top deck, where they unite to form a center superstructure for the funnels. This method, which is adopted for two of the funnels—the third being a dummy funnel—permits of better ventilation for the boiler rooms, and from an architectural point of view admits of great breadth in the disposition and size of the cabins and public rooms throughout the seven decks on which most of the first-class passenger accommodation is provided.

FIG. 1 THE WHITE STAR LINER *Majestic*

The full complement of the *Majestic* is over 5000 persons, this number including 850 first-class passengers, 545 second-class passengers, and 2392 third-class passengers, with a crew of over 1100.

The *Majestic* is driven by four-bladed propellers, each with a one-piece boss, made by the Manganese Bronze Company, Ltd., of London. Fig. 2 shows one of the spares. The propelling machinery consists of quadruple turbines of the combined-impulse and reaction type, Curtis wheels being fitted before the Parsons drums. The turbines are arranged in two engine rooms on the port and starboard. The steam enters the high-pressure turbine on the port inner shaft, and passes on to the intermediate-pressure turbine on the starboard inner shaft, from where, equally divided, it again passes to the two low-pressure turbines on the outer shafts. Each separate shaft, however, is available for running or manoeuvering by itself, but under ordinary working conditions the two low-pressure turbines operate in parallel. The total ahead horsepower is 66,000, and the astern power 36,000. According to contract, the vessel should travel at a speed of 23 knots when loaded to a mean draght corresponding to a departure draft of 35 ft. 6 in., and when the turbines are developing 66,000 shaft horsepower at a speed of 180 r.p.m., with a boiler pressure of 235 lb. per sq. in. On her run from Cuxhaven to Southampton she actually developed over 70,000 hp. and a speed of 25 knots was reached. The astern turbines are subdivided into high-pressure and low-pressure turbines, and the low-pressure turbines are again placed on the outer shafts. By-pass valves are provided whereby high-pressure steam may be supplied to the other turbines, should at any time excess steam warrant this procedure. Thrust blocks of the ordinary pattern are provided. The turbines exhaust into pear-shaped condensers, and Weir's dual air pumps are installed. The turbine controls are all worked from a special control station (Fig. 3) placed above the engine rooms, and all the main valves are hydraulically operated and electrically controlled. The boiler installation consists of 48 water-tube boilers of the Yarrow-Normand type, which are fitted with oil burners working on the White low-pressure system. The boilers, accommodated in four boiler rooms, are designed for a working pressure of 250 lb. per sq. in. The combined heating surface is over 219,000 sq. ft., and the total grate area exceeds 4000 sq. ft. The boilers are fitted throughout with Mumford's patent automatic feed controls. Aft of the main engine room is an outer engine room, containing 5 A.E.G. turbo-generating sets, each having an output of 280 kw. A large central switchboard is provided, from which the lighting and power requirements of the ship may be controlled. Current is supplied to over 15,000 electric lamps, in addition to various motors. On E deck there is a special 70-kw. emergency dynamo, driven by an A.E.G. two-stroke cycle opposed-piston type engine of the Diesel type, with two vertical cylinders, which, along with its generator, is completely enclosed. The emergency set supplies current for the lighting and wireless installations, and also provides power for the six 20-hp. motors which operate the Welin boat-handling gear.

International

FIG. 2 ONE OF THE SPARE PROPELLERS

The system of telegraphs and telephones installed throughout the ship is very complete. Among the former may be mentioned the engine telegraphs, the starting telegraphs and rudder telltale, also the docking and anchor telegraphs, the boiler-room telegraphs and the distant revolution telegraph. A loud-speaking telephone system is installed for operating the ship and for communication

between the engine and boiler rooms, and this system is so arranged that any boiler room can speak to any other boiler room or to the engine rooms and the engineers' department. Communication between the look-out man in the crow's nest and the bridge is established by a loud-speaking telephone in addition to the ordinary telephone. The ordinary telephone system for executive and departmental use has its own central exchange, which may be connected to shore when the vessel is berthed.

There are three wireless stations, and the largest is capable of maintaining permanent connection with both continents during the whole of the voyage. A smaller station is used for communication over a distance of 800 miles, and a subsidiary one is reserved for use in case of an emergency. In addition to the usual signalling arrangements, special provision has been made to guarantee as far as possible the safe navigation of the vessel in fog. Submarine signalling gear has been installed, and the Willett Bruce electric fog bell and whistle fitted. The fire-alarm system includes some 450 fire alarms, distributed throughout the ship, which automatically indicate to the officer on watch when the temperature in any compartment has been exceeded. This system is centralized on the navigation bridge, and is combined with a smoke-detection device, consisting of lines of tubing through which air may be drawn. Other signals which are shown on the navigating bridge are the water-tight door indicators and the cooling-room door telltales. Electric clocks are fitted throughout the vessel. Every precaution has been taken to reduce as far as humanly possible dangers which might arise in case of fire or collision, and an ample complement of lifeboats is carried, including two motor lifeboats fitted with wireless. All boats are swung out and lowered on the Welin system, which, as previously mentioned, is electrically operated. A somewhat novel fitting is the Fram night lifebuoy, which may be instantly released from the bridge by electrical means. Fram anti-rolling tanks are also fitted in addition to the usual bilge keels. (Description of the *Majestic* taken from *The Engineer*, vol. 133, no. 3463, May 12, 1922, pp. 522–523.)

Fig 3 Turbine Control Station

William Gleason, of Rochester, Dead

William Gleason, president and founder of the Gleason Works in Rochester, N. Y., died at his home on May 24, 1922, in his 87th year. He was born in Tipperary County, Ireland, and came to this country at the age of 15. He went to work in the machine shop of Asa R. Swift in Rochester, serving his apprenticeship there and in the shop of I. Angell & Sons. During the Civil War he was a workman in the Colt Armory in Hartford, Conn. In 1865 Mr. Gleason returned to Rochester and formed the nucleus of the Gleason Works. For a few years he was in partnership with John Connell and James S. Graham, but this partnership was dissolved in 1873. It was just at this time that he perfected the first practical bevel-gear planer which revolutionized the bevel-gear-cutting machine industry, and Mr. Gleason went with the Kidd Iron Works as superintendent. Two years later he took over the business.

Expansion of the business necessitated a larger plant in 1896. In 1910 there was a further enlargement, and the business has extended not only all over the United States but to foreign fields as well. Beginning with six employees in a one-room plant, the Gleason Works now covers more than twenty-five acres and employs 800 men. During the War the plant employed 1700 men in making ordnance supplies for the Government, and expanded its production capacity to three times its prewar capacity.

William Gleason piloted his firm through many dangerous business periods. His interest was always primarily with his employees and customers, and oftentimes he lost sight of cost and profit in an endeavor to turn out high-grade tools. He kept his standards high, and it was this integrity which brought him through periods which sometimes wrecked his competitors. At the fiftieth anniversary of the founding of the plant, old employees bore witness to his fairness and honesty.

Up until the latter part of 1920 Mr. Gleason took an active part in the management of the firm. He leaves to carry on his work two sons and Kate Gleason, his daughter, who is one of the three women members of the Society. Mr. Gleason became a member of the A.S.M.E. in 1897. He was a member of the Automobile Club of Rochester and of the Oak Hill Country Club.

Death of Henry M. Howe

Henry Marion Howe, dean of scientists in the domain of iron and steel, died on Sunday, May 14, 1922, at his home in Bedford, N. Y. Dr. Howe was born in Boston, Mass., March 2, 1848, and was the son of Dr. Samuel G. and Julia Ward Howe, both of whom were prominent in public activities. He received his A.B. from Harvard in 1869, his B.S. from the Massachusetts Institute of Technology in 1871 and his A.M. from Harvard in 1872. He received a number of honorary degrees, including an LL.D. from Harvard.

With the exception of approximately five years devoted to the metallurgy of copper, Dr. Howe's entire professional life was given up to the development of the iron and steel industry. He had an extraordinary facility in writing, and a power and tact in presiding over public meetings. Combined with an unusual keenness of observation and a devotion to the search for truth, he possessed the faculties which enabled him not only to make discoveries of his own, but to correlate and interpret the investigations of others and to clothe his data in a language so concise and simple that the ordinary mind could comprehend. The results of his labors are accessible to all in a number of books, several of which have been translated into French and Russian, and in many articles in encyclopedias and technical journals. His works give him the rank of the world's greatest authority on the metallurgy of steel.

Dr. Howe was famous as an expert in litigation on iron and steel. At the time of his death he was professor emeritus at Columbia University, where he had been professor of metallurgy from 1897 to 1913. During the World War and for some years subsequently, he served as Chairman of the Engineering Division of the National Research Council. He was a Past-President of the American Institute of Mining and Metallurgical Engineers, the American Society for Testing Materials, the International Association for Testing Materials, the Jury of Awards, Mining and Metallurgy, Chicago Exposition, etc.

In January of 1917 Dr. Howe was awarded the John Fritz Medal for his "investigations in metallurgy, especially in the metallography of iron and steel." Dr. Howe was the thirteenth to receive this signal honor since its first award in 1902 to John Fritz. The Medal is awarded for notable scientific or industrial achievement by a Board of Sixteen appointed in equal numbers from the members of the four national societies; American Society of Civil Engineers, American Institute of Mining and Metallurgical Engineers, American Society of Mechanical Engineers and the American Institute of Electrical Engineers.

Honors had been conferred upon him by scientific societies not only of our own country but of many of the steel-producing nations of the world. He was an honorary member of the American Iron and Steel Institute and had received the Bessemer Medal of the Iron and Steel Institute of Great Britain.

Engineering and Industrial Standardization

Standards in the Making

Gears. Reprints of the five standards published in the May issue of MECHANICAL ENGINEERING were presented to the American Gear Manufacturers' Association during its recent meeting in Buffalo. The Society of Automotive Engineers and the American Society for Testing Materials have also distributed copies of these reprints to their interested committees. The Sectional Committee on Gears is now awaiting comments. *Chairman*, B. F. Waterman; *Secretary*, J. P. Kotteamp.

Shafting. With the standards for transmission and machinery shafting diameters and their tolerances out of the way, this Sectional Committee is now turning its attention to key sizes and tolerance and also to the development of a standard method for determining the size of shaft necessary to transmit a given load.

The Sub-Committee which is working on this latter problem has completed the first third of its work which covers the various stress conditions that may be set up in a transmission shaft; the various theories, evolved from time to time, leading to the many formulas found in engineering literature; the application and limitation of the various theories of elastic failure as applied to ductile ferrous material used in shafts. *Chairman*, C. M. Chapman; *Secretary*, C. B. LePage.

Machine-Screw Threads. The Sectional Committee on the Standardization and Unification of Screw Threads is now reviewing the revised report of its Working Committee. An open meeting will be held in the near future at which this report will be passed on finally and the report of the Sub-Committee on Gages and Gaging Methods will be presented for discussion. *Chairman*, L. D. Burlingame; *Secretary*, C. B. LePage.

Ball Bearings. Following the return of Mr. O. R. Wikander from his visit to France and Germany where he conferred with standards authorities of these countries, and also those of Sweden, a series of meetings of the Sectional Committee was held in New York. At these meetings counter proposals to those made by the Germans and the Swedes were drafted and sent abroad. These proposals concern the standards for the widths and depths of radial bearings.

A Sub-Committee of the Ball and Roller Bearings Division of the Society of Automotive Engineers, one of the sponsor bodies, is at work on the standardization of thrust bearings. It is working on the O. D., I. D. and distance between faces of single- and double-direction flat-face and self-aligning bearings. *Chairman*, W. R. Strickland; *Secretary*, R. S. Burnett.

Pipe Flanges and Fittings. This large Sectional Committee is making excellent progress in the work assigned to it. Sub-Committee No. 3 has completed a set of dimensions for standard malleable cast-iron and non-ferrous screwed fittings from 1/8 inch to 6 inches. This report has passed the Sub-Committee and has been approved by the Sectional Committee. It will therefore appear in an early issue of MECHANICAL ENGINEERING.

Sub-Committee No. 1 is now considering the preliminary draft of its report on the revisions to the 125-lb. and 250-lb. flange standards issued by the Joint Committee in 1914.

Sub-Committee No. 2 has so far confined its activities to collecting information on the work which has already been done throughout the country in the design of flange joints for pressures above 250 lb. *Chairman*, C. P. Bliss; *Secretary*, A. C. Taylor.

Plain Limit Gages for General Engineering Work. The February 1921 issue of MECHANICAL ENGINEERING contained a questionnaire on the subject of Machine Fits which had been prepared by this Sectional Committee. This questionnaire was reprinted and 1000 copies distributed by mail to as many manufacturers and users of plain limit gages. The replies to the twenty-one questions it contained have been carefully studied by a Sub-Committee, which has just completed a 66-page report for the consideration of the Sectional Committee. Copies of this report are now in the hands of the members of the full Committee and a meeting is to be called during June. *Chairman*, E. C. Peck; *Secretary*, H. W. Bearce.

Bolt, Nut and Rivet Proportions. As previously reported this Sectional Committee was organized on March 16. The seven Sub-Committees which were appointed on that day have since been steadily at work securing information on present practice. These Sub-Committees are planning to prepare standards for (1) Large and Small Rivets, (2) Wrench-Head Bolts and Nuts, (3) Slotted Heads, (4) Track Bolts, (5) Carriage Bolts, (6) Special Bolts and Nuts for Agricultural Machinery, and (7) Body Dimensions and Material.

Small Tools and Machine-Tool Elements. The personnel of the Plan and Scope Committee mentioned in this page of the June issue has now been completed and the Committee is at work. Though it has so far issued no official report, it is probable that the first two projects which the Sectional Committee will be asked to undertake are (1) the reduction in the number of sizes of all the various kinds of machine tools and (2) the standardization of the tee (T) slots employed in these types of machines. The first of these will be accomplished most likely by the adoption of the "Preferred Number" method of determining standard sizes, while the second will of necessity be a compromise between the many sizes and proportions shown by the large amount of data already collected.

Color Schemes for Systems of Piping. This Sectional Committee has just been organized under the sponsorship of the National Safety Council and The American Society of Mechanical Engineers. A considerable amount of data on this subject has, however, been collected by the Sponsors during the past two years, so that the early issuance of a preliminary report may be expected.

Roller Transmission Chains. A series of four closely related standards has thus far been developed by this Joint Committee and published by the S.A.E. and the A.S.M.E. These standards cover (*a*) Roller Chain Dimensions including a System of Numbering, (*b*) Sprockets and their Tooth Form, (*c*) Minimum Breaking Strength for Standard Chains, and (*d*) Standard Nomenclature for Roller Chain-Components.

In connection with the work on the Roller-Chain Sprocket Cutters a slight change in the sprocket-tooth form has been suggested by a member of the Committee which, if adopted, will greatly simplify the present method of laying out the sprocket teeth. As a result of this suggestion the Committee is reconsidering its previous report.

The Sub-Committee which is making a preliminary study of the three remaining subjects, i.e., (*e*) Maximum Working Loads for Standard Chains, (*f*) Maximum Revolutions per minute for Sprockets and (*g*) Maximum Chain Velocities for Different Number of Teeth, states through its Chairman, Mr. G. M. Bartlett, that more research work at the plants of the manufacturers will be necessary before his Sub-Committee can submit a report to the Joint Committee.

Two Standard Specifications before the A.E.S.C. for Approval

Raw and Boiled Linseed Oil. Specifications for Purity of Raw Linseed Oil from North American Seed (D1–15) and for Purity of Boiled Linseed Oil from North American Seed (D11–15) were prepared by American Society for Testing Materials Committee D-1 on Preservative Coatings for Structural Materials. The development of these specifications was begun in 1908. Samples of linseed oil of known purity were obtained and specifications for analysis prepared; portions of these samples were distributed among competent chemists and the results of their examinations reported. Based upon these results, the specifications prepared were submitted to all the manufacturers of linseed oil in the United States with the request that the manufacturers comment upon their acceptability. The consensus of opinion was that work should be done on the examination of linseed oil from different crops of seed before adopting specifications. Additional work was carried on in the several years following, and in 1915 the revised specifications were adopted. Both standards have stood without revision since their adoption, although the committee is continuing to work to improve the specifications by additional methods of test.

Laboratory Methods of Sampling and Analysis of Coke. These methods were formulated by Committee D-6 of the American Society for Testing Materials in coöperation with the American

Chemical Society, the American Foundrymen's Association and the U. S. Bureau of Mines. The specifications are such that methods of coke analysis conform in as far as practicable, with methods of coal analysis, making due allowance for the difference in procedure desirable in the analysis for coke.

These two process standards are submitted by the American Society for Testing Materials to the American Engineering Standards Committee in accordance with the special procedure of the Committee, under which important standards in existence prior to 1920 may be approved without going through the regular process followed in new work.

The A.E.S.C. would be very glad to learn from those interested of the extent to which they make use of these specifications and to receive any other information regarding the specifications in meeting the needs of the industry.

Progress of Standardization in Belgium

Great strides toward standardization, particularly in the construction, metals, mining, and electrical industries of Belgium, are indicated in a report from the Association Belge de Standardization which has just been received by the American Engineering Standards Committee.

The report shows that the following standards have been approved for issue in Belgium: Rules for the Construction of Steel Roof Trusses, Rules for the Construction of Steel Tanks, Rules for the Construction of Galvanized Corrugated Roofs and Partitions, Standardization of Steel Bridges, Tentative List of Equal Angles, Standardization of Shafts and Pulleys, Standardization of Bolts and Rivets, Standard Requirements for Electrical Machinery, Electrotechnical Vocabulary.

These standards, with the exception of the Tentative List of Equal Angles, have been printed and copies are now available through the American Engineering Standards Committee. The Tentative List of Equal Angles is up for printing.

The report shows also that the following proposed standards have been published in the press of Belgium for criticism: Rules for the Design and Inspection of Reinforced-Concrete Structures, Chains (Dimensions of links; material; reception tests), Wire Cables for Cranes, Hoists, Elevators and Mining Purposes.

The Draft Specification for Methods of Analysis for Zinc Ores, Spelter, etc. is under consideration. It is also shown in the report that work on the following proposed standards is in the hands of Technical Committee: Cast-Iron Pipes and Fittings for Water Works, Rules for the Design of Shafting, Standardization of Tolerances, Dimensions of Paper, Drawing, etc.

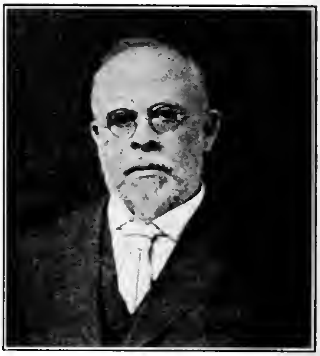
On the subject of Flanges for Steel Tubes and on Chains (Dimensions of rings and hooks) decisions have been made to undertake standardization.

Copies of pending standards will also be available through the American Engineering Standards Committee, 29 West 39th St., New York, as soon as published.

The Specifications and Tests for Portland Cement, for which the American Society for Testing Materials is sponsor, have been advanced to the full status of "American Standard" by the American Engineering Standards Committee. These specifications, which have been developed as a result of the experience of the industry through several years, were first approved by the A.E.S.C. as Tentative American Standard in 1919. They were reapproved in 1921 after agreements had been reached which eliminated slight differences between the Government and the commercial specifications, resulting in nationally recognized uniform specifications.

There are seven forms of nailed wooden boxes so universally used that they may be called the standard styles of nailed boxes. These boxes can be adapted to a wide range of uses, and it is the experience of the Forest Products Laboratory, Madison, Wis., that in meeting the majority of packing problems they are the most efficient of the nailed boxes. The advantages and disadvantages of each style, as revealed in laboratory tests and observations of boxes in commercial service, are given in a pamphlet recently issued by the Laboratory under the designation, Technical Note No. 164.

A. W. Gibbs, Chief Mechanical Engineer of the Pennsylvania System, Dies



Alfred Wolcott Gibbs

Alfred Wolcott Gibbs, chief mechanical engineer of the Pennsylvania Railroad System, died on May 19, 1922. Mr. Gibbs was born at Fort Filmore, N. M., on October 27, 1856. He received his preparatory schooling at Rutgers College Grammar School and then studied for two years in Rutgers College, when he entered Stevens Institute of Technology, being graduated in 1878.

In March, 1879 Mr. Gibbs entered the service of the Pennsylvania Railroad Co. as a special apprentice at the Altoona Shops, continuing such service until June 1, 1881, when he became draftsman with the Richmond and Danville Railway. In 1886 he was appointed master mechanic of the Atlantic and Charlotte Division of that line and two years later became superintendent of motive power of the Central of Georgia Railway. When that position was abolished he was again appointed master mechanic on the Atlantic and Charlotte Division.

In 1893 Mr. Gibbs reëntered the service of the Pennsylvania Railroad Co. as assistant mechanical engineer and nine years later was advanced to the position of superintendent of motive power of the Philadelphia, Wilmington & Baltimore Railroad Co. On January 1, 1913, Mr. Gibbs was appointed general superintendent of motive power of the Pennsylvania Railroad Co. In 1911 he assumed the duties of the newly created position of chief mechanical engineer of that line and under the reorganization in 1920 became chief mechanical engineer of the Pennsylvania System.

Mr. Gibbs became a member of The American Society of Mechanical Engineers in 1920. He was also a member of the Mechanical Division of the American Railway Association, of the American Engineering Standards Committee, the American Railway Engineering Association, the American Society of Naval Engineers, of the Board of Managers of the Franklin Institute, of the Board of Managers of the Philadelphia Institute and Free Library and Past-President of the American Society for Testing Materials.

Arthur J. Wood Appointed to Succeed Professor Fessenden at Pennsylvania State College

Arthur J. Wood, professor of railway mechanical engineering at Pennsylvania State College, has been appointed head of the department of mechanical engineering to succeed Professor E. A. Fessenden. Professor Fessenden goes to Rensselaer Polytechnic Institute in the fall.

Professor Wood was graduated in 1896 from Stevens Institute of Technology. He was associate editor of the *Railroad Gazette*, and preceding his appointment to the State College faculty he was an instructor in mechanical engineering at Worcester Polytechnic Institute and professor of mechanical and electrical engineering at Delaware College. He went to Pennsylvania State College as assistent Professor of Experimental Engineering in 1904 and was made associate professor of railway mechanical engineering in 1909.

Recently he has been in direct charge of the Engineering Experiment Station at State College, where he became greatly interested in problems of heat transmission. He has derived a method for testing insulation and in coöperation with a number of other experiment stations has carried on extensive insulation tests. He has developed the course in railway mechanical engineering and has written a textbook on locomotive operation. He is the chairman of the Central Pennsylvania Section of The American Society of Mechanical Engineers. He has been a member of The American Society of Mechanical Engineers since 1907.

NEWS OF OTHER SOCIETIES

American Water Works Association

In a convention notable for close adherence to program, the American Water Works Association met in Philadelphia at the Bellevue-Stratford Hotel the week of May 15, 1922. Fifty papers and committee reports, not including the topical discussions on Superintendent's Day, were presented. With the exception of Wednesday afternoon, which was the occasion of a boat ride on the Delaware, the entire time of the convention was devoted to papers and discussions.

In his presidential address, Dr. Edward Bartow stressed the duties of the water-works superintendent, particularly his relations with the public. Leonard Metcalf, member of the A.S.M.E., presented a valuable paper on the Improved Financial Condition of Water Works. Filtration, chlorination, tastes and odors, the effects of waste matters, and water softening were a few of the topics touched upon in other papers. Eight sub-committee reports on the work of the Council on Standardization were among the most valuable features of the week. The meetings of the Chemical and Biological Section were crowded throughout, and Superintendents' Day was an unusually successful undertaking.

Robert Morse, chairman of the Publication Committee, gave in his report a classification of the membership in groups such as executives, superintendents, engineers, chemists, etc. Of the entire membership, 43 per cent were classified as engineers.

An unusually attractive display of the Water-Works Manufacturers' Association featured the convention. It was voted to hold the meeting next year in Detroit. There was no opposition to the report of the Nominating Committee and the following officers were elected: President, W. S. Cramer; Vice-President, George W. Fuller; Treasurer, W. W. Brush; and Trustees, George W. Batchelder and J. W. Ellms.

National Electric Light Association

The forty-fifth convention of the National Electric Light Association, held in Atlantic City May 15–17, brought together delegates and guests from every corner of the United States to attend sessions that marked exceptional progress in the industry. The Association is undoubtedly in more intimate contact with its problems than ever before, and the convention this year points to continued solid progress. The industry is unanimously back of the better business movement and "Electrify America" is a slogan fast becoming a fact.

One of the high spots of the week was the dramatic demonstration by the American Telephone & Telegraph Company which made possible a half-hour of simultaneous meeting with the Pacific Coast association. The place of honor on the crowded program was given for the first time in the history of the organization to a symposium on business development, presented by Henry L. Doherty, Guy E. Tripp, W. E. Robertson, W. W. Freeman, Farquson Johnson and H. A. Lane.

It was necessary to hold a number of parallel sessions during the week. In addition to the general sessions there were technical, commercial, accountants, and public-relations sessions.

The feature of the meeting of most importance to mechanical engineers was the presentation of the Prime Movers Report which had been prepared under the direction of H P. Liversidge, Chairman of the Committee on Prime Movers. This document comprises 340 pages and provides much valuable information showing progress in central-station development. Due to the delay in printing the report, the discussion was limited to a record it included which showed idle time of a number of large generating units.

O. F. Jungren of the General Electric Company and F. Hodgkinson of the Western Electric and Manufacturing Company discussed the respective merits of single- and double-drum turbines. I. E. Moultrop, of the Edison Electric Illuminating Company, stated his opinion that turbine reliability was of much greater importance than efficiency.

John Anderson of the Milwaukee Electric Railway and Light Company presented some of the facts regarding the installation of pulverized fuel in the Lakeside Plant, which, after fourteen months of operation, has generated 200,000,000 kw-hr. without interruption due to prime mover or generating equipment. This station was designed for a thermal efficiency of 19.2 per cent and a boiler and economizer efficiency of 88 per cent. Mr. Anderson was confident that these efficiencies could be obtained under normal operating conditions with the complete installation. Nevertheless, using coal averaging from 9000 to 13,500 B.t.u. per lb. and with a night load only 30 per cent of the day load, an average station water rate of 12.7 lb. per kw-hr. has been obtained. Boiler efficiencies during steaming period have varied from 84.2 to 85.9 during the past six months. The overall boiler-room efficiency varied from 83.2 to 84.18 during the same period, and 19,097 B.t.u. per kw-hr. (net) or a thermal efficiency of 17.88 has been achieved. Mr. Anderson stated that preheating the air to the furnace will not entirely eliminate feeding trouble, and that coal to feed regularly must have less than 8 per cent moisture. To remove ash in the smoke a washer was installed in the underground breeching in a ten-day test. This washer, which consists of a curtain of water, caught 70 per cent of the ash.

At the concluding general and executive session the following officers were elected: President, Frank W. Smith; vice-presidents, Walter H. Johnson, Franklin T. Griffith, J. E. Davidson and R. F. Pack; Treasurer, Walter Neumuller.

American Boiler Manufacturers' Association

The thirty-fourth Annual Convention of the American Boiler Manufacturers' Association was held at Shawnee-on-Delaware, Pa., June 5, 6 and 7. President A. G. Pratt of the Babcock & Wilcox Co. opened the meeting with an address dealing with the attitude of the Federal administration toward the trade association and favoring coöperation along methods outlined at the conference of trade associations called by Secretary Hoover.

Dr. M. W. Alexander, managing director of the National Industrial Conference Board, described the methods and purposes of the Board and showed some of the results of its analyses and studies on the labor supply, the rise and fall of wages as compared with the cost of living, etc.

In the evening E. C. Fisher of the Wickes Boiler Co. presented a paper on A Study of Thickness of Shell Plates in Return-Tubular Boilers and R. Sanford Riley, president of the Sanford Riley Stoker Co., exhibited films of a stoker fire in operation.

On Tuesday morning E. R. Fish, who represents the Association on the Boiler Code Committee of the A.S.M.E., told of the work of that Committee, and Chas. E. Gorton, chairman of the Uniform Boiler Law Society, reported the progress of boiler legislation in several states. J. F. Scott, chairman, and C. O. Myers, secretary-treasurer of the National Board of Boiler and Pressure-Vessel Inspectors, gave reports on the progress of that organization. Reports were also presented by the Conference Committee with the Stoker Manufacturers' Association, the Committee on Ethics and the Committee Appointed to Investigate the Proper Setting Heights of Hand-Fired Return-Tubular Boilers.

The last named Committee recommended that a committee be named to confer with a similar committee to be appointed by the Affiliated Smoke Prevention Bureaus, meeting in Cleveland in the near future, with the view of taking coöperative action to standardize setting heights in the various districts that would meet with the approval of the boiler manufacturers and the legal authorities having the matter in charge.

On Wednesday morning the meeting was addressed by Charles Aubrey Eaton of the American Educational Association on the broad effects of education on citizenship and political, industrial and social relations, the satisfactory adjustment of which depends upon the creation of right thinking and intelligence rather than the accumulation of undigested knowledge.

C. S. Blake, president of the Hartford Steam Boiler Inspection and Insurance Co. and chairman of the sub-committee of the A.S.M.E. Boiler Code Committee, presented for discussion and advisement the tentative code on Inspection of Steam Boilers now being formulated.

The Buckwood Inn at which the convention was held afforded unusual opportunities for entertainment between sessions, not the least of these being the nationally known golf course on which several tournaments were held. At the banquet on Tuesday evening C. V. Kellogg acted as toastmaster.

LIBRARY NOTES AND BOOK REVIEWS

A Dictionary of Applied Physics

A Dictionary of Applied Physics. Edited by Sir Richard Glazebrook. Vol. 1. Macmillan and Co., Ltd., London, 1922. Cloth, 6×9 in., 1067 pp., illus., diagrams, $15.

During the past twenty-five years the applications of physics to industry have grown enormously. Governments, universities and manufacturers have undertaken research upon a large scale and a vast amount of information of practical usefulness has accumulated.

The development of the science has paralleled that in the sister science, chemistry, with one important difference. While the chemist has from time to time published cyclopedias and dictionaries from which he could quickly ascertain the salient facts concerning any subject, the results of the labors of physicists have remained scattered in the proceedings of learned societies or stored in the brains of the workers themselves. The engineer or manufacturer interested in getting the latest and most accurate information upon the subject with which he was concerned, faced a long search in libraries and a tedious inquiry for experts.

The Dictionary of Applied Physics is the first serious attempt to remedy this condition. It will appear in five volumes of 800 to 1000 pages, and will contain modern information on the wide range of subjects included within its title. The editorial direction has been placed in the competent hands of Sir Richard Glazebrook, and the assistance of the most competent physicists of Great Britain has been obtained.

In order that it may not be necessary for the individual to purchase all the volumes, the work is arranged so that all of any subject is contained in a single volume. Within each volume, the arrangement is alphabetical. The first volume covers Mechanics, Engineering and Heat, and is of particular interest, therefore, to mechanical engineers.

The following list of the contributors and subjects of the important articles indicates the scope and authoritativeness of the first volume: George S. Baker, Ship Resistance and Propulsion; Reginald A. Batson, Determination of Elastic Constants and the Testing of Materials of Construction; Dr. G. T. Bennett, Gyroscope; Charles H. Beeleid, Kinematics of Machinery; Andrew Cruickshank, Reciprocating Steam Engine; William E. Dalby, Balancing of Engines and Prime Movers; Robert Dawson, Development of the Steam Turbine; Aubrey T. Evans, Water-Cooled Petrol Engine; Dr. Angus R. Fulton, Hydraulics; James H. Hyde, Dynamometers, and Mechanical Powers; Dr. Horace Lamb, Fourier's Series, Simple Harmonic Motion, Stream-Line Motion, and the Mathematical Theory of Conduction of Heat; J. W. Landon, Strength of Structures; Dr. Hyman Levy, Principles of Dynamical Similarity; Research Staff of the General Electric Company, Air Pumps; R. V. Southwell, Theory of Elasticity; Dr. T. E. Stanton, Friction; W. J. A. Butterfield, Fuel Calorimetry; Sir Dugald Clerk, Thermodynamics of Internal-Combustion Engines, and Some Typical Internal-Combustion Engines; Dr. Arthur L. Day, Realization of the Absolute Scale of Temperature; Sir J. A. Ewing, Liquefaction of Gases, Refrigeration, Theory of the Steam Engine, and Thermodynamics; Dr. Ernest H. Griffiths, Mechanical Equivalent of Heat; Dr. Ezer Griffiths, Bomb Calorimeters, Calorimetry; Latent Heat Pyrometry, Resistance Thermometers, and Thermocouples; William B. Hardy, Boundary Conditions in Lubrication; Dr. John L. Haughton, Thermostats; William F. Higgins, Flash-Point Determination, Thermometry, and Viscometry; Alfred W. Porter, Thermal Expansion; David R. Pye, Specific Heat of Gases; F. H. Schofield, Conduction of Heat, and Convection of Heat.

Bibliographies are frequently given and an index to authorities cited is added to the volume. The articles are sufficiently long to be satisfactory summaries of present knowledge. The work, judging by the first volume, will be an invaluable work of reference to every one who is interested in the field of engineering research.

Harrison W. Craver.

Metal Cutting Tools

Metal Cutting Tools. By A. L. DeLeeuw. First edition. McGraw-Hill Book Co., New York, 1922. Cloth, 6×9¼ in., 328 pp., 306 figs., price $3.50.

Mr. DeLeeuw's book as compared, for example, with the classical work of Fred W. Taylor on The Art of Cutting Metals, belongs to a distinctly new era.

Some 25 years ago tools were primarily built for general purpose work. There were a few specialized shops using quantity production on what was supposed to be single-purpose tools, such as sewing machines and typewriters, but the number of these shops was very small and the tools which they employed were really crude adaptations of standard tools to the particular tasks performed.

In the last quarter of a century, primarily under the leadership of the automobile industry, a profound change has taken place. Single-purpose tools, sometimes of considerable size and not unusually of quite complicated construction, have been developed to supply the millions of parts on repetition work that modern standardized industry demands.

When a tool has to perform one function or one set of functions day in and day out, possibly in a number of plants, it becomes worth while to devote a good deal of attention and research to the particular performance of that tool, because even a slight saving in the cost of production per part made, would amply repay for the time and labor spent. We see therefore the appearance of extensive and highly organized investigations on the performance of various machine tools, of which a good example may be seen in the recent paper by Professor Coker before the Institution of Mechanical Engineers.

The book on Metal Cutting Tools by A. L. DeLeeuw represents an interesting attempt to give a synopsis of our knowledge of the facts underlying the performance of the various classes of tools and to discuss various tools in the light of these underlying facts. From this point of view Chapter 1 is perhaps of the greatest interest, as it explains the fundamental conditions affecting the action of a cutting tool and thus provides the basis for understanding the general principles of design of metal-cutting tools.

The book covers the various types of planer tools, boring tools, milling cutters, form and shear tools, generating tools, thread-cutting tools and hollow mills. In discussing every one of these types of tools the author starts with an analysis of the conditions underlying operation and from that builds up first the ideal conception of what a tool of that particular class should be, proceeding from this to a description, and at times criticism, of the particular tools now available.

The book is written in remarkably simple language and (which is by no means as usual as it should be) is not encumbered by unnecessary mathematics and antiquated tables of experimental data.

L. Cammen.

Book Notes

Annals of the American Academy of Political and Social Science. May, 1922. Paper, 6×9 in., 315 pp., $1.

The American Academy of Political and Social Science has done a great service to all the professions by bringing together for the first time in one collection the concepts of what constitutes the attainment of the ideals of a profession, in distinction from those of a vocation. As respects the Engineering Societies, the authors representing the leading societies have, by long contact in their respective organizations, not only themselves advanced the high ideals of their professions but have contributed personally, both in conference and in committee, to the adoption of those principles which they describe in their several articles. Every engineer wishing to stand for the advancement of his profession should read this entire issue of The Annals.

Cours de Mecanique Appliquee. By Marcel Lamotte. Gauthier-Villars et Cie, Paris, 1922. Paper, 6×10 in., 282 pp., diagrams, 25 fr.

Professor Lamotte feels that most textbooks of applied mechanics require more extensive knowledge than the usual student possesses and are unnecessarily difficult He has prepared this book, not to replace the more elaborate treatises on the subject, but to prepare the student for them, so that he may derive the most profit from their perusal. This is accomplished by presenting, in the simplest form possible, some of the questions that affect the applications of mechanics. He is less concerned in establishing general theories than in showing, by examples, how practical problems may be solved.

Cyaniding Gold and Silver Ores. By H. Forbes Julian and Edgar Smart. Third edition, revised and enlarged J. B. Lippincott Co., Philadelphia, 1921 Cloth, 6×9 in., 417 pp., diagrams, tables, $12.50

The second edition of this well-known treatise appeared in 1907. Work upon the present edition began in 1914, was interrupted by the death of Mr. Smart and by the Great War, but was finally completed by A. W. Allen. Much new material dealing with recent modifications in the theory and operation has been added and the chapters have been rearranged to secure greater uniformity. The principal additions are in connection with colloidity and absorption; the theory of gold precipitation on charcoal; milling in cyanide solution, flotation and cyanidation; zinc-box practice; deoxidizing solutions, counter-current decantation; aluminium, sodium sulfide and charcoal precipitation; agitation, slime-settlement and filtration equipment.

Fuel and Refractory Materials. By A. Humboldt Sexton. New edition, revised by W. B. Davidson. D. Van Nostrand Co., New York, 1921. Cloth, 6×9 in., 382 pp., illus., diagrams, tables, $4.

No important alterations have been made in the original text of this well-known work, but minor corrections have been made throughout. The chapters on liquid and gaseous fuels have been modified and enlarged, and the chapter on by-products has been rewritten. The chapters on fuel testing and refractories have been modernized and enlarged. The book discusses the important industrial fuels, metallurgical furnaces, pyrometry, calorimetry, fuel testing and the refractory materials used for furnaces and crucibles.

Lapping and Polishing. By Edward K. Hammond. First edition. Industrial Press, New York, 1921. (*Machinery's* blue books.) Paper, 6×8 in., 60 pp., illus., $0.50.

This pamphlet reviews modern practice in lapping operations, in the light of the improvements developed during recent years, and also gives an account of current methods for polishing tools and parts.

Manual of Flotation Processes. By Arthur F. Taggart. John Wiley & Sons, Inc., New York, 1921. Cloth, 6×9 in., 181 pp., diagrams, $3.

Widespread understanding of the physical principles underlying flotation phenomena and of the diversity of flotation processes has been delayed, partly by the apparent complexity of the phenomena and the difficulties of investigation, in part by the attitude of corporations owning patents on flotation processes. It is the purpose of this book, in part, to counteract the further spread of false conceptions, by setting forth some of the facts that contradict them, in part to describe apparatus and methods of testing which will aid investigators in their researches; and finally to give some generalizations from mill practice, by means of which the investigator may translate laboratory results into commercial operations.

Manufacture of Pulp and Paper. Vol. 3. First edition. McGraw-Hill Book Co., Inc., New York, 1922. Cloth, 6×9 in., illus., diagrams, $5.

This is the third volume of the course of instruction in pulp and paper manufacture prepared by the pulp and paper industry of North America for those actively engaged in the industry. Previous volumes have been devoted to the elementary scientific knowledge—physical, chemical and mathematical—needed by the paper maker; the present volume takes up the actual manufacturing processes. It is, the editor announces, the first work in English dealing solely and comprehensively with wood-pulp manufacture. The various sections have been prepared by specialists. They describe the properties of pulpwood, its preparation, the manufacture of mechanical, sulphite, soda and sulphate pulps, and the treatment, refining, testing and bleaching of pulp.

Metric System for Engineers. By Charles B. Clapham. Dutton & Co., New York, 1922. (Directly useful technical series.) Cloth, 6×9 in., 181 pp., $6.

This book is not concerned with the controversy regarding the metric system. Its object is to give a full, practical explanation of the system as it is met in engineering calculation and measurement, for use by draftsmen, mechanics and engineers. After an introduction explaining basic principles, the simple measures of length, area, volume, capacity and weight are discussed, with special attention to the usual measuring tools found in workshops and drafting rooms. Compound measures used in engineering are then described, with the derivation of the corresponding British equivalents. Succeeding chapters give tables of the commoner engineering constants in British and metric units, and examples of the alteration of numerical constants in formulas when metric values are to be used.

Motor Truck Transportation. By F. Van Z. Lane. D. Van Nostrand Co., New York, 1921. Cloth, 6×9 in., 153 pp., illus., $2.

A practical presentation of the principles of truck-operating cost; operating efficiency and cost records; operating cost laws; truck details, such as bodies, loading and unloading devices, trailers and semi-trailers, and tires; and the factors that determine the fields of economical operation. Gives no attention to design or manufacture.

Physique Elementaire et Theories Modernes. By J. Villey. Part 1. Molecules and atoms. Gauthier-Villars & Co., Paris, 1921. Paper, 6×10 in., 197 pp., 15 francs.

The author has prepared a work, less scholastic than usual textbooks and more suited for reading, in which the essential phenomena of physics are set forth and explained by the most modern theories. Attention is especially directed to those phenomena which have received industrial application. The work is intended for the general public desirous of information about the fundamentals of physics and modern theories, as well as for use as a text book.

Protective Relays. By Victor H. Todd. First edition. McGraw-Hill Book Co., Inc., New York, 1922. Cloth, 6×8 in., 274 pp., illus., diagrams, $2.50.

This book attempts to cover the subject from first principles to the protection of high-tension networks, in a manner suited to the needs of operators and testers with a fair knowledge of electricity, and also of designers.

Sewerage and Sewage Disposal. By Leonard Metcalf and H. P. Eddy. First edition. McGraw-Hill Book Co., Inc., New York, 1922. Cloth, 6×9 in., 598 pp., illus., diagrams, $5.

This work is practically a one-volume abridgment of the three-volume treatise American Sewerage Practice published by these authors in 1914–1915. It is intended for class use in engineering schools, but reflects the viewpoint of the engineer, not the teacher, and presents the information that its authors believe young students should acquire before taking up work in the field of sewerage engineering.

Short Course in the Testing of Electrical Machinery. By J. H. Morecroft and F. W. Hehre. Fourth edition, revised and enlarged. Van Nostrand Co., New York, 1921. Cloth, 6×9 in., 220 pp., diagrams, $3.

All students of engineering at Columbia University are required to take courses in testing direct and alternating-current machinery. These notes are prepared to meet the needs of students in mining, mechanical and civil engineering, who have not studied the theory of electrical machinery, and hence need a brief summary of it as preparation for the laboratory work. Besides giving specific directions for the tests, a brief analysis of the characteristics of the machines is given. The new edition includes new material on batteries, illumination, measurement of electrical energy and other subjects of interest to engineers generally.

THE ENGINEERING INDEX

(Registered United States, Great Britain and Canada.)

THE ENGINEERING INDEX presents each month, in conveniently classified form, items descriptive of the articles appearing in the current issues of the world's engineering and scientific press of particular interest to mechanical engineers. At the end of the year the monthly installments are combined along with items dealing with civil, electrical, mining and other branches of engineering, and published in book form, this annual volume having regularly appeared since 1906. In the preparation of the Index by the engineering staff of The American Society of Mechanical Engineers some 1200 technical publications received by the Engineering Societies Library (New York) are regularly reviewed, thus bringing the great resources of that library to the entire engineering profession.

Photoprint copies (white printing on a black background) of any of the articles listed in the Index may be obtained at a price of 25 cents a page. When ordering photoprints identify the article by quoting from the Index item: (1) Title of article; (2) Name of periodical in which it appeared; (3) Volume, number, and date of publication of periodical; (4) Page numbers. A remittance of 25 cents a page should accompany the order. Orders should be sent to the Engineering Societies Library, 29 West 39th Street, New York.

ACETYLENE

High-Pressure Apparatus. High-Pressure Acetylene Apparatus (Hochdruck-Acetylenapparat), K. Matzinger. Autogene Metallbearbeitung, vol. 15, no. 6, Mar. 15, 1922, pp. 80–82, 4 figs Describes apparatus used for Schoop's metal-spraying process built by Continental Light & Apparatus Construction Co. in Zurich-Dübendorf.

AERIAL PHOTOGRAPHY

Cameras. Practical Uses of Aerial Photography. Aviation, vol. 12, no. 15, Apr. 10, 1922, pp. 424–426, 5 figs. Describes Fairchild camera used for producing aerial map of New York City.

AERONAUTICAL INSTRUMENTS

Air-Speed Recorder. Manometer For Recording Air Speed, C. Wieselberger. Aerial Age, vol. 15, no. 6, Apr. 17, 1922, pp. 131–132, 3 figs. Describes instrument made at Göttingen aerodynamic laboratory, answering following conditions: (1) Must respond quickly so that all speed variations will be correctly recorded. (2) Must not be affected by rectilinear or curvilinear accelerations. Hence, movable parts must be counterbalanced. Translated from Zeit. für Flugtechnik u. Motorluftschiffahrt.

Electrical. Electrical Instrument Equipment for Aircraft, Edgar A. Griffiths. Beama, vol. 10, no. 4, Apr. 1922, pp. 299–307, 16 figs. Characteristics of engine revolution indicator, oil pressure transmitter, thermometric instruments, rate of climb meter, gyroscopic devices, and transmitting compass.

AERONAUTICS

Seaplane Coefficients. Full Scale Seaplane Coefficients, Max M. Munk. Aviation, vol. 12, no. 17, Apr. 24, 1922, pp. 482–483, 1 fig. Lift and drag coefficients of Brandenburg seaplane determined in free-flight tests.

AIRCRAFT

Research. The Progress of Research, R. K. Bagnall-Wild. Aerial Age, vol. 15, nos. 4 and 5, Apr. 3 and 10, 1922, pp. 78–79 and 103–104. Aero engine research; navigation; machines; materials. See also Flight, vol. 14, no. 8, Feb. 23, 1922, pp. 122–124.

AIRCRAFT CONSTRUCTION MATERIALS

Brazing. Investigation of Dip Brazing with High Melting Point Brass. Air Service Information Circular, vol. 3, no. 297, Feb. 15, 1922. Continuation of investigation recorded in A.S.I.C. vol. 3, no. 203. Determination of best flux and heat treatments for brass of this type.

AIR COMPRESSORS

New Efficient Type. A New Air Compressor. Oil Eng. & Finance, vol. 1, no. 2, Mar. 25, 1922, pp. 378–380, 2 figs. Design by A. H. Sproule which overcomes some of previous losses.

Rotary. The Planche Rotary Compressor (Compresseur rotatif, systeme R. Planche), Lucien Fournier. Génie Civil, vol. 80, no. 12, Mar. 25, 1922, pp. 275–277, 10 figs. Describes rotary air compressor based on principle of conchoidal motion of a disk-piston, and gives results of tests.

AIRPLANE ENGINES

Detonation. The Background of Detonation, Stanwood W. Sparrow. Aerial Age Weekly, vol. 15, no. 9, May 8, 1922, pp. 201–203, 206, 4 figs. Discussion of charge temperatures and pressures before and after combustion.

Installation. Engine Installation, Bagnall-Wild Aeronautical Jl., vol. 26, no. 136, Apr. 1922, pp. 121–129 and (discussion) 130–136, 1 fig. Discusses lack of development. Principal features required for evolution of a sound installation, and how far these aims may be realized in the light of present-day experience.

Large-Bore. An American Development in Large-Bore Aircraft Engines, Herbert Chase. Automotive Industries, vol. 46, no. 16, Apr. 20, 1922, pp. 852–856, 4 figs. Wright Aeronautical Corp. design for Navy Zeppelin-type ships which develops 400 b.hp. at 400 r.p.m. Accessibility for repair in air one of outstanding features.

Light-Weight. Special Light-Weight Aero Engine A. E. L. Chorlton. Aeronautical Jl., vol. 26, no. 136, Apr. 1922, pp. 137–148, 1 fig. Discusses the more important types of engines and gives principal characteristics in tables.

Starting at Low Temperatures. Starting Aircraft Engines at Low Temperatures. Aviation, vol. 12, no. 18, May 1, 1922, p. 505. Abstract from technical memorandum no. 29, Canadian Air Board, by Prof. Robb at Edmonton, Alberta.

Wright Six-Cylinder. The Wright 6-Cylinder Airship Engine. Aviation, vol. 12, no. 18, May 1, 1922, pp. 504–505, 1 fig. First American high-power airship engine develops 350–400 hp. and has low fuel and oil consumption.

AIRPLANE PROPELLERS

Design. Notes on Propeller Design, Max M. Munk. Aerial Age Weekly, vol. 15, nos. 8 and 10, May 1 and 15, 1922, pp. 178–179 and 225–226. May 1: Energy losses, in particular that of friction between air and blade. May 15: Distribution of thrust over a propeller blade. Tech. Note N.A.C.A.

Theory. The Theory of the Screw Propeller, A. Betz. Aerial Age, vol. 15, no. 5, Apr. 10, 1922, pp. 105–106, 2 figs. Discusses our inadequate geometrical presentation and mathematical treatment of hydrodynamical phenomena connected with propeller and shows possibility of investigating phenomena in vicinity of propeller so as to be able to calculate its action on basis of fewer experimental values. Translated from Die Naturwissenschaften, No. 18, by N.A.C.A.

Variable Pitch. The "Universal Propeller," David L. Bacon. Aerial Age Weekly, vol. 15, no. 7, Apr. 24, 1922, pp. 152–153, 3 figs. Brief description of developments by Spencer Heath. May also be used in helicopters.

AIRPLANES

Commercial. The Commercial Aeroplane, W. H. Sayers. Aeroplane, vol. 22, nos. 5, 6, 8, 10, 11, 12 and 15, Feb. 1, 8, 22, Mar. 8, 15, 22 and Apr. 12, 1922, pp. 83–84, 99–100, 138, 171–172, 191–194, 207–208 and 263–264, 4 figs. Feb. 1: Deficiencies of present type of aircraft, and need for radical improvement in aerodynamic and structural design. Feb. 8: Incentives to stagnation in design. Feb. 22: Arrest of aerodynamic development. Mar. 8: Where research has so far failed. Mar. 15: How airplane can be improved Mar. 22: A possible type of economical airplane.

Flight Phenomena. Mechanical Phenomena of the Airplane in Flight (Mechanische Vorgange beim fliegenden Flugzeug), H. Schuster. Glasers Annalen, vol. 90, nos. 5 and 6, Mar. 1 and 15, 1922, pp 67–71 and 83–89 and (discussion) pp. 89–90, 29 figs. Review of what has been accomplished in fathoming secrets of flight phenomena. Deals with action of air forces on bodies and surfaces, especially effect of air resistance on aerofoil; design and stability of aerofoils; azimuth and altitude steering; high-altitude motors, etc.

Fire Elimination. Eliminating Fires in Airplanes, C. H. Butman. Aviation, vol. 12, no. 18, May 1, 1922, p. 508. Special study of subject by Air Service shows considerable progress made in past year.

Guiding Through Fog. The Loth Guide Cable for Flying in Fog. Aviation, vol. 12, no. 15, Apr. 10, 1922, pp. 422–423, 3 figs. Fundamental principle rests on fact that if high-frequency a.c. current is sent through cable earthed at each end, a magnetic field is created, which can be detected by receivers in airplane. System similar to directing ships in fog.

Handley Page W. 8b. The Handley Page W. 8b. Aeroplane, vol. 22, no. 16, Apr. 19, 1922, pp. 280–281, 12 figs. Description of design to be used on Handley Page service, modification of well-known W. 8.

Suspended Wing for Test. Aeroplane Will Carry Suspended Wing in Test. Aerial Age Weekly, vol. 15, no. 7, Apr. 24, 1922, p. 151. Full size wing to be tested for first time at Langley Field Laboratory of Nat. Advisory Com. for Aeronautics. Inverted and supported from plane by three wires.

Theory of Stability. A Theory and Its Proof, G. A. Spratt. Aviation, vol. 12, no. 18, May 1, 1922, pp. 510–511, 2 figs. Some theoretical considerations in the design of gliding and soaring aircraft, especially low-power sport airplanes.

Wibault Night Bomber. The Wibault Night Bombing Biplane, John Jay Ide. Aviation, vol. 12, no. 18, May 1, 1922, p. 509. French two-seater fitted with 600-hp. Renault engine has useful load to total weight ratio of 52 per cent.

AIRSHIPS

Non-Rigid. Trials of Goodyear Type AC Airship. Aviation, vol. 12, no. 14, Apr. 3, 1922, pp. 395–396. Nonrigid military airship of novel type makes successful trials at Goodyear-Akron air station; Aeromarine 130 hp. U6D engines; volume, 185,000 cu. ft.; speed, 65 m.p.h.; propeller speed, 775 r.p.m.

Rigid. Rigid Airships in the United States Navy, R. G. Pennoyer. U. S. Naval Inst. Proc. vol. 48, no. 4, Apr. 1922, pp. 517–529. Brief historic sketch. Cause of crashing of ZR-2. A German rigid for U. S. Some facts and figures on latest types; performance; value to Navy.

Surface Area. Determination of Surface Area for Airships, Edward P. Warner. Aviation, vol. 12, no. 16, Apr. 17, 1922, pp. 450–451, 1 fig. Discusses use of Lieutenant Diehl's formula.

Testing Models. Hydrostatic Test of an Airship Model. Aerial Age Weekly, vol. 15, no. 7, Apr. 24, 1922, pp. 154–155, 158, 166, 4 figs. Goodyear Rubber Co. model studies with both ballonets empty, forward ballonet filled with air, rear ballonet filled with air, and both ballonets filled with air.

ALLOYS

Aluminum. See ALUMINUM ALLOYS.

Calite. Calite—A New Heat Resisting Alloy. Automotive Industries, vol. 46, no. 18, May 4, 1922, p. 955. New heat-resisting alloy containing aluminum, nickel and iron which resists oxidization up to 2200 deg. fahr.

Cobalt-Tungsten. Cobalt-Tungsten Alloys (Kobalt-Wolframlegierungen), Karl Kreitz. Metall u. Erz, vol. 19, no. 6, Mar. 22, 1922, pp. 137–140, 1 fig. A diagram of state for cobalt-tungsten alloys is

plotted and conditions for obtaining a faultless casting are determined.

Electrochemistry. The Electrochemistry of Metal Alloys (Die Elektrochemie der Metallegierungen), R. Kremann. Metall, no. 3, Mar. 10, 1922, pp. 53-55. Effect of precipitation on behavior and composition of alloys.

Nickel. See NICKEL ALLOYS.

Zinc. See ZINC ALLOYS.

ALUMINUM

Plate, Decomposition. Decomposition of Aluminum Plate (Zersetzungserscheinungen an Aluminiumblechen), H. Kropf. Metall-Technik, vol. 48, no. 8-9, Feb. 23, 1922, pp. 68-69. Gives results of investigations carried out by Prof. Heyn and Bauer on three different kinds of aluminum plate showing signs of decomposition.

ALUMINUM ALLOYS

Aluminum-Silicon. Aluminum-Silicon Alloys, Zay Jeffries. Chem. & Met. Eng., vol. 26, no. 16, Apr. 19, 1922, pp. 730-734, 15 figs. Coming into use because of superior casting qualities; history, technical properties, and characteristics.

Alloys of Aluminum with Silicon, H. Sutton. Metal Industry (Lond.), vol. 20, no. 16, Apr. 21, 1922, pp. 365-366, 2 figs. Some investigations of ternary and more complex alloys.

Bronzes. Aluminum Bronze, An Alloy of Strength. William Dent Williams. Raw Material, vol. 5, no. 3, Apr. 1922, pp. 105-109, 15 figs. Discusses an alloy of 90 per cent Cu and 10 per cent Al, its properties, macrographic examination, casting, etc. Taken from Revue de Metallurgie.

Cerium, Influence of. Influence of Cerium on Aluminum and Other Light Metal Alloys, Josef Schulte. Metal Industry (N. Y.), vol. 20, no. 4, Apr. 1922, pp. 142-144, 1 fig. Describes experiments carried out with view to improving melting and soldering of light metals. Translated from Metall und Erz, May 22, 1921.

Failure, Cases of. Some Cases of Failure in "Aluminum" Alloys, W. Rosenhain. Metal Industry (N. Y.), vol. 20, No. 4, Apr. 1922, p. 140, 2 figs. Shows that many of aluminum alloys which fail are not really aluminum alloys. Read before British Inst. Metals.

High Strength. New Aluminum Alloys of High Strength. Chem. & Met. Eng., vol. 26, no. 15, Apr. 12, 1922, pp. 689-694, 5 figs. Digest of eleventh report of Alloys Research Committee of British Instn. Mech. Engrs. Properties of some alloys; permanence and constitution of alloys, age-hardening with magnesium and silicon.

"Y Alloy." Y Alloy (Aluminum-Copper-Nickel-Magnesium). Chem. & Met. Eng., vol. 26, no. 17, Apr. 26, 1922, pp. 785-787, 6 figs. A light aluminum alloy having strength of soft steel and good ductility; easy to cast and roll; retains its desirable properties in gas-engine parts working at 250 deg. cent.; immune from season cracking and corrosion.

AMMONIA

Refrigerating Capacity of. A Pound of Ammonia, John E. Starr. Refrig. World, vol. 57, no. 4, Apr. 1922, pp. 11-12. Method by which amount of refrigeration can be computed directly from weight of ammonia boiled per hour.

AMMONIA COMPRESSORS

Dry and Wet Methods. Operating Ammonia Compressors, W. S. Doan. Refrig. World, vol. 57, no. 4, Apr. 1922, pp. 17-18, 3 figs. Relative merits of two methods of compression.

APPRENTICES, TRAINING OF

New Plan. A Constructive Apprenticeship Movement. Sheet Metal Worker, vol. 13, no. 5, Mar. 31, 1922, pp. 153 and 161. Discusses new plan approved by employer and employee, in operation in New York, and recommended by New York Building Congress.

ASBESTOS

Utilization of Waste. The Utilization of Asbestos Waste. India-Rubber Jl., vol. 63, no. 15, Apr. 15, 1922, pp. 13-14, 1 fig. Difference of asbestos from other organic fiber makes this special problem. Suggestions of various uses for same.

ASH HANDLING

Plants. Ash-Removal Plants for Furnaces (Entaschungsanlagen für Feuerungen), P. Ledar. Wärme, vol. 45, no. 2, Jan. 13, 1922, pp. 31-33, 14 figs. Describes recent German and English patented improvements.

ASPHALT

Trinidad's Pitch Lake. Trinidad's Famous Pitch Lake, Col. H. A. Judd. Petroleum Times, vol. 7, no. 171, Apr. 15, 1922, pp. 501-502, 4 figs. Description giving some idea of its value as a source of supply.

ATOMS

Artificial. Artificial Disintegration of the Elements, Ernest Rutherford. Chem. Soc. Jl., vol. 121-122, no. 713, Mar. 1922, pp. 400-415, 4 figs. Concludes that atoms are such stable structures and nuclei are held together by such powerful forces that only most concentrated source of energy like the α-particle is likely to be effective in an attack.

AUTOGENOUS WELDING

Preheating. Preheating in Autogenous Welding (Über das Vorwärmen bei der autogenen Schweissung), Theo. Kautny. Autogene Metallbearbeitung, vol. 15, no. 3, Feb. 1, 1922, pp. 25-30, 8 figs. Advantages of preheating; describes Acme preheater, built by Lausanne Machine Co.

AUTOMOBILE ENGINES

Assembling. Methods Used in the Assembling of 150 Engines per Day, J. Edward Schipper. Automotive Industries, vol. 46, no. 15, Apr. 13, 1922, pp. 818-821, 11 figs. Describes assembling, inspection and testing operations and equipment employed in fabricating powerplant of Jewett car.

Heavy-Oil. A Heavy-Oil Automobile Engine (Un moteur d'automobile a huile lourde). Nature, no. 2499, Feb. 25, 1922, pp. 115-120, 4 figs. Describes the Peugeot engine which operates on kerosene, mazout or vegetable oils and has smaller fuel consumption in addition.

Heavy-Oil. The Peugeot Heavy-Oil Automobile Engine (Der Peugeot-Automobilmotor für Schwerölbetrieb), Lachmann. Motor U. Auto, vol. 19, no. 6, Mar. 31, 1922, pp. 81-86, 4 figs. Can be operated on 400 to 1600 revolutions; is of hot-bulb type; provided with special atomizer giving a perfect mixture.

Manufacture. Manufacturing Practice on Light Motor-car Power Units. Machy. (Lond.), vol. 19, nos. 493, 494 and 496, Mar. 9, 16 and 30, 1922, pp. 685-688, 723-731 and 781-787, 34 figs. Practice of Hotchkiss et Cie, Coventry, in connection with manufacture of 11.9 hp. light car power units for Morris Motors, Ltd., including tooling arrangements, works organization, arrangement of plant, etc.

Oil-Cooled. British Oil-Cooled Car Engines, M. W. Bourdon. Automotive Industries, vol. 46, no. 16, Apr. 20, 1922, pp. 849-851, 3 figs. Description of oil-cooled engines developed by G. M. Bradshaw, English airplane engine expert. Claimed to have all advantages of air-cooled engine and none of drawbacks.

Stutz. New Stutz Engine More Powerful; Higher Maximum Car Speed. Motor Age, vol. 41, no. 15, Apr. 13, 1922, pp. 16-17, 5 figs. Better handling of fuel, lighter and shorter pistons, better water circulation.

AUTOMOBILE FUELS

Alcohol and Gasoline Mixtures. Using Mixtures of Alcohol and Gasoline in Engines (Note sur l'utilisation, dans les moteurs, des mélanges d'alcool et d'essence), Nicolardot. Technique Automobile et Aérienne, vol. 12, no. 115, 1921 and vol. 13, no. 116, 1922, pp. 116-124 and 18-21, 9 figs. No. 115: Discusses solubility of alcohol in gasoline and experiments made for French war office. No. 116: Gives curve diagrams for solubility limits of alcohol, gasoline, benzol, and explains their application.

Detonation. Detonation—A Consideration of Its Causes, Stanwood W. Sparrow. Automotive Industries, vol. 46, no. 18, May 4, 1922, pp. 951-955, 5 figs. Consideration of tendency of fuel to detonate. Effect of explosion pressure, spark advance and other related factors.

Naphthalene. Hydrated Naphthalene as Automobile Fuel (Hydriertes Naphthalin als Betriebsstoff fur Automobile), J. Formànek. Allgemeine Automobil-Zeitung, vol. 23, no. 10, Mar. 11, 1922, pp. 27-29. Describes experiments made which show that tetraline and decaline mixed with benzol and benzene can be used to advantage; tetraline is superior to benzene or benzol.

AUTOMOBILES

Angus-Sanderson 14 Hp. The 14 Hp. Angus-Sanderson Car. Auto, vol. 27, no. 14, Apr. 6, 1922, pp. 283-285, 10 figs. Outstanding features of this London-built vehicle.

Automatic Chassis Lubrication. An Automatic Chassis Lubricating System. Automotive Industries, vol. 46, no. 18, May 4, 1922, pp. 950, 1 fig. New Chalco system does away with oil and grease cups on chassis.

Body Types, Names for. S.A.E. Standard Names for Body Types. Motor Age, vol. 41, no. 18, May 4, 1922, pp. 24-25, 14 figs. S.A.E. committee on body names has reported to parent society and names given have been adopted as standard by that organization.

Diatto 10-Hp. The 10 Hp. Diatto. Auto, vol. 27, no. 13, Mar. 30, 1922, pp. 263-265, 11 figs. Italian car built of British steel and with British body. Engine is of monobloc type with all valves on one side; it has four cylinders, 66-mm. bore, and piston stroke is 90 mm., giving cubic capacity of swept volume of 1017 cc.

Differential, Compensating. A New Type of Compensating Differential. Automotive Industries, vol. 46, no. 16, Apr. 20, 1922, pp. 857-858, 3 fig. Description of Krohn differential, which allows maximum differential action at low-axle speed and increasing resistance at greater r.p.m.

Dynamometer Test, Rear-Wheel. Rear Wheel Dynamometer Tests and Their Significance to the Engineer, Herbert Chase. Automotive Industries, vol. 46, no. 16, Apr. 20, 1922, pp. 859-868, 27 figs. Description and data from apparatus in Mason Laboratory, Sheffield Sci. School, Yale Univ. Includes comments on rolling friction, wind resistance, tractive effort, and fuel economy.

Gear Ratio 1914-1922. Rear Axle Gear Ratios of Passenger Cars from 1914 to 1922. Motor Age, vol. 41, no. 18, May 4, 1922, pp. 48-51, 1 fig. Tables of gear ratios for passenger cars by the year.

German Manufacture. The Stoewer Works, Stettin, Germany, and Their Products (Die Stoewer-Werke A.-G. und ihre Erzeugnisse). Motor u. Auto, vol. 19, no. 5, Mar. 15, 1922, pp. 68-72, 8 figs. Products consist of four- and six-cylinder automobiles, motor trucks, tractors and plows. Details of engines, etc.

Light Cars, French. Trend of French Cycle Cars and Light Cars, W. F. Bradley. Automotive Industries, vol. 46, no. 15, Apr. 13, 1922, pp. 801-806, 10 figs. Heavy taxes on automobiles increases interest in cycle cars, tendency toward 4-cylinder water-cooled type, with standard transmission and drive.

Maintenance. Aircraft Maintenance as a Standard for Motor Car Maintenance, P. L. Dumas. Motor Age, vol. 41, no. 14, Apr. 6, 1922, pp. 30-36, 11 figs. Importance of accuracy of tolerances and rigid inspection. Serious consequences of trivial omissions. Function of log book, tolerance sheet and timing disk.

Suspension Springs. Design and Functioning of Laminated Automobile Suspension Springs, A. A. Remington. Automotive Industries, vol. 46, nos. 14 and 15, Apr. 6 and 13, 1922, pp. 757-763 and 807-812, 21 figs. Also Automobile Engr., vol. 12, no. 162, Apr. 1922, pp. 118-127, 21 figs. Apr. 6: Character of laminated springs, and their theoretical and actual functioning; suggestions for improvement in design. Apr. 13: Deals with different spring steels, and gives specifications for standard testing procedure of raw spring material and finished product. Paper, slightly condensed, read before Instn. Automobile Engrs.

A Spring Suspension Which Secures Greater Flexibility. Automotive Industries, vol. 46, no. 18, May 4, 1922, p. 969, 1 fig. In this spring suspension system practically entire sprung weight is supported on two equalizing bars, one at each end of chassis. It is claimed that all rolling is eliminated and after-bounding is damped out.

Transmission Production. An Efficient Method of Transmission Production, J. Edward Schipper. Automotive Industries, vol. 46, no. 16, Apr. 20, 1922, pp. 869-872, 13 figs. Methods employed in Hudson and Essex Transmission Dept. Drilling of cases and machining of gear blanks accomplished by labor-saving methods. Gears matched for best mesh by special testing device.

AVIATION

Aerial Navigation. The Basic Principles of Aerial Navigation (Ueber die Grundlagen der Nautik des Luftmeeres), Conrad Harmsen. Schiffbau, vol. 23, nos. 14, 15, 17 and 18, Jan. 4, 11, 25 and Feb. 1, 1922, pp. 403-408, 435-439, 495-501 and 533-538, 10 figs. Study based on author's experiences during war. Comparison of general nautical and aeronautical principles. Discussion and graphic solution of three most important problems of aerial navigation.

Commercial Airways. The Development of Commercial Airways, Henry White-Smith. Inst. of Transport Jl., vol. 3, no. 3, Mar. 1922, pp. 145-163 and (discussion) 164-170. Summarizes development of air service in Great Britain and other countries and points out some possibilities.

Maps and Navigation. Maps and Navigation Methods, A. Duval. Aerial Age Weekly, vol. 15, no. 9, May 8, 1922, pp. 198-199. International agreement as to maps and merits of flying by compass rather than landmarks. From Preimer Congrès International de la Navigation Aérienne, Nov. 1921.

Sperry Flight Indicator. The Sperry Flight Indicator. Aviation, vol. 12, no. 14, Apr. 3, 1922, pp. 393-394, 1 fig. Describes instrument built for flying in fog and in clouds which combines features of turn indicator and inclinometer.

B

BEAMS

Continuous. Method for Calculating Lines of Influence of Bending Moments of Continuous Beams (Verfahren zur Ermittlung von Einflusslinien der Biegungsmomente durchlaufender Träger), H. Kayser. Beton u. Eisen, vol. 21, no. 4, Feb. 23, 1922, pp. 56-60, 12 figs. Describes simple method of calculating lines of influence for beams with unsymmetrical opening having no particular ratio to one another and for varying moments of inertia.

T-Shaped Cross-Sections. Method for Measuring T-Shaped Cross-Sections (Bemessungsverfahren für T-förmigen Querschnitt), Franz Kardos. Beton u. Eisen, vol. 21, no. 4, Feb. 23, 1922, pp. 62-65, 4 figs. Presents chart for measurement of T-shaped cross-sections and describes its applications.

BEARING METALS

Babbitt, Pouring Temperature for. Definite Temperature Control Necessary in Babbitt Pouring, Karl F. Smith. Elec. World, vol. 79, no. 18, May 6, 1922, pp. 886-887. Challenge of article on "Suggestions on Rebabbitting Bearings," by M. M. Brown, p. 434 of Elec. World, Mar. 4.

BEARINGS

Frictional Resistance of Lubricated. The Synthetic Calculation of Frictional Resistances of Lubricated Bearings (Die synthetische Berechnung der Reibungswiderstände geschmierter Lager, Etc.), W. v. Dallwitz-Wegner. Zeit. für technische Physik, vol. 3, no. 1, 1922, pp. 21-28, 8 figs. Calculation to determine properties of lubricating oil, based on internal friction of lubricating oil and capillary properties of oil and bearing metal.

Unsymmetrical. Pressures in Unsymmetrical Bearings, A. W. Knight. Machy. (Lond.), vol. 19, no. 496, Mar. 30, 1922, pp. 789-790, 2 figs. Makes calculations from which it is concluded that it is bad practice to use unsymmetrical bearings of whatever proportions.

BEARINGS, ROLLER

Railway Motors. Roller Bearings for Railway Motors (Wälzlager für Bahnmotoren), H. Mecke.

Zeit des Vereines deutscher Ingenieure, vol. 66, no. 12, Mar. 25, 1922. pp. 269-274, 23 figs. Notes on first experiments with ball bearings; ball and roller bearings for railway motors and advantages of latter.

BELTING

Care and Splicing. Splicing and Care of Leather, Rubber and Canvas Belts, G. H. Radebaugh. Coal Age, vol. 21, no. 17, Apr. 27, 1922, pp. 687–690, 25 figs. Oak-tanned leather preferable for power transmission; why short-lap belt is recommended; tallow and cod-liver oil make good dressing; cement, wire and rawhide fastenings.

Leather. Leather Belt Research Conclusions, J. Edgar Rhoads. Can. Mfr., vol. 42, no. 4, Apr. 1922, pp. 25–26. Manufacturers have conducted investigations into various phases of uses of leather belting, results of which are outlined.

V-Type. New Belt That May Revolutionize Drives to Light Machinery, Roger Fison. Belting, vol. 20, no. 4, Apr. 1922, pp. 26–28, 1 fig. Due to greater friction surface and flexiblity this type can transmit much greater power under less tension than round belt. Hints on other sizes.

Widths, Relative Capacity. Relative Capacity of Leather Belts of Different Widths, Belting, vol. 20, no. 4, Apr. 1922, pp. 36–38, 1 fig. Experiments by R. S. Jones of Leather Belting Exchange Foundation, Cornell Univ. Power transmitted increased from 22 at end of 9 hr. to 57 at end of 47½ hr. Capacity apparently varies directly with width.

BLAST-FURNACE GAS.

Cleaning. Economy of Modern Blast-Furnace-Gas Cleaning Processes in the Rhur and Minette Districts (Wirtschaftlichkeit neuzeitlicher Hochofengasreinigungen im Ruhr- und Minettebezirk), Max Schlipköter. Stahl u. Eisen, vol. 42, nos. 8 and 11, Feb. 23 and Mar. 16, 1922, pp. 285–290 and 408–422, 4 figs. 1 on supp. plate. Advantages of use of well-purified gases in air heating. Influence of water content of gases. Requirements of blast-furnace gas for economical operation. Determination of operating costs of cleaned gases based on practical examples with different cleaning processes. Advantages of dry filter process.

BLAST FURNACES

Oxygen Admixture to Air. The Admixture of Oxygen to Blast in Blast-Furnace Plants (Verwendungsmöglichkeiten der Lindeluft in Hochofenbetrieben), Theodor Wagner. Stahl u. Eisen, vol. 42, no. 12, Mar. 23, 1922, pp. 456–460. Notes on earlier opinions and experiments; changed conditions in blast-furnace practice since war; reduction of coke charge and introduction of producer gas or pulverized coal through tuyeres; use of air rich in oxygen in blast furnaces with pulverized-coal heating.

BOILER FEEDWATER

Preheating. Preheating of Locomotive Feedwater (Les réchauffeurs de l'eau d'alimentation des locomotives). Génie Civil, vol. 80, no. 14, Apr. 8, 1922, 320–324, 8 figs. Compares open and closed types and discusses American practice.

Regulator, Automatic. Hydraulic Feed-Water Automatic Regulator. Mar. Engr. & Naval Architect, vol. 45, no. 535, Apr. 1922, pp. 169. Some features of new Aster-Anthony hydraulic feedwater regulator.

Self-Cleaning Evaporator Coils. Self Cleaning Evaporator Coils. Am. Mar. Engr., vol. 17, no. 5, May 1922, p. 33. Reilly evaporator, submerged type, self-scaling coil solved problem of accumulation of salt scale.

Treatment of Water. Boiler Water, C. E. Joos and A. W. Binns. Power Plant Eng., vol. 26, nos. 9 and 10, May 1 and 15, 1922, pp. 456–460 and 511–514, 23 figs. May 1: Up-to-date methods of eliminating impurities which cause trouble in boilers. May 15: Priming, its causes and their relative importance; continuous determination of steam quality.

BOILER FIRING

Brown Coal. Boiler Firing with Brown Coal (Feuerungsanlagen für Rohbraunkohlen), O. Binder. Wärme- u. Kälte-Technik, vol. 24, no. 6, Mar. 15, 1922, pp. 65–67, 4 figs. Suitable firebox and grate arrangements; mechanical stoking; etc.

Peat. Firing Peat Under Boilers with Inclined Grate and Automatic Stoking (Die Verfeuerung von Torf in einer Schrätiger Beschickung unter Luftabschluss), W. Ledler. Wärme, vol. 45, no. 10, Mar. 10, 1922, pp. 121–124, 2 figs. Describes furnace built by Varel Iron Wks., near Oldenburg, and gives results of number of evaporation tests.

Pure and Mixed Peat Fuel for Boiler Firing (Reine und gemischte Torffeuerung in Dampfkesselfeuerungen). Rauch u. Staub, vol. 12, no. 6, Mar. 1922, pp. 53–56. Adaptation of firebox conditions to burning of peat, and advantages of peat in firing with brown coal and other low-grade fuels.

BOILER OPERATION

Load Indicators. Indicating Station Load in the Boiler Room, F. F. Leilich. Power, vol. 55, no. 15, Apr. 11, 1922, pp. 579–580, 4 figs. Automatic load indicator is described which has made it possible to hold steam pressures within prescribed limits under fluctuating loads and practically to prevent safety valves popping off.

Sugar Factories. Boiler House Operation in Sugar Factories (Kesselhauswirtschaft in Zuckerfabriken), H. Berner. Wärme, vol. 45, no. 3, Jan. 20, 1922, pp. 41–47, 11 figs. Deals with inherent difficulties in sugar factories; advantage of high boiler pressure; heat storage; saving of fuel through use of heating-gas preheater; high-pressure economizers, also for low-pressure boilers; forced-draft installations; practical tests on gas losses in anthracite furnaces; efficiency of the Eimert boiler-tube nests.

BOILERS

Cleaning. Cleaning Boilers by Means of Sand-Blast Apparatus (Reinigung von Dampfkesseln durch Sandstrahlgebläse), W. Kaempfer. Technische Blätter, vol. 12, no. 15, Apr. 14, 1922, pp. 153–154, 6 figs. Describes various experiences, especially with cleaning locomotive boilers; process requires about 200 kg. of sand per hr.

Furnace. See FURNACES, BOILER.

Locomotive. See LOCOMOTIVE BOILERS.

Marine. See MARINE BOILERS.

Settings. Progress in Boiler Setting (Fortschritte auf dem Gebiete der Dampfkesseleinmauerung), W. Ritter. Feuerungstechnik, vol. 10, no. 12 Mar. 15, 1922, pp. 125–126. Describes innovations in boiler brickwork.

Upkeep of Idle. Upkeep of Idle Boilers (La conservation des chaudieres en chomage), V. Kammerer. Bul. des Associations Françaises de Propriétaires d'Appareils a Vapeur, no. 3, Jan. 1921, pp. 133–138. Precautionary measures to keep out rust, contact with air or water, etc.

BOILERS, WATER-TUBE

Marine. A New American Water-Tube Boiler for Capital Ships. Mar. Engr. & Naval Architect, vol. 45, no. 535, Apr. 1922, pp. 150–153 and 154–155, 2 figs. Features of experimental boiler designed by Rear-Admiral Dyson, U. S. N. and tested by Phila. Navy Yard.

BRAKES

Freight-Train, French. The Question of Continuous Brakes in the French Freight Trains (Die Frage der durchlaufenden Bremse für Güterzüge in Frankreich), H. Pechot. Organ für die Fortschritte des Eisenbahnwesens, vol. 77, no. 2, Jan. 15, 1922, pp. 17–22. Discusses experiments with air and vacuum brakes on French railways; also the Clayton Hardy, Kunze-Knorr, Westinghouse, and other brakes. Pp. 22–25, criticism by A. Führ.

BRASS

Cold Strip Rolling. American Practice in Cold Rolling Brass Strip, C. E. Davies. Metal Industry (Lond.), vol. 20, no. 13, Mar. 31, 1922, pp. 293–297, 2 figs. Points out that main points of difference in American from English practice are (1) machining or overhauling cast ingot before rolling; (2) increased rolling speeds; and (3) improved methods and appliances for handling and cleaning metal.

BROACHES

Pull. The Design of Pull Broaches. Machy. (Lond.), vol. 20, no. 497, Apr. 6, 1922, pp. 13–15, 4 figs. Depth of cut; pitch of teeth; length; shape of teeth; methods of attaching broaches to machines.

BRONZES

Cast, Analysis of. Notes on the Analysis of Cast Bronze, G. E. F. Lundell and J. A. Scherrer. Jl. of Indus. & Eng. Chem., vol. 14, no. 5, May 1922, pp. 426–429. Desirable procedures and precautions often ignored. Based on work done at Bur. of Stand. and by coöperating analysts.

BUSES

Gasoline-Electric, England. Gasoline-Electric Bus with Unusual Features Operated in England. Bus Transportation, vol. 1, no. 5, May 1922, pp. 283–284, 2 figs. Description of type carrying gasoline engine, dynamo and electric motor.

C

CABLEWAYS

Aerial Passenger. Suspended Railways for Passenger Service in Comparison with Surface Mountain Railways (Drahtseilschwebebahnen zur Beförderung von Personen im Vergleich zu ebenerdigen Bergbahnen), H. Gatzweiler. Verkehrstechnik, vol. 39, no. 12, Mar. 24, 1922, pp. 142–145, 3 figs. Describes Bleichert system of suspended cableway and points out advantages of such systems.

CALORIMETERS

Continuous-Flow. A Continuous-Flow Calorimeter, and the Determination of the Heat of Neutralization of a Solution of Hydrochloric Acid by one of Sodium Hydroxide, Frederick G. Keyes, Louis J. Gillespie and Shinroku Mitsukuri. Am. Chem. Soc. Jl., vol. 44, no. 4, Apr. 1922, pp. 707–717, 3 figs. Describes experiments carried out and apparatus used.

CALORIMETRY

Bomb Corrosion. The Effect of Bomb Corrosion on the Accuracy of Calorimetric Determinations, H. L. Olin and R. E. Wilkin. Chem. & Met. Eng., vol. 26, no. 15, Apr. 12, 1922, pp. 694–696. Describes experiments made with nickel-lined bombs.

CAMS

Calculation Calculation of Cams (Calcul des cames), Octave Lepersonne. Technique Automobile et Aerienne, vol. 12, nos. 113 and 114, 1921, pp. 33–42 and 68–71, 15 figs. No. 113: Discusses theory, determination of geometric form, application of straight line and arc profiles. No. 114: Graphic calculation and numerical examples.

CARS

Design Problems. Springs, Draft Gears and Other Problems in Car Design, Louis E. Endsley. Ry. Rev., vol. 70, no. 17, Apr. 29, 1922, pp. 591–594, 3 figs. Shorter spring travel and longer draft-gear travel suggested as solution to most serious problem. Address before Virginia Section of A.S.M.E.

Restaurant and Sleeping. Restaurant and Sleeping Cars for the Siamese State Railways. Ry. Gaz., vol. 36, no. 13, Mar. 31, 1922, pp. 554–556, 11 figs. partly on pp. 559–560. Designed to afford maximum comfort to travelers; workmanship of highest class.

CAST IRON

Early History. The Early History of Iron with Special Reference to Cast Iron, J. Newton Friend. Foundry Trade Jl., vol. 25, nos. 290, 291 and 292, Mar. 9, 16 and 23, 1922, pp. 182–183, 193–194 and 216–218, 9 figs. Discusses iron in Egypt and Palestine, Mesopotamia, Europe, Great Britain and Central Africa; direct reduction of iron ores; reduction of iron in Africa; discovery of cast iron; 18th century developments.

Mechanical Tests. Mechanical Tests of Cast Iron (Considérations générales sur les essais mécaniques des fontes), M. Portevin. Révue Universelle des Mines, vol. 12, no. 6, Mar. 15, 1922, pp. 507–511. Discusses the various tests available and shows that some, such as the impact test, are of no value. Recommends tensile strength and Brinell tests.

CEMENT

Canadian Specifications. New Cement Specifications, Canadian Engineering Standards Association. Can. Engr., vol. 42, no. 17, Apr. 25, 1922, pp. 428–429. Résumé of new report from Can. Standards Assn. based also on specifications of Eng. Inst. of Canada, Am. Soc. for Testing Matls., and Brit. Standards for Portland Cement.

Fused. Fused Cement (Le Ciment fondu). Vie Technique et Industrielle, vol. 3, no. 30, Mar. 1922, pp. 503–506, 4 figs. Discusses French process for making cement containing 10 per cent silica, 40 alumina, 10 iron oxide, 40 lime, raised to temperature of complete fusion, and its properties and characteristics.

Hardening. Experiments on the Effect of Low Temperatures on the Hardening of Cement (Versuche über die Einwirkung von niedrigen Temperaturen auf das Erhärten des Zements), H. Kreüger. Beton u. Eisen, vol. 21, no. 5, Mar. 18, 1922, pp. 74–78, 4 figs. Discusses tests with cement cubes to show effect of freezing temperature and draws number of conclusions.

CENTRAL STATIONS

Heating and Power. Investigating the Efficiency of a Central Heating and Power Station (Wirtschaftliche Untersuchungen an einem Fern-Wärmekraftwerk), M. A. Nüscheler. Gesundheits-Ingenieur, vol. 45, no. 13, Apr. 1, 1922, pp. 169–177, 5 figs. Author's experience in construction and operation of steam piping for central heating stations, either in connection with central power stations or without it.

Superpower. Superpower System for Japan, C. A. Powel. Elec. Rec., vol. 31, no. 5, May 1922, pp. 357–359, 1 fig. Program for furnishing electricity over large area between Tokio and Osaka.

Hoover Sees Super-Power Project as Possible Stabilizer of Coal Industry. Min. Congress Jl., vol. 8, no. 5, May 1922, pp. 729–730. Theory that project in Atlantic Coast region between Washington, D. C. and Portland, Me., might stabilize coal industry.

CHIMNEYS

Heat Losses in. The Relation Between CO_2 and Stack Losses. Power Plant Eng., vol. 26, no. 8, Apr. 15, 1922, pp. 429–431, 3 figs. Discusses various factors governing chimney loss, and shows that the magnitude of chimney loss bears definite relation to percentage of CO_2 in flue gases.

CLUTCHES

Magnetic. Magnetic Clutches in the Cement Industry, W. H. Costello. Am. Inst. Elec. Engrs. Jl., vol. 41, no. 5, May 1922, pp. 361–363, 2 figs. Clutch requirements and description of magnetic type which meets them.

Systems. Study of the Various Clutch Systems (Étude des divers systèmes d'embrayages), Henri Petit. Technique Automobile et Aerienne, vol. 13, no. 116, 1922, pp. 4–17; 28 figs. Describes English and American gear systems for automobiles, including cone clutches and disk clutches, and gives tabulated statement of their characteristics.

COAL

Analysis. Coal Analyses May Be Misleading Because of Crude and Insufficient Sampling, O. P. Hood. Coal Age, vol. 21, no. 12, Mar. 23, 1922, pp. 484–486. Advises averaging of numerous samples taken over long period to get representative value. Based on address before Nat. Assn. Purchasing Agents.

Coking Propensities. The Coking Propensities of Coals, W. A. Bone, A. R. Pearson, E. Sinkinson, W. E. Stockings. Gas World, vol. 76, no. 1967, Apr. 1, 1922, pp. 16–20, 1 fig. Results of experimental investigations into resinic constituents of bituminous coals and their supposed determining influence upon coking propensities of coals. (Abstract.) Paper read before Royal Soc.

Combustion. Combustion of Coal, R. B. MacMullin. Combustion, vol. 6, no. 3, Mar. 1922, pp. 118–123, 5 figs. Composition and classification of coal; oxidation of carbon.

Recovery from Ashes of Coke and. Recovery of Coke and Coal From Ashes (Rückgewinnung von Koks und Kohlen aus Asche), Ullrich. Montanistische Rundschau, vol. 14, nos. 3 and 7, Feb. 1 and Apr. 1, 1922, pp. 56–58 and 153–156, 7 figs. Describes electromagnetic ash separators and shaking tables, and gives results of some experiments with ashes from anthracite firing at experiment station of Krupp-Gruson works.

Sampling. Sampling Fuel (Prélèvement et préparation d'un échantillon moyen de combustibles) Bul. des Associations Françaises de Propriétaires d'Appareils à Vapeur, no. 6, Oct. 1921, pp. 330–331, 1 fig. Procedure adopted by French associations for drawing and preparing average sample of coal.

COAL GAS

Economical Use. Economical Use of Illuminating Gas (L'emploi économique du gaz d'éclairage), R. Villers. Nature, no. 2500, Mar. 4, 1922, pp. 134–138, 7 figs. Various uses of the gas, types of burners, proper mixing with air, compressing.

COAL HANDLING

Bunkering Cranes. Recent Developments in Bunkering Cranes, Cargo, Coal Loading Equipment and Shipbuilding Cranes, Justin Green. World Ports, vol. 10, no. 6, Apr. 1922, pp. 47–53. Describes methods for bunkering coal at various harbors.

Equipment. Coal and Ash-Handling Equipment, Harry R. Westcott. Steam, vol. 29, no. 4, Apr. 1922, pp. 93–100. Description of various units from yard storage through traveling bridges, feeders, chain elevators and conveyors to ash hoppers.

COAL STORAGE

Methods. Coal Storage (La conservation des charbons), E. Schmidt. Bul. des Associations Françaises de Propriétaires d'Appareils à Vapeur, no. 4, Apr. 1921, pp. 163–181. Discusses change in coal exposed to air, spontaneous combustion, storage under water, coal piles, etc.

COKE BREEZE

Steam Generation. The Utilization of Coke Breeze for the Generation of Steam, W. Francis Goodrich. Gas Engr., vol. 38, no. 530, Feb. 15, 1922, pp. 44–46. Features of this fuel which make it of real value.

COLD STORAGE

Indirect Air Cooling. Indirect Air Cooling for Cold Storage—A Problem in Design, H. E. Corl. Refrigeration, vol. 29, no. 8, Mar. 1922, pp. 26–28, 1 fig. Considerations necessary in design; refrigeration; bunker coil surfaces, selection of fan and motor; thermostatic control of temperature.

COMBUSTION

Coal. Combustion of Coal, R. B. MacMullin. Combustion, vol. 6, no. 5, May 1922, pp. 224–228, 4 figs. Relation between temperature, excess air, and rate of combustion.

COMPRESSED AIR

Mines. Determining the Drop in Pressure in Compressed Air Piping in Mines (Ermittlung des Druckabfalls in Pressluftleitungen untertage), W. Reinhard. Glückauf, vol. 58, no. 15, Apr. 15, 1922, pp. 433–436, 1 fig. Discusses drop due to pipe resistance, and gives chart from which average loss of head can be calculated.

CONDENSERS, STEAM

Steam. Season Cracking in Condenser Tubes. Power Plant Eng., vol. 26, no. 9, May 1, 1922, pp. 461–462, 6 fig. Cracking of tubes. Study of costs and suggestions toward elimination.

CONVEYORS

Belt. Biggest Belt-Conveyor System in the World, D. R. Egbert. Belting, vol. 20, no. 4, Apr. 1922, pp. 17–25, 5 figs. Parcel-post station in Chicago to be completed June 1922, will have 8 miles canvas-stitched belting. Description of installation, largest in world.

Monorail. Monorail Conveyors on Clay Plants. Brick and Clay Rec., vol. 60, no. 8, Apr. 18, 1922, pp. 613–615, 9 figs. This type desirable for clay plants. Description of installations at R. Thomas & Sons, East Liverpool, Ohio, and Brooklyn (Ind.) Brick Co.

Steel-Belt. Flexible Steel Belt Conveyors, Harry Carlson. Gas Age-Rec., vol. 49, no. 13, Apr. 1, 1922, pp. 283–285, 6 figs. Describes steel belt made by Sandviken Steel Works, Sweden, and gives particulars as to strength, corrosion, loading width, etc.

Steel-Band Conveyors. Eng. Progress, vol. 3, no. 5, May 1922, pp. 109–110, 13 figs. Application and advantages of steel-band conveyors of Sandviken type.

Telphers vs. Telphers vs. Conveyors for Gas Works Purposes, Herbert Blyth. Gas. Engr., vol. 38, no. 549, Jan. 16, 1922, pp. 6–7, 2 figs. Features of gas manufacturing plant and comparative advantages of overhead telphers and conveyor systems.

COOLING TOWERS

Recooling of Water in. Recooling Plants (Ueber Rückkühlanlagen), Fritz Hoyer. Wärme, vol. 45, no. 6, Feb. 10, 1922, pp. 77–80, 7 figs. Desiderata for obtaining good results from cooling installations. Details and advantages of modern types.

CORROSION

Colloids, Influence of Protective. The Influence of Protective Colloids on the Corrosion of Metals and on the Velocity of Chemical and Physical Change, John A. N. Friend and Reece H. Vallance. Chem. Soc. Jl., vol. 121–122, no. 713, Mar. 1922, pp. 466–474, 2 figs. Concludes that after a general law protective colloids tend to retard velocity of such reactions as involve change of state from solid to liquid, or vice versa, in one or more of the components.

Ferrous Metals. Corrosion of Ferrous Metals, Robert Abbott Hadfield. Metal Industry (Lond.), vol. 20, no. 16, Apr. 21, 1922, pp. 381–382. Preparation of various ferrous metals used in corrosion research of Inst. Civil Engrs. together with their physical and mechanical properties and some general considerations on subject of corrosion. (Abstract.) Paper read before Inst. Civil Engrs.

Rust Prevention. The Prevention of Rust. Motor Transport, vol. 34, no. 896, May 1, 1922, p. 529, 1 fig. Notes on application of thermozine process for protecting certain parts of motor vehicles against corrosion.

Oxidization Prevention. Calorizing and Calite, G. H. Howe and G. R. Brophy. Gen. Elec. Rev., vol. 25, no. 5, May 1922, pp. 267–272, 5 figs. Description of process developed in Schenectady Research Laboratory to prevent corrosion.

COST ACCOUNTING

Depreciation and Retirement of Property. Depreciation and Retirement of Property, William H. Bell. Jl. of Accountancy, vol. 33, no. 4, Apr. 1922, pp. 253–258. Shows that where average rate of depreciation is used, if a unit of property is retired in advance of average estimated life of all units in its class, entire cost of unit retired should be charged to reserve for depreciation.

Engineering Methods Applied to. Engineering Methods Applied to Cost Finding, Robert S. Denham. Indus. Management, vol. 63, nos. 2, 3, 4 and 5, Feb., Mar., Apr. and May, 1922, pp. 67–73, 161–166, 218–220, and 310–312, 4 figs. Feb.: Effect upon profit margin of traditional and misleading cost methods. Mar.: General principles underlying application of expense items. Apr.: Six fundamental principles of cost engineering. May: Definite procedure for surveying the requirements of production.

Factory. Factory Accounts, Costs, and Statistics, R. Dunkerley. Foundry Trade Jl., vol. 25, nos. 293 and 294, Mar. 30 and Apr. 6, 1922, pp. 233–235 and 248–249. Comparative factory expenses; underlying principles and essential details; foundry tackle; monthly statements; individual costs; overhead charges; wasters; etc.

New Plan. Cost Accounting, Guy Foote Wetzel. Armour Engr., vol. 13, no. 3, Mar. 1922, pp. 163–171. Discusses cost accounting plan with some new features, by A. W. Torbet, installed in large manufacturing plant, and compares with usual methods.

Scientific, Necessity for. Costing in Industry. Eng. & Indus. Management, vol. 7, no. 12, Apr. 20, 1922, pp. 357–360. First part of special report of Costing Conference held in Lond., covering cost accountant's position, works expenditure, periodical comparisons, and productive labor.

COTTON INDUSTRY

Electrical Equipment. The Electrical Equipment of the D. R. Cotton Mills. Electrician, vol. 88, no. 2292, Apr. 21, 1922, pp. 473–474, 4 figs. Some details of mills which contain both spinning and weaving sections.

CRANES

Classification. Classification of Hoisting Machines Particularly Cranes (Einteilung der Hebe- und Transportmaschinen, insbesondere der Krane), R. Dub. Fördertechnik u. Frachtverkehr, vol. 15, nos. 1 and 2, Jan. 6 and 20, 1922, pp. 1–4 and 22–26, 59 figs. Classification of the various types of cranes into groups according to their kinematic characteristics, assuming that load is always concentrated at center of gravity.

Floating. A 60-ton Floating Crane, W. Fox. Mech. World, vol. 71, nos. 1837 and 1838, Mar. 17 and 24, 1922, pp. 207–209 and 224–226, 10 figs. Describes in detail revolving jib type floating crane, built by Werf Gusto (Firma A. F. Smulders), Schiedan, Holland.

Inspection. Things that the Crane Inspector Looks for and Some of the Hows and Whys, A. L. Gear. Elec. Rev. & Indus. Engr., vol. 80, no. , Mar. 1922, pp. 111–118, 152, 14 figs. Inspection report forms and things looked for in making inspection.

Wrecking. Ten-Ton Locomotive Steam Breakdown Crane. Engineer, vol. 133, no. 3457, Mar. 31, 1922, p. 357, 3 figs. partly on p. 360. Built by Bedford Engineering Co., Bedford, England, for Great Western of Brazil Ry., and designed to lift loads up to 10 tons at radius of 20 ft.

CRANKSHAFTS

Steel for. Steel for Crankshafts: Its Heat Treatment, H. C. Loudenbeck. Forging & Heat Treating, vol. 8, no. 4, Apr. 1922, pp. 181–183. Grades of steel that are being used for this purpose, and their heat treatment and physical properties to secure best results.

CUPOLAS

Charging Elevator, Combined with. An Improved Foundry Melting Plant. Engineer, vol. 133, no. 3457, Mar. 31, 1922, pp. 365–366, 3 figs. Describes plant designed by J. E. Hurst for regular production of high-grade cast iron for use in manufacture of castings by centrifugal-casting process. Consists of a cupola, an elevator charging arrangement and an oil-fired receiver.

Design and Operation. Iron and Foundry Cupola Management, J. J. McClelland. Foundry Trade Jl., vol. 25, no. 292, Mar. 23, 1922, pp. 209–213, 5 figs. Author's experience in cupola practice; describes layout of plant, construction of cupola, linings, charging, fans or blowers, etc. Paper read before Instn. British Foundrymen.

Iron Melting. Cupola Practice, J. Wood. Foundry Trade Jl., vol. 25, nos. 296 and 297, Apr. 20 and 27, 1922, pp. 288–290 and 304–306, 3 figs. Some difficulties that have to be overcome in melting iron by cupola process which, for quickness and cheapness, is not excelled by any other furnace. Details of lining and tuyeres. Paper read before Instn. British Foundrymen.

D

DIESEL ENGINES

Flexibility. Diesel Engine Flexibility, W. S. Burn. Steamship, vol. 33, no. 394, Apr. 1922, pp. 320–331, 9 figs. Investigation with view to its application to direct-driven Diesel locomotive. It is shown that principles governing flexibility are practically identical with those governing economy. Read before Graduate Section of North-East Coast Instn. Engrs. & Shipbuilders.

Generator Drive. Oil-Engine-Driven Ship Generators in the German Navy (Der ölmotorische Antrieb von Borddynamos in der deutschen Kriegsmarine), W. Laudahn. Schiffbau, vol. 23, nos. 13, 14, 15, 16, 19–20, 21, 23 and 25–26, Dec. 28, 1921, and Jan. 4, 11, 18, Feb. 8–15, 22, Mar. 15 and 22–29, 1922, pp. 363–369, 397–403, 429–435, 467–470, 565–573, 605–611, 745–752 and 777–780, 93 figs. Dec. 28: The 300-kw. Diesel engine built by Körting Bros., Inc., for liner, König. Jan. 4: Engine of Fried. Krupp Corp. Germania Shipyard for liner Kronprinz. Jan. 11 and 18: Engine of Benz & Co., Mannheim, for liner Bayern. Feb. 8: Engine of Vulcan Works, Inc., Hamburg for liner Wurttemberg. Feb. 22: Engine of Augsburg-Nürnberg Corp. for large cruiser. Lützow. Mar. 15 and 22: Engine of Görlitzer Machine Constr. & Iron Foundry Corp. for large cruiser Hindenburg.

Heavy and Low-Grade Oil. Using Heavy and Low Grade Oil in Motors of the Diesel Type (Mineria y Petróleo), Benigno Benigni. Ingenieria, vol. 26, no. 3, Mar. 1922, pp. 133–135, 1 fig. Some experiments with Ansaldo San Giorgio engines running on cotton-seed and palm oils.

Lighter. Use Diesel Unit for Lighter. Mar. Rev., vol. 52, no. 5, May 1922, pp. 215–217, 3 figs. Installation of unit on derrick lighter Worthington, owned by Worthington, Pump & Machy. Corp. develops 300 b.hp. at 275 r.p.m.

Locomotive. Industrial and Scientific Progress. Beama, vol. 10, no. 4, Apr. 1922, pp. 295–298. Description of air auxiliary cylinders with Diesel engine which give sufficient flexibility for use on locomotives; designed by W. S. Burn who presented paper on subject before N. E. Coast Instn. Engrs. & Shipbuilders.

Marine. A 1000-Hp. Marine Diesel Engine of the German Works, Inc. (Ein 1000 PS-Schiffs-Dieselmotor der Deutschen Werke A.-G.), P. Stephan. Motor u. Auto, vol. 19, no. 5, Mar. 15, 1922, pp. 65–68, 2 figs. Also Schiffbau, vol. 23, no. 27, Apr. 5, 1922, pp. 815–824. Describes engine recently completed in Kiel shipyard which is one of two engines to be installed in a tanker with 8000-ton displacement built for the Italian Government. It is 6.6 m. high and has six 4-stroke single-acting cylinders.

Injection and Combustion of Fuel-Oil—IX, C. J. Hawkes. Motorship, vol. 7, no. 5, May 1922, pp. 366–367, 4 figs. Experiments with solid-injection and air-blast in marine Diesel engines. (Concluded.)

The Beardmore-Tosi Diesel Engine. Steamship, vol. 33, no. 394, Apr. 1922, pp. 332–338, 9 figs. Presents table showing relative cost of fuel, oil, and personnel for two types of vessels, one steam-driven and the other Diesel-driven. Details of Beardmore-Tosi marine engines.

DRAFT

Equalized. The Significance of Equalized Draft (Wesen und Bedeutung des ausgeglichenen Zuges), Hch. Doevenspeck. Wärme, vol. 45, no. 9, Mar. 3, 1922, pp. 111–113, 2 figs. Discusses questions relating to natural and forced draft and advantages of equalized draft.

DRILLING MACHINES

Pneumatic. Pneumatic Drilling Machines and Hammers in Mining and Related Industries (Druckluft-Bohrmaschinen und -Hammer im Bergbau und in den verwandten Betrieben), R. Goetze. Zeit. des Vereines deutscher Ingenieure, vol. 66, nos. 11 and 12, Mar. 18 and 25, 1922, pp. 245–251 and 278–280, 42 figs. History of development and description of most important modern types of drilling machines, hammers and picks. Prospects of future development.

DROP FORGINGS

Difficulties. How Drop Forgings are Made Perfect, J. H. G. Williams. Raw Material, vol. 5, no. 4, May 1922, pp. 140–143, 14 figs. Summarizes chief difficulties in production of faultless drop forgings. Paper presented at N. Y. Sectional Meeting of Am. Soc. for Steel Treating.

Modern Practice. Modern Drop-Forging Practice—II. Machy. (Lond.), vol. 10, no. 487, Jan. 26, 1922, pp. 508–511, 7 figs. Deals with trimming of forgings and correct forging heats, and gives typical examples of drop-forging work.

DRYING

Wood. Note on Drying (Note sur le séchage), P. Villain. Révue de l'Industrie Minérale, no. 31, Apr. 1, 1922, pp. 155–170, 10 figs. General principles of drying methods as applied in mining and metallurgy, especially of woods.

DURALUMIN

Properties and Commercial Possibilities. Duralumінum Properties and Commercial Possibilities. Brass World, vol. 18, no. 4, Apr. 1922, pp. 129–130. Characteristics of this material, one-third the weight of cold-rolled steel though with same approximate strength.

Welding. Welding Duralumin—Some Experimental Work and Its Results, Horace C. Knerr. Automotive Industries, vol. 46, no. 18, May 4, 1922, pp. 964–968, 10 figs. Account of experimental work done at Naval Aircraft Factory and results attained from this work and from weld made by private firm. Details of tensile and corrosion tests made on different types of welds.

E

EDUCATION, INDUSTRIAL

Electricians. Practical Training and Professional Courses in the Electric Industries (Role de l'École pratique et des Cours professionnels dans les industries électriques), E. Labbé. Révue Générale de l'Électricité, vol. 11, nos. 10 and 11, Mar. 11 and 18, 1922, pp. 367–372 and 405–414, 10 figs. Mar. 11: Kind of training best for practical industrial schools to train skilled electricians. Mar. 18: Machinery and apparatus necessary for instruction, and their practical operation.

ELECTRIC DRIVE

Changing from Steam. Changing From Steam to Electric Drive. Wood-Worker, vol. 41, no. 2, Apr. 1922, pp. 38–39, 1 fig. In case cited herewith a large plant changes from steam to electric drive, but instead of scrapping old power-transmission equipment, latter is retained in sections which now constitute motor-driven group drives.

ELECTRIC FURNACES

Aluminum Melting. Melts Aluminum in Electric Furnace, H. E. Diller. Foundry, vol. 50, no. 9, May 1, 1922, pp. 345–357, 10 figs. Daily and monthly operating reports indicate power required and other data. Core sand all reused; sand driers prove economical; patterns fitted in wooden matches.

Annealing. Regenerative Car Type Electric Furnace, A. D. Dauch. Forging & Heat Treating, vol. 8, no. 4, Apr. 1922, pp. 200–201, 4 figs. Describes annealing furnace of Fowler and Union Horse Nail Co., Buffalo, N. Y.

Electromagnetic Motion. Electromagnetic Motions in Electric Furnaces. Brass World, vol. 18, no. 4, Apr. 1922, pp. 117–119. Method of applying in practice forces suggested in paper by Carl Hering, read at Apr. 1921 meeting of Am. Electrochem. Society.

Non-Ferrous. Non-Ferrous Electric Furnaces, F. Kilburn and H. C. Dews. Foundry Trade Jl., vol. 25, no. 296, Apr. 20, 1922, pp. 281–282. Furnaces for low-melting-point alloys, below 800 deg. cent.; for medium-melting-point alloys, between 800 to 1,300 deg. cent.; and for high melting point alloys, above 1300 deg. cent. (Abstract.) Paper read before West Yorkshire Metallurgical Soc.

Operation. Changes in the Working of an Electric Furnace (Remarques au sujet des changements d'allure dans les hauts-fourneaux électriques), J. Seigle. Révue de Métallurgie, vol. 19, no. 2, Feb. 1922, pp. 86–89. Difference in blast and electric furnaces in reduction of oxides by carbon and formation of CO and CO_2.

Resistance-Type, Graphites for. Electric-Resistance Furnace for High Temperatures (Elektrisk motståndsugn for höga temperaturer), Bo Kalling. Teknisk Tidskrift (Utgiven av Svenska Teknologföreningen), vol. 52, no. 9, Mar. 4, 1922, pp. 146–148, 3 figs. Resistance of Acheson and Scandinavian graphites at various temperatures.

ELECTRIC LOCOMOTIVES

Chile Freight Service. Electric Freight Locomotives for Chile. Ry. Age, vol. 72, no. 17, Apr. 29, 1922, pp. 1005–1006, 2 figs. Work on fifteen for Chilean State Rys. nearing completion. Operated at 3000 volts d.c.; maximum speed, 40 m.p.h.; estimated weight, 226,000 lb.

Electric Locomotives for Chile Freight Service, F. E. Wynne. Elec. Ry. Jl., vol. 59, no. 16, Apr. 22, 1922, pp. 667–672, 15 figs. Details of road and switching locomotives soon to be delivered to Chilean State Rys. are given. Designs provide for incorporation into present railway system while not preventing further standardization.

Single-Phase, France. Single-Phase Electric Traction on the System of the Camargue R. R. Co. (Application de la traction électrique par courant monophasé sur le réseau de la Compagnie des Chemins de Fer de la Camargue), J. Reyval. Révue Générale de l'Électricité, vol. 11, no. 10, Mar. 11, 1922, pp. 351–359, 12 figs. Discusses recently electrified lines Nîmes-Arles Trinquetaille and Nîmes-Saint Gilles, and advantages derived; 6600 volts, 25 cycle.

ELECTRIC PLANTS

Hell Gate Station. Hell Gate—A Station of Many Features. Elec. World, vol. 79, no. 17, Apr. 29, 1922, pp. 821–827, 11 figs. Unusual features are turbine room next to river, phase isolation of all electrical equipment, alternating-current-driven auxiliaries.

Humanized. A Humanized Plant, R. C. Denny. Combustion, vol. 6, no. 5, May 1922, pp. 218–220, 4 figs. Cannon St. plant of New Bedford Gas & Edison Light Co. designed for best performance of man power and mechanical equipment and operating at 1.7 lb. of 14,000 B.t.u. New River Coal to the kw.

Winnipeg River. The Next Big Western Power Scheme. Contract Rec., vol. 63, no 17, Apr. 26, 1922, pp. 372–375, 6 figs. Manitoban Power Co. actively developing Great Falls, Winnipeg River. Contracts let for two complete 28,000 hp. units. Complete capital cost will be less than $80 per hp.

ELECTRIC POWER

Scientific Application to Factory Problems. Applying Electricity Scientifically to Factory Problems, Louis F. Leurey. Jl. Electricity & West. Industry, vol. 48, no. 9, May 1, 1922, pp. 343–345, 3 figs. Example of what can be done in adapting electricity to special needs of a factory as illustrated by modern equipment and carefully planned layout of California and Hawaiian sugar plant.

ELECTRIC RAILWAYS

Track and Wiring on Bridge. Track and Wiring on Large Bridge. Elec. Ry. Jl., vol. 59, no. 14, Apr. 8, 1922, pp. 587–591, 11 figs. Describes overhead wire and track construction on new bridge across Housatonic River, which has just been completed by Connecticut Co.

EMPLOYEES' REPRESENTATION

Works Councils. Industrial Representation and the Fair Deal. George H. Shepard. Indus. Management, vol. 63, nos. 2, 3, Feb., Mar. 1922, pp. 81–85, 185–188. Deals with fundamentals of contact with employees to stimulate production. Coöperation by managers and employees through works councils.

ENGINEHOUSES

Chesapeake & Ohio. New Locomotive Facilities at Clifton Forge, Va. Ry. Age, vol. 72, no. 16, Apr. 22, 1922, pp. 955–958, 13 figs. New 10-stall installation at Clifton Forge, Va., which includes power house capable of 1100 b.hp., storehouse and oil house.

EXECUTIVES

Functions and Methods of Chief. A Technique for the Chief Executive, John H. Williams. Taylor Soc. Bul., vol. 7, no. 2, Apr. 1922, pp. 47–68. Notes on responsibilities and duties of chief executive and a method through which he might function effectively.

Problem of Chief. The Problem of the Chief Executive, Henry P. Kendall. Taylor Soc. Bul., vol. 7, no. 2, Apr. 1922, pp. 39–46. From point of view of medium-sized enterprise.

EXPORT TRADE

Packing for. Packing for Export, P. J. Burns. World Ports, vol. 10, no. 6, Apr. 1922, pp. 69–75. Discusses prevention of pilfering and damage, marking and packing of shipments, and coöperation between exporters and transportation companies.

F

FANS

Mine. Selection of Fans for Pipe Ventilation, Walter S. Weeks. Eng. & Min. Jl.-Press, vol. 113, no. 119, May 13, 1922, pp. 816–818, 3 figs. Theory of operation and calculations to be made in choosing equipment for assuring proper supply of pure air and for fire fighting; computation of characteristic curves at different speeds; discussion limited to small fans.

FEEDWATER HEATERS

Locomotive. Locomotive Feed Water Heaters, H. B. Oatley. Southern & Southwestern Ry. Club, vol. 16, no. 7, Jan. 19, 1922, pp. 14–37 and (discussion) pp. 37–45, 19 figs. General discussion of development and prospects, with suggestions as to operation.

FIRE HOSE

Coupling Standardization. Progress in Hose Coupling Standardization, F. M. Griswold. Nat. Fire Protection Assn., vol. 15, no. 3, Jan. 1922, pp. 246–249. Discusses importance of standardization in fire-fighting equipment.

FIRE PREVENTION

Automatic Devices. Automatic Devices for Preventing Fires in Buildings (Dispositifs automatiques de protection des édifices contre l'incendie), Jacques Michaut. Génie Civil, vol. 80, no. 13, Apr. 1, 1922, pp. 295–299, 8 figs. Deals with sprinkler systems such as Grinnell type, automatic fire alarms, etc.

Fire-Alarm Code. Many Changes Planned for Fire Alarm Code, C. E. Beach. Fire & Water Eng., vol. 71, no. 18, May 3, 1922, pp. 727–728, 730 and 742. Comment on proposed changes in fire alarm code by former engineer of large fire alarm establishment.

Water Supply, Relation of. Fire Service as it Relates to Water Supply, Dow R. Gwinn. Mun. & County Eng., vol. 62, no. 4, Apr. 1922, pp. 148–154. Several features of water problem in this field.

FLIGHT

Soaring. Flying Without Engine (Étude théorique du vol sans moteur), Alayrac. Aeronautique, vol. 4, no. 34, Mar. 1922, pp. 75–78. Discusses theory of gliding and wind conditions, and reduces it to mathematical formulas.

The Velocity of Descent of Gliding Airplanes (Zur Sinkgeschwindigkeit von Segelflugzeugen) Erik Thomas. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol. 13, no. 6, Mar. 31, 1922, pp. 78, 4 figs. Gives mathematical determination of minimum velocity of descent for gliding plane whose area is constant, and for gliding plane whose spread of wings is constant.

FLOW OF WATER

Weirs. Experiments With Flow Over Weirs With End Contractions (Expériences sur des déversoirs a nappe libre avec contraction latérale), V.-M. Hegly. Annales des Ponts et Chaussées, vol. 6, Nov.-Dec. 1921, pp. 290–389, 43 figs. Gives results of measurements of flow for triangular, semicircular, multiple, and other discharges in connection with Marne-Saône canal.

FLYING BOATS

Amphibian. The Supermarine Single-Seater Fighting Scout "Sea King" Mark II. Flight, vol. 14, no. 16, Apr. 20, 1922, pp. 226–229 and 236, 13 figs. Description of interesting amphibian flying boat with 300-hp. Hispano-Suiza engine.

FOUNDRIES

Castings, Cost of. System Keeps Tab on Foundry Costs, H. C. Keller. Foundry, vol. 50, no. 8, Apr. 15, 1922, pp. 308–310 and 315, 9 figs. Outlines simplified method for finding costs of castings; suitable for small shops.

Handling Products. Heavy Tonnage from a Small Floor. Foundry, vol. 50, no. 8, Apr. 15, 1922, pp. 301–307, 10 figs. Discusses coördination of supply of materials and sequence of operation as essential to molding and pouring of castings.

Heating Units, Manufacture of. Heater Sections Made in Quantity. Foundry, vol. 60, no. 7, Apr. 1, 1922, pp. 267–274, 12 figs. System of providing large and continuous vents in cores automatically removes most dangerous factor in producing castings of this character.

FUELS

Automobile. See AUTOMOBILE FUELS.

Hogged. Hogged Fuel, Emery A. Morrison. Power Plant Eng., vol. 26, no. 8, Apr. 15, 1922, pp. 407–410, 4 figs. Its heat-producing value; design and adaptability of furnace; means and method of handling fuel to furnace grates. From paper read before Western Section of Am.Soc.Mech.Engrs.

Low-Grade. Contributions to the Improvement of German Fuel Economy (Beiträge zur Verbesserung der deutschen Brennstoffwirtschaft), Otto Brandt. Wärme (formerly Zeit. für Dampfkessel u. Maschinenbetrieb), vol. 45, nos. 4, 5 and 6, Jan. 27, Feb. 3 and 10, 1922, pp. 53–55, 68–71 and 81–83. Discusses use of peat, lignite and other low-grade fuels and design of furnaces for their use; distribution and efficient exploitation of high-grade fuels; utilization of German crude oil; water-power utilization, etc. Future prospects.

PreCarbonization. Precarbonization of Fuels (La carbonisation préalable des combustibles). Outillage, vol. 253, no. 13, Apr. 1, 1922, pp. 377–380, 4 figs. Low-temperature carbonization; tar distillation; low-grade fuels, etc.

[See also COAL; GAS; LIGNITE; OIL FUEL; PULVERIZED COAL.]

FURNACES, BOILER

Oil. New Oil Furnaces (Neue Oelfeuerungen), H. Pradel. Wärme (Zeit. für Dampfkessel u. Maschinenbetrieb), vol. 45, no. 1, Jan. 6, 1922, pp. 10–12, 9 figs. Details of various types constructed by Körting Bros., Inc., near Hannover, Germany, including steam-jet centrifugal oil furnaces, low-pressure burners, etc.
